ELEVENTH EDITION

VOLUME XXVI

SUBMARINE MINES. A submarine mine is a weapon of war used in the attack and defence of harbours and anchorages. It may be defined as "A charge of explosives, moored at or beneath the surface of the water, intended by its explosion to put out of action without delay a hostile vessel of the class it is intended to act against." It differs from the torpedo (*q.v.*) in being incapable of movement (except in the special form of drifting mines, which are not moored, but move with the tide or current). But this subdivision into two distinct classes was not made till 1870. Prior to that date the teim "torpedo" was used for all explosive charges fired in the water.

Submarine mines may be divided into two main classes, controllable and uncontrollable, or, as they are often classified, "electrical" or "mechanical." In the first class the method of firing is by electricity, the source of the electric power whether by battery or dynamo being contained in a firing station on shore and connected to the mines by insulated cables. By simply switching off the electricity in the firing station, such mines are rendered inert and entirely harmless. In the second class, the means of firing are contained in the mine itself, the source of power being a small electric battery, or being cbtained from a pistol, spring or suspended weight. In all mines of this class the impulse which actuates the firing gear is given by a ship or other floating object bumping against the mine. When mechanical mines have once been set for firing they are thus dangerous to friend and foe alike. Safety arrangements are employed to prevent the firing apparatus working while the mine is being laid, and clockwork is sometimes added to render the mine inactive after a certain definite time or in case the mine breaks away from its mooring. Their principal advantages, as compared with the electrically controlled mines, are cheapness and rapidity of laying. "Controllable" mines are absolutely under the control of the operator on shore, their condition is always accurately known, and if any break adrift not only is the fact at once known but the mines themselves are harmless. Another advantage is that when fired by "observation" as described below, they are placed at depths which will be well below the bottom of any vessels passing through the mine field. They can thus be used in channels which have to be kept open for traffic during hostilities.

Electrical mines take rather longer to prepare and lay out than the other class, as the electrical cables have to be laid and jointed, and they require rather more skill and training in the operators employed to lay and fire the mines. Such mines represent the highest development of this form of warfare, and the details given below refer mainly to this class of mine.

Electrical mines are arranged on two systems according to the method of ascertaining the proper moment to apply the firing current to the mine cables. These methods are by "observation" or by "circuit closer."

The "observation" system depends on two careful observations made by an operator on shore, one of the exact position in which the mines are laid, the other of the track of hostile ships passing over the mine field. The position of the mines when laid is marked on a special chart, on which the track of ships crossing the mine field can also be plotted. When the track is seen to be crossing the position of a mine, a switch is closed on shore and the mine is fired. To allow for errors in observation such mines are fitted with large charges of explosive and are usually arranged in lines of two, three or four mines placed across the channel, all the mines in a line being fired together. Observation mines are placed either resting on the bottom or moored at depths which are well below the bottom of any friendly vessels and (except that anchoring in the mine field must be forbidden for fear of injury to cables) such mines offer no obstruction to friendly traffic.

In the "circuit closer" or "C.C." system, each mine contains a small piece of apparatus which is set in action by tbe blow of a vessel or other object against the mine. When set in action, this apparatus completes an electrical circuit in the mine, through which the mine can be fired, if the main switch on shore is closed. If it is not wished to fire, the C.C. is restored to its ordinary condition either automatically by a spring in the mine, or by an electrical device operated from the shore.

Such mines are necessarily placed near the surface, and are to this extent an interference with friendly traffic. A vessel passing by mistake through a mine field of this class would run no risk of an explosion while the mines are inactive, but might do some damage to the mines.

This class of mine is used in side channels which it is intended to close entirely, or to reduce the width of navigable channels where too wide to be defended by observation mines. Their principal advantage is that if the firing switch is closed they are effective in fog or mist, when observation mines could not be worked, and when the guns of the defence would be equally out of action. As they are fired only when close against the side of a ship, the charge can be comparatively small and the mines themselves are handy and easy to lay.

Compared with observation mines they use much less cable, as the action of the C.C. is such that only the mine which is struck can be fired. Several mines of this class can therefore share one cable from the shore, though in practice details of mooring and arrangement limit the number connected to one cable to four. A set of mines on one cable is referred to as a "group."

The arrangements for firing the mines are contained in a firing station on shore, in which is the battery or other source of electrical power for firing, and the necessary apparatus for testing the system of mines, which is usually done daily. To let the operator in the firing station know when the C.C. of a mine has been struck and the mine is ready to fire, a small electrical apparatus is provided in the firing station for each group of mines. This arrangement strikes a bell when the C.C. is worked and also closes a break in the firing circuit. The operator can then close the main switch and fire the mine, or if acting on the order to "fire all mines that signal" he has already closed his main switch, the signalling apparatus, in the act of striking the bell, completes the firing circuit. A similar piece of apparatus is connected to each observing instrument, the completion of the circuit of any line at the observing station then gives a signal in the firing station and the firing circuit is completed.

The firing station can be on a vessel moored near the mine field, but is more usually on shore, where it can be made absolutely secure against any form of attack. But the observing stations must be on shore to give stability to the observing instruments, they cannot be entirely protected as they must have a small opening facing the mine field, but can be made very inconspicuous.

Any explosive can be used in submarine mines, provided adequate means are taken to explode the charge, but the explosive which is easiest to handle and is in most general use is wet gun-cotton with a small dry primer and detonator to start ignition. The detonators for electrical mines are on the "low tension" system, that is, firing is effected by the heating of a small length of wire called a "bridge," round which is placed a priming which ignites and detonates a small charge of fulminate of mercury.

The charge is contained in a steel mine-case, which has an "apparatus" inside to contain the electrical arrangements and the C.C. when used. Cases for observation mines are usually cylindrical in shape for mines to rest on the bottom and spherical for buoyant mines. The weight of charge is about 500 ℔ and the size of a buoyant case for this charge would be four feet in diameter. Cases for contact mines are spherical, about 39 in. in diameter, and can hold 100 ℔ of gun-cotton. They are always buoyant. Buoyancy is provided for by an air-space inside the case. Buoyant cases are moored to a heavy weight or "sinker," the connexion being by a steel wire rope, or in electrical mines, the cable itself. The cable is carefully insulated and protected with a layer of steel wires. An earth return is used for the electrical circuit.

The employment of mines in any defence must depend entirely on the general character of the defence adopted, which will itself depend on the size and importance of the harbour to be defended and other details (see Coast Defence). The rôle of mines in a defence is to act as an obstacle to detain ships under fire and compel them to engage the artillery of the defence. Thus mines find their greatest usefulness in the defence of harbours with long channels of approach. Mine fields can be destroyed by "creeping" for and cutting the electric cables, by "sweeping" for the mines themselves with long loops of chain or rope or by destroying the mines with "countermines." To guard against any of these, the mine field should be protected by gun fire and lit at night by electric lights. As vessels sunk by mines may obstruct the channel, mines should not be used in very narrow channels.

Although the scientific development of submarine mining is the work of the last fifty years, attempts to use drifting charges against ships and bridges are recorded as early as the 16th century. Mines were used by the Americans in 1777, and in 1780 Robert Fulton produced an explosive machine which he called a "torpedo," and which was experimented with, not very successfully, up to 1815. In 1854 the Russians used mechanical mines in the Baltic, but without any marked success.

The first application of electricity to the explosion of submerged charges was made by Sir Charles Pasley in the destruction of wrecks in the Thames and of the wreck of the "Royal George" at Spithead in 1839 and subsequent years. The first military use of electrically-fired mines was made in the American Civil War of 1861–65 when several vessels were sunk or damaged by mines or torpedoes. From this date onwards most European nations experimented with mines, and they were actually used during the Franco-German War of 1870, the Russo-Turkish War of 1878 and the Spanish-American War of 1898. But the most interesting example of mine warfare was in the attack and defence of Port Arthur during the Russo-Japanese War (*q.v.*) of 1904–05. Both sides used mechanical mines only, and both suffered heavy losses from the mine warfare. Mines and torpedoes were first introduced into the English service about 1863, defence mines being placed in the charge of the Royal Engineers, while torpedoes were developed by the Royal Navy. Up to 1904 there were mine defences at most of the British ports, but in that year the responsibility of mines was placed on the navy, and since then the mine defences have been much reduced. (W. B. B.)

SUBSIDY (through Fr. from Lat. *subsidium*, reserve troops, aid, assistance, from *subsidere*, literally "to sit or remain behind or in reserve"), an aid, subvention, assistance granted especially in money. The word has a particular use in economic history and practice. In English history it is the general term for a tax granted to the king by parliament, and so distinguished from those dues, such as the customs dues, which were raised by the royal prerogative; of these subsidies there were many varieties; such was the subsidy in excess of the customs on wool, leather, wine or cloth exported or imported by aliens, later extended to other articles and to native exporters and importers (see Tonnage and Poundage); there was also the subsidy which in the 14th century took the place of the old feudal levies. Apart from this application the term, in modern times, is particularly applied to the pecuniary assistance by means of bounties, &c., given by the state to industrial undertakings (see Bounty). Subsidies granted by the state to literary, dramatic or other artistic institutions, societies, &c., are generally styled "subventions" (Lat. *subvenire*, to come to the aid of).

SUCCESSION (Lat. *successio*, from *succedere*, to follow after) the act of succeeding or following, as of events, objects, places in a series, &c., but particularly, in law, the transmission or passing of rights from one to another.

In every system of law provision has to be made for a readjustment of *things* or goods on the death of the human beings who owned and enjoyed them. Succession to *rights* may be considered from two points of view: in some ways they depend on the personality of those who are concerned with them: if you hire a servant, you acquire a claim against a certain person and your claim will disappear on his death. But personal relations are commonly implicated in the arrangement of property: if a person borrows money, the creditor expects to be paid even should the debtor die, and the actual payment will depend to a great extent on the rules as to inheritance. Succession, in the sense of the partition or redistribution of the property of a former owner is, in modern systems of law, the subject of many rules. Such rules may be based on the will of a deceased person. They will be found in such articles as Administration; Assets; Executors and Administrators; Inheritance; Intestacy; Legacy; Will; &c. There are cases, however, in which a will cannot be expressed; this eventuality is discussed in the present article, and there can be no doubt that it is the most characteristic one from the point of view of social conditions. It represents the view of society at large as to what *ought to be* the *normal* course of succession in the readjustment of property after the death of a citizen. We shall dwell chiefly on the customs of succession among the nations of Aryan stock. Other customs are noticed in the articles on Village Communities; Mahommedan Law; &c.

We have to start from a distinction between personal goods and the property forming the economic basis of existence for the family which is strongly expressed in early law. War booty, proceeds of hunting, clothes and ornaments, implements fashioned by personal skill, are taken to belong to a man in a more personal way than the land on which he dwells or the cattle of a herd.

It is characteristic that even in the strict law of paternal power formulated by the Romans an unemancipated son was protected in his rights in regard to things acquired in the camp (*peculium castrense*) and later on this protection spread to other chattels (*peculium quasi-castrense*). The personal character of this kind of property has a decisive influence on the modes of succession to it. This part of the inheritance is widely considered in early law as still in the power of the dead even after demise. We find that many savage tribes simply destroy the personal belongings of the dead: this is done by several Australian and Negro tribes (Post, *Grundriss der ethnologischen Jurisprudenz*, pp. 174–5). Sometimes this rule is modified in the sense that the goods remaining after deceased persons have to be taken away by strangers, which leads to curious customs of looting the house of the deceased. Such customs were prevalent, for example, among the North American Indians of the Delaware and Iroquois tribes. Evidently the nearer relations dare not take over such things on account of a *tabu* rule, while strangers may appropriate them, as it were, by right of conquest.

The continuance of the relation of the deceased to his own things gives rise in most cases to provisions made for the dead out of his personal succession. The habit of putting arms, victuals, clothes and ornaments in the grave seems almost universal, and there can be no doubt that the idea underlying such usages consists in the wish to provide the deceased with all matters necessary to his existence after death. A very characteristic illustration of this conception may be given from the customs of the ancient Russians, as described about 921 by the Arabian traveller Ibn Fadhlan. The whole of the personal property was divided into three parts: one-third went to the family, the second third was used for making clothes and other ornaments for the dead, while the third was spent in carousing on the day when the corpse was cremated. The ceremony itself consisted in the following: the corpse was put into a boat and was dressed up in the most gorgeous attire. Intoxicating drinks, fruit, bread and meat were put by its side; a dog was cut into two parts, which were thrown into the boat. Then, all the weapons of the dead man were brought in, as well as the flesh of two horses, a cock and a chicken. The concubine of the deceased was also sacrificed, and ultimately all these objects were burned in a huge pile, and a mound thrown up over the ashes. This description is the more interesting because it starts from a division of the goods of the deceased, one part of them being affected, as it were, to his personal usage. This rule continues to be observed in Germanic law in later times and became the starting point of the doctrine of succession to personal property in English law. According to Glanville (vii. 5, 4) the chattels of the deceased have to be divided into three equal parts, of which one goes to his heir, one to his wife and one is reserved to the deceased himself. The same reservation of the third to the deceased himself is observed in Magna Charta (c. 26) and in Bracton's statement of Common Law (fol. 60), but in Christian surroundings the reservation of " the dead man's part " was taken to apply to the property which had to be spent for his soul and of which, accordingly, the Church had to take care. This lies at the root of the common law doctrine observed until the passing of the Court of Probate Act 1857. On the strength of this doctrine the bishop was the natural administrator of this part of the personalty of the deceased.

The succession to real property, if we may use the English legal expression, is not governed by such considerations or the needs of the dead. Roughly speaking, three different views may be taken as to the proper readjustment in such cases. Taking the principal types in a logical sequence, which differs from the historical one, we may say that the aggregate of things and claims relinquished by a deceased person may: (1) pass to relatives or other persons who stood near him in a way determined by law. Should several persons of the kind stand equally near in the eye of the law the consequence would be a division of the inheritance. The personal aspect of succession rules in such systems of inheritance. (2) The deceased may be considered as a subordinate member of a higher organism—a kindred, a village, a state, &c. In such a case there can be no succession proper as there has been no individual property to begin with. The cases of succession will be a relapse of certain goods used by the member of a community to that community and a consequent rearrangement of rights of usage. The law of succession will again be constructed on a personal basis, but this basis will be supplied not by the single individual whose death has had to be recorded but by some community or union to which this individual belonged. (3) The aggregate of goods and claims constituting what is commonly called an inheritance may be considered as a unit having an existence and an object of its own. The circumstance of the death of an individual owner will, as in case 2, be treated as an accidental fact. The unity of the inheritance and the social part played by it will constitute the ruling considerations in the arrangement of succession. The personal factor will be subordinated to the real one.

In practice pure forms corresponding to these main conceptions occur seldom, and the actual systems of succession mostly appear as combinations of these various views. We shall try to give briefly an account of the following arrangements: (1) the *joint family* in so far as it bears on succession; (2) *voluntary associations* among co-heirs; (3) *division* of inheritance; (4) united succession in the shape of *primogeniture* and of *junior right*.

The large mass of Hindu juridical texts representing customs and doctrines ranging over nearly 5000 years contains many indications as to the existence of a *joint family* which was considered as the corporate owner of property and therefore did not admit in principle of the opening of succession through the death of any of its members. The father or head of such a joint family was in truth only the manager of its property during lifetime, and though on his demise this power and right of management had to be regulated anew, the property itself could not be said to pass by succession: it remained as formerly in the joint family itself. In stating this abstract doctrine we have to add that our evidence shows us in practice only characteristic consequences and fragments of it, but that we have not the means of observing it directly in a consistent and complete shape during the comparatively recent epochs which are reflected in the evidence. It is even a question whether such a doctrine was ever absolutely enforced in regard to chattels: even in the earliest period of Hindu law articles of personal apparel and objects acquired by personal will and strength fell to a great extent under the conception of separate property. Gains of science, art and craft are mentioned in early instances as subject to special ownership and corresponding rules of personal succession are framed in regard to them (Jolly, Tagore lectures on *Partition, Inheritance and Adoption*, 94). But on the other hand there are certain categories of movable goods which even in later law are considered as belonging to the family community and incapable of partition, *e.g.* water, prepared food, roads, vehicles, female slaves, property destined for pious uses and sacrifices, books. When law became rationalized these things had to be sold in order that the proceeds of the sale should be divided, but originally they seem to have been regarded as owned by the joint family though used by its single members. And as to immovables—land and houses—they were demonstrably excluded in ancient customary law from partition among co-heirs.

In Greek law the most drastic expression of the joint family system is to be found in the arrangements of Spartan households, where brothers clustered round the eldest or " keeper of the hearth "[1] (ἑστιαπάμιον), and not only the management of family property but even marriages were dependent on the unity of the shares and on the necessity of keeping down the offspring of the younger brothers. With the Romans there are hardly any traces of a primitive family community excluding succession, but the Celtic tribal system was to a great extent based on this fundamental conception (Seebohm, *Tribal System in Wales*).

[1] The term illustrates the intimate connexion between inheritance and household religion in ancient Aryan custom.

During three generations the offspring of father, grandfather and great-grandfather held together in regard to land. The consequence was that, although separate plots and houses were commonly reserved for the uses of the smaller families included within the larger unit, the death of the principal brought about an equalization of shares first *per stirpes* and ultimately *per capita* until the final break-up of the community when it reached the stage of the great-grandsons of the original founder. But the most elaborate system of family ownership is to be observed in the history of the latest comers among the Aryan races—the Slavs. In the backward mountain regions which they occupied in the Balkan Peninsula and in the wilderness of the forests and moors of Eastern Europe they developed many characteristic tribal institutions and, among these, the joint family, the *Zadruga, inokoshtina*. The huge family communities of the southern Slavs have been described at length by recent observers, and there can be no doubt that their roots go back to a distant past (see VILLAGE COMMUNITIES). There is no room in them for succession proper: what has to be provided for is the continuity of business management by elders and the repartition of rights of usage and maintenance, a repartition largely dependent on varying customs and on the policy of the above-mentioned elders. In Russia the so-called *large family* appears as a much less extensive application of the same idea. It extends rarely over more than three generations, but even as a cluster of members gathering around a grandfather or a great-uncle it presents an arrangement which hampers greatly private enterprise and staves off succession until the moment when the great household breaks up between the descendants of a great-grandfather.

In Germanic law we catch a glimpse of a state of things in which side relations were not admitted to succession at all. The Frankish Edict of Chilperic (A.D. 571) tells us that if somebody died without leaving sons or daughters, his brother was to succeed him and not his neighbours (*non vicini*). This has to be construed as a modification of the older rule according to which the neighbours succeeded and not the brother. Under "neighbours" we cannot understand merely people connected with a person by proximity of settlement, but rather his kinsmen in their usual capacity of neighbours. The fact that kinsmen forming a settlement have precedence of such near relations as the brothers is characteristic enough, especially, as even the succession of sons and daughters is mentioned in a way which shows that there was still some doubt whether neighbouring kinsmen should not take inheritance instead of the latter. These are systems of a very archaic arrangement based on a close tribal community between the members of a kindred. Such a community is not apparent in later legal custom, but there are many signs of a close union between members of the same family. The law of Scania, a province of southern Sweden, shows us a group settled around a grandfather. His sons even when married hold part of the property under him and it is with some difficulty that they and their wives succeed in separating some of the goods acquired by personal work or brought in by marriage from the rest of the household property (Scanian Law, Danish Text i. 5). The same arrangement appears in Lombard law as regards brothers who remain settled in a common house (Edict of Rothari c. 167). Of course, in all such cases, there could be no real inheritance and succession, but merely the stepping in of the next generation into the rights and duties of the representative of an older generation on the latter's demise. In legal terminology it is a case of accretion and not of succession.

The next stage in the development of succession is presented by an arrangement which was common in Germany, viz. by the management of property under the rule of so-called *Ganerbschaft*. *Ganerben* is the same as the Latin *coheredes, comparticipes, consortes*. A capitulary of 818 mentions such communities of heirs holding in common (cf. Boretius Capitularia, i. 282). While the community lasted none of the shareholders could dispose of any part of the property by his single will. Legally and economically all transactions had to proceed from common consent and common resolve. This did not preclude the possibility of any one among the shareholders claiming his own portion, in which case part of the property had to be meted out to him according to fair computation (*swascara*). There was no legal constraint over the shareholders to remain in common: division could be brought about either by common consent or by claims of individuals, and yet the constant occurrence of these settlements of co-heirs shows that as a matter of fact it was more profitable to keep together and not to break up the unit of property by division. The customary union of co-heirs appears in this way as a corrective of the strict legal principle of equal rights between heirs of the same degree. In English practice the joint management of co-heirs is not so fully described, but there can be no doubt that under the older Saxon rule admitting heirs of the same degree to equal rights in succession the interests of economic efficiency were commonly preserved by the carrying on of common husbandry without any realization of the concurrent claims which would have broken up the object of succession. This accounts for the fact that notwithstanding the prevalence among the early English of the rule admitting all the sons or heirs in the same position to equal shares in the inheritance, the organic units of hides, yardlands, &c. are kept up in the course of centuries. In the management of so-called *gavelkind* succession in Kent partition was legally possible and came sometimes to be effected, but there was the customary reaction against it in the shape of keeping up the "yokes" and "sulungs." A trace of the same kind of union between co-heirs appears in the so-called *parage* communities so often mentioned in Domesday Book.

In all these cases the principle of union and joint management is kept up by purely economic means and considerations. The legal possibility of partition is admitted by the side of it. It is interesting to watch two divergent lines of further development springing from this common source; on the one side we see the full realization of individual right resulting in frequent divisions; on the other side we watch the rise of legal restraints on subdivision resulting in the establishment, in respect of certain categories of property, of rules excluding the plurality of heirs for the sake of preserving the unity of the household. The first system is, of course, most easily carried out in countries where individualistic types of husbandry prevail. In Europe it is especially prevalent in the south with its intense cultivation of the arable and its habits of wine and olive growing. We shall not wonder, therefore, that the unrestricted subdivision among heirs is represented most completely by Roman law. Not to speak of the fact that already in the XII. Tables the principal mode of inheritance was considered to be inheritance by will while intestate succession came in as a subsidiary expedient, we have to notice that there is no check on the dispersion of property among heirs of the same degree. The only survival of a régime of family community may be found in the distinction between *heredes sui* (heirs of their own) and *heredes extranei* (outside heirs of the deceased). The first entered by their own right and took possession of property which had belonged to them potentially even during their ancestor's life. The latter drew their claims from their relationship to the deceased and this did not give them a direct hold on the property in question. Apart from that the civil law of ancient Rome favoured complete division and the same principle is represented in all European legislation derived from Roman law or strongly influenced by it. Sometimes, as in the French *Code Civil*, even the wish of the owner cannot alter the course of such succession as no person can make a will depriving any of his children of their legal share.

In full contrast with this mode of succession prevailing in romanized countries we find the nations proceeding from Germanic stock and strongly influenced by feudalism developing two different kinds of restraints on subdivision. In Scandinavian law this point of view is expressed by the Norwegian customs as to Odal. The principal estates of the country, which, according to the law of the Gulathing have descended through five generations in the same family, cannot be dispersed and alienated at pleasure. They are considered as rightly belonging to the kindred with which a historical connexion has been established. In order to keep these estates within the kindred they are to descend chiefly to men: women are admitted to property in them only in exceptional cases. Originally it is only the daughter of a man who has left no sons and the sister of one who has left no children and no brothers that are admitted to take Odal as if they were men. Nieces and first-cousins are admitted in the sense that they have to pass the property to their nearest male heir. They may, in certain eventualities, be bought out by the nearest male relative. A second peculiarity of Odal consists in the right of relations descending from one of the common ancestors to prevent strangers from acquiring Odal estate. Any holder of such an estate who wants to sell it in its entirety or in portion has first to apply to his relatives and they may acquire the estate at the price proposed by a stranger less one-fifth. Even if no relative has taken advantage of this privilege an Odal estate sold to a stranger may be bought back into the family by compulsory redemption if the relatives subsequently find the means and have the wish to resort to such redemption. Odal right does not curtail the claims of the younger sons or of any heirs in a similar position. As a matter of fact, however, customary succession in Norwegian peasant families sets great price on holding the property of the household well together. It is keenly felt that a *gaard* (farm) ought not to be parcelled up into smaller holdings, and in the common case of several heirs succeeding to the farm, they generally make up among themselves who is to remain in charge of the ancestral household: the rest are compensated in money or helped to start on some other estate or perhaps in a cottage by the side of the principal house. In medieval England, France and Germany the same considerations of economic efficiency are felt as regards the keeping up of united holdings, and it may be said that the lower we get in the scale of property the stronger these considerations become. If it is possible, though not perhaps profitable, to divide the property of a large farm, it becomes almost impossible to break-up the smaller units—so-called yardlands and oxgangs. Through being parcelled up into small plots, land loses in value, and, as to cattle, it is impossible to divide one ox or one horse *in specie* without selling them. No wonder that we find practices and customs of united succession arising in direct contradiction with the ancient rule that all heirs of the same degree should be admitted to equal shares. Glanville mentions expressly that the socagers of his time held partly by undivided succession and partly by divided inheritance. The relations of feudalism and serfdom contributed strongly towards creating such individual tenancies. It was certainly in the interest of the lord that his men, whether holding a military fief or an agricultural farm, should not weaken the value of their tenancies by dispersing the one or the other among heirs. But apart from these interests of over-lords there was the evident self-interest of the tenants themselves and therefore the point of view of unification of holdings is by no means confined to servile tenements or to military fiefs. The question whether the successor should be the eldest son or the youngest son is a secondary one. The latter practice was very prevalent all through Europe and produced in England what is termed the Borough English rule. The quaint name has been derived from the contrast in point of succession between the two parts of the borough of Nottingham. The French burgesses transmitted their tenements by primogeniture, while in the case of the English tenants the youngest sons succeeded. A usual explanation of this passage of the holdings to the youngest is found in the fact that the youngest son remains longest in his father's house, while the elder brothers have opportunities of going out into the world at a time when the father is still alive and able to take care of his land. This is well in keeping with the view that customs of united succession arise in connexion with compensation provided for co-heirs waiving their claims in regard to settlement in the original household. The succession of the youngest appears also very characteristic in so far as it illustrates the break up into small tenancies, as the youngest in the family is certainly not a fit representative of hierarchy and authority and could not have been meant to rule anything but his own restricted household.

One more feature of the ancient law of succession has to be noticed in conclusion, viz. the exclusion of women from inheritance in land. There can be no doubt that as regards movable goods women held property and transmitted it on a par with males right from the earliest time. According to Germanic conception personal ornaments and articles of household furniture are specially effected to their use and follow a distinct line of succession from woman to woman (Gerade). Norse law puts women and men on the same footing as to all forms of property equated to "movable money" (Lösöre); but as to land there is a prevalent idea that men should be privileged. Women are admitted to a certain extent, but always placed behind men of equal degree. Frankish and Lombard law originally excluded women from inheritance in land, and this exclusion seems as ancient as the patriarchial system itself, whatever we may think about the position of affairs in prehistoric times when rules of matriarchy were prevalent. A common-sense explanation of one side of this doctrine is tendered by the law of the Thuringians (*Lex Anglorum et Werinorum*, c. 6). It is stated there that inheritance in land goes with the duty of taking revenge for the homicide of relatives and with the power of bearing arms. One of the most potent adversaries of this system of exclusion proved to be the Church. It favoured all through the view that land should be transmitted in the same way as money or chattels. A Frankish formula (Marculf) shows us a father who takes care to endow his daughter with a piece of land according to natural affection in spite of the strict law of his tribe. Such instruments were strongly backed by the Church, and the view that women should be admitted to hold land on certain occasions had made its way in England as early as Anglo-Saxon times.

(P. Vi.)

SUCCESSION DUTY, in the English fiscal system, "a tax placed on the gratuitous acquisition of property which passes on the death of any person, by means of a transfer from one person (called the predecessor) to another person (called the successor)." In order properly to understand the present state of the English law it is necessary to describe shortly the state of affairs prior to the Finance Act 1894—an act which effected a considerable change in the duties payable and in the mode of assessment of those duties.

The principal act which first imposed a succession duty in England was the Succession Duty Act 1853. By that act a duty varying from 1 to 10 % according to the degree of consanguinity between the predecessor and successor was imposed upon every succession which was defined as "every past or future disposition of property by reason whereof any person has or shall become beneficially entitled to any property, or the income thereof, upon the death of any person dying after the time appointed for the commencement of this act, either immediately or after any interval, either certainly or contingently, and either originally or by way of substitutive limitation and every devolution by law of any beneficial interest in property, or the income thereof, upon the death of any person dying after the time appointed for the commencement of this act to any other person in possession or expectancy." The property which is liable to pay the duty is in realty or leasehold estate in the United Kingdom and personalty—not subject to legacy duty—which the beneficiary claims by virtue of English, Scottish or Irish law. Personalty in England bequeathed by a person domiciled abroad is not subject to succession duty. Successions of a husband or a wife, successions where the principal value is under £100, and individual successions under £20, are exempt from duty. Leasehold property and personalty directed to be converted into real estate are liable to succession, not to legacy duty. Special provision is made for the collection of duty in the cases of joint tenants and where the successor is also the predecessor. The duty is a first charge on property, but if the property be parted with before the duty is paid the liability of the successor is transferred to the alienee. It is, therefore, usual in requisitions on title before conveyance, to demand for the protection of the purchaser the production of receipts for succession duty, as such receipts are an effectual protection notwithstanding any suppression or misstatement in the account on the footing of which the duty was assessed or any insufficiency of such assessment. The duty is by this act directed to be assessed as follows: on personal property, if the successor takes a limited estate, the duty is assessed on the principal value of the annuity or yearly income estimated according to the period during which he is entitled to receive the annuity or yearly income, and the duty is payable in four yearly instalments free from interest. If the successor takes absolutely he pays in a lump sum duty on the principal value. On real property the duty is payable in eight half-yearly instalments without interest on the capital value of an annuity equal to the annual value of the property. Various minor changes were made. By the Customs and Inland Revenue Act 1881, personal estates under £300 were exempted. By the Customs and Inland Revenue Act 1888 an additional ½% was charged on successions already paying 1% and an additional 1½% on successions paying more than 1%. By the Customs and Inland Revenue Act 1889 an additional duty of 1% called estate duty was payable on successions over £10,000.

The Finance Acts 1894 and 1909 effected large changes in the duties payable on death (for which see ESTATE DUTY; LEGACY). As regards the succession duties they enacted that payment of the estate duties thereby created should include payment of the additional duties mentioned above. Estates under £1000 (£2000 in the case of widow or child of deceased) are exempted from payment of any succession duties. The succession duty payable under the Succession Duty Act 1853 was in all cases to be calculated according to the principal value of the property, *i.e.* its selling value, and though still payable by instalments interest at 3% is chargeable. The additional succession duties are still payable in cases where the estate duty is not charged, but such cases are of small importance and in practice are not as a rule charged.

United States.—The United States imposed a succession duty by the War Revenue Act of 1898 on all legacies or distributive shares of personal property exceeding $10,000. It is a tax on the privilege of succession. Devises or distributions of land are not affected by it. The rate of duty runs from 75 cents on the $100 to $5 on the $100, if the legacy or share in question does not exceed $25,000. On those of over that value the rate is multiplied 1½ times on estates up to $100,000, twofold on those from $100,000 to $500,000, 2½ times on those from $500,000 to a million, and threefold for those exceeding a million. This statute has been supported as constitutional by the Supreme Court. Many of the states also impose succession duties, or transfer taxes; generally, however, on collateral and remote successions; sometimes progressive, according to the amount of the succession. The state duties generally touch real estate successions as well as those to personal property. If a citizen of state A owns registered bonds of a corporation chartered by state B, which he has put for safe keeping in a deposit vault in state C, his estate may thus have to pay four succession taxes, one to state A, to which he belongs and which, by legal fiction, is the seat of all his personal property; one to state B, for permitting the transfer of the bonds to the legatees on the books of the corporation; one to state C, for allowing them to be removed from the deposit vault for that purpose; and one to the United States.

SUCCINIC ACID, $C_2H_4(CO_2H)_2$. Two acids corresponding to this empirical formula are known—namely ethylene succinic acid, $HO_2C\cdot CH_2\cdot CH_2\cdot CO_2H$ and ethylidene succinic acid $CH_3\cdot CH(CO_2H)_2$.

Ethylene succinic acid occurs in amber, in various resins and lignites, in fossilized wood, in many members of the natural orders of Papaveraceae and Compositae, in unripe grapes, urine and blood. It is also found in the thymus gland of calves and in the spleen of cattle. It may be prepared by the oxidation of fats and of fatty acids by nitric acid, and is also a product of the fermentation of malic and tartaric acids. It is usually obtained by the distillation of amber, or by the fermentation of calcium malate or ammonium tartrate. Synthetically it may be obtained by reducing malic or tartaric acids with hydriodic acid (R. Schmitt, *Ann.*, 1860, 114, p. 106; V. Dessaignes, ibid., 1860, 115, p. 120; by reducing fumaric and maleic acids with sodium amalgam; by heating bromacetic acid with silver to 130° C.; in small quantity by the oxidation of acetic acid with potassium persulphate (C. Moritz and R. Wolffenstein, *Ber.*, 1899, 32, p. 2534); by the hydrolysis of succinonitrile (from ethylene dibromide) $C_2H_4 \rightarrow C_2H_4Br_2 \rightarrow C_2H_4(CN)_2 \rightarrow C_2H_4(CO_2H)_2$; by the hydrolysis of β-cyanpropionic ester; and by the condensation of sodiomalonic ester with monochloracetic ester and hydrolysis of the resulting ethane tricarboxylic ester $(RO_2C)_2CH\cdot CH_2\cdot CO_2R$; this method is applicable to the preparation of substituted succinic acids. It is also produced by the electrolysis of a concentrated solution of potassium ethyl malonate.

It crystallizes in prisms or plates which melt at 185° C. and boil at 235° C. with partial conversion into the anhydride. It is readily soluble in water. Aqueous solutions of the acid are decomposed in sunlight by uranium salts, with evolution of carbon dioxide and the formation of propionic acid. Potassium permanganate, in acid solution, oxidizes it to carbon dioxide and water. The sodium salt on distillation with phosphorus trisulphide gives thiophene. The esters of the acid condense readily with aromatic aldehydes and ketones to form γ-di-substituted itaconic acids and γ-alkylen pyrotartaric acids (H. Stobbe, *Ann.*, 1899, 308, p. 71). γ-Oxyacids are formed when aldehydes are heated with sodium succinate and sodium acetate. Numerous salts of the acid are known, the basic ferric salt being occasionally used in quantitative analysis for the separation of iron from aluminium.

Succinyl chloride, obtained by the action of phosphorus pentachloride on succinic acid, is a colourless liquid which boils at 190° C. In many respects it behaves as though it were dichlorbutyro-lactone,

$C_2H_4{<}\genfrac{}{}{0pt}{}{CCl_2}{CO}{>}O$; *e.g.* on reduction it yields butyro-lactone, and when

condensed with benzene in the presence of aluminium chloride it yields chiefly γ-diphenylbutyro-lactone. *Succinic anhydride*, $C_2H_4(CO)_2O$, is obtained by heating the acid or its sodium salt with acetic anhydride; by the action of acetyl chloride on the barium salt; by distilling a mixture of succinic acid and succinyl chloride, or by heating succinyl chloride with anhydrous oxalic acid. It crystallizes in plates which melt at 120° C., and distils without decomposition. It is slowly dissolved by water with the formation of the acid. It combines readily with the meta-aminophenols to form rhodamines, which are valuable dyestuffs. Heated in a current of ammonia it gives *succinimide*, which is also obtained on heating acid ammonium succinate. It crystallizes in colourless octahedra which melt at 125–126° C., and is easily soluble in water. When warmed with baryta water it yields succinamic acid, $HO_2C\cdot CH_2\cdot CH_2\cdot CONH_2$; and with alcoholic ammonia at 100° C. it gives succinamide. The imino hydrogen atom is easily replaced by metals. Distillation with zinc dust gives pyrrol (*q.v.*). By the action of bromine in alkaline solution it is converted into β-aminopropionic acid. *Succinamide*, $C_2H_4(CONH_2)_2$, best obtained by the action of ammonia on diethyl succinate, crystallizes in needles which melt at 242–243° C., and is soluble in hot water. *Succinonitrile*, $C_2H_4(CN)_2$, is obtained by the action of potassium cyanide on ethylene dibromide or by the electrolysis of a solution of potassium cyanacetate. It is an amorphous solid which melts at 54–55° C. On reduction with sodium in alcoholic solution it yields tetraethylene diamine (putrescein) and pyrollidine.

Methyl succinic acid (pyrotartaric acid), $HO_2C\cdot CH_2\cdot CH(CH_3)\cdot CO_2H$, is formed by the dry distillation of tartaric acid; by heating pyruvic acid with concentrated hydrochloric acid to 180° C.; by the reduction of citraconic and mesaconic acids with sodium amalgam; and by the hydrolysis of β-cyanbutyric acid. It crystallizes in small prisms which melt at 112° C. and are soluble in water. It forms an anhydride when heated. The sodium salt on heating with phosphorus trisulphide yields methylthiophen.

Ethylidene succinic acid or *isosuccinic acid*, $CH_3 \cdot CH(CO_2H)_2$, is produced by the hydrolysis of α-cyanpropionic acid and by the action of methyl iodide on sodio-malonic ester. It crystallizes in prisms which melt at 120° C. (T. Salzer, *Journ. prak. Chem.*, 1898 [2], 57, p. 497), and dissolve in water. It does not yield an anhydride, but when heated loses carbon dioxide and leaves a residue of propionic acid. It may be distinguished from the isomeric ethylene succinic acid by the fact that its sodium salt does not give a precipitate with ferric chloride.

SUCHER, ROSA (1849–), German opera singer, *née* Hasselbeck, was the wife of Josef Sucher (1844–1908), a well-known conductor and composer. They were married in 1876, when she had already had various engagements as a singer and he was conductor at the Leipzig city theatre. Frau Sucher soon became famous for her performances in Wagner's operas, her seasons in London in 1882 and 1892 proving her great capacity both as singer and actress; in 1886 and 1888 she sang at Bayreuth, and in later years she was principally associated with the opera stage in Berlin, retiring in 1903. Her magnificent rendering of the part of Isolde in Wagner's opera is especially remembered.

SUCHET, LOUIS GABRIEL, Duc D'Albufera da Valencia (1770–1826), marshal of France, one of the most brilliant of Napoleon's generals, was the son of a silk manufacturer at Lyons, where he was born on the 2nd of March 1770. He originally intended to follow his father's business; but having in 1792 served as volunteer in the cavalry of the national guard at Lyons, he manifested military abilities which secured his rapid promotion. As *chef de bataillon* he was present at the siege of Toulon in 1793, where he took General O'Hara prisoner. During the Italian campaign of 1796 he was severely wounded at Cerea on the 11th of October. In October 1797 he was appointed to the command of a demi-brigade, and his services, under Joubert in the Tirol in that year, and in Switzerland under Brune in 1797–98, were recognized by his promotion to the rank of general of brigade. He took no part in the Egyptian campaign, but in August was made chief of the staff to Brune, and restored the efficiency and discipline of the army in Italy. In July 1799 he was made general of division and chief of staff to Joubert in Italy, and was in 1800 named by Masséna his second in command. His dexterous resistance to the superior forces of the Austrians with the left wing of Masséna's army, when the right and centre were shut up in Genoa, not only prevented the invasion of France from this direction but contributed to the success of Napoleon's crossing the Alps, which culminated in the battle of Marengo on the 14th of June. He took a prominent part in the Italian campaign till the armistice of Treviso. In the campaigns of 1805 and 1806 he greatly increased his reputation at Austerlitz, Saalfeld, Jena, Pultusk and Ostrolenka. He obtained the title of count on the 19th of March 1808, married Mlle de Saint Joseph, a niece of Joseph Bonaparte's wife, and soon afterwards was ordered to Spain. Here, after taking part in the siege of Saragossa, he was named commander of the army of Aragon and governor of the province, which, by wise and (unlike that of most of the French generals) disinterested administration no less than by his brilliant valour, he in two years brought into complete submission. He annihilated the army of Blake at Maria on the 14th of June 1809, and on the 22nd of April 1810 defeated O'Donnell at Lerida. After being made marshal of France (July 8, 1811) he in 1812 achieved the conquest of Valencia, for which he was rewarded with the title of duc d'Albufera da Valencia (1812). When the tide set against the French Suchet defended his conquests step by step till compelled to retire into France, after which he took part in Soult's defensive campaign. By Louis XVIII. he was on the 4th of June made a peer of France, but, having during the Hundred Days commanded one of Napoleon's armies on the Alpine frontier, he was deprived of his peerage on the 24th of July 1815. He died near Marseilles on the 3rd of January 1826. Suchet wrote *Mémoires* dealing with the Peninsular War, which were left by the marshal in an unfinished condition, and the two volumes and atlas appeared in 1829–1834 under the editorship of his former chief staff officer, Baron St Cyr-Nogués.

See C. H. Barault-Roullon, *Le Maréchal Suchet* (Paris, 1854); Choumara, *Considerations militaires sur les mémoires du Maréchal Suchet* (Paris, 1840), a controversial work on the last events of the Peninsular War, inspired, it is supposed, by Soult; and Lieutenant-General Lamarque's obituary notice in the *Spectateur militaire* (1826). See also bibliography in article Peninsular War.

SU-CHOW. There are in China three cities of this name which deserve mention.

1. Su-chow-Fu, in the province of Kiang-su, formerly one of the largest cities in the world, and in 1907 credited still with a population of 500,000, on the Grand Canal, 55 m. W.N.W. of Shanghai, with which it is connected by railway. The site is practically a cluster of islands to the east of Lake Tai-hu. The walls are about 10 m. in circumference and there are four large suburbs. Its silk manufactures are represented by a greater variety of goods than are produced anywhere else in the empire; and the publication of cheap editions of the Chinese classics is carried to great perfection. There is a Chinese proverb to the effect that to be perfectly happy a man ought to be born in Su-chow, live in Canton and die in Lien-chow. The nine-storeyed pagoda of the northern temple is one of the finest in the country. In 1860 Su-chow was captured by the T'aip'ings, and when in 1863 it was recovered by General Gordon the city was almost a heap of ruins. It has since largely recovered its prosperity, and besides 7000 silk looms has cotton mills and an important trade in rice. Of the original splendour of the place some idea may be gathered from the beautiful plan on a slab of marble preserved since 1247 in the temple of Confucius and reproduced in Yule's *Marco Polo*, vol. i. Su-chow was founded in 484 by Ho-lu-Wang, whose grave is covered by the artificial "Hill of the Tiger" in the vicinity of the town. The literary and poetic designation of Su-chow is Ku-su, from the great tower of Ku-su-tai, built by Ho-lu-Wang. Su-chow was opened to foreign trade by the Japanese treaty of 1895. A Chinese and European school was opened in 1900.

2. Su-chow, formerly Tsiu-tsuan-tsiun, a free city in the province of Kan-suh, in 39° 48′ N., just within the extreme north-west angle of the Great Wall, near the gate of jade. It is the great centre of the rhubarb trade. Completely destroyed in the great Mahommedan or Dungan insurrection (1865–72), it was recovered by the Chinese in 1873 and has been rebuilt.

3. Su-chow, a commercial town situated in the province of Sze-ch'uen at the junction of the Min River with the Yang-tse-Kiang, in 28° 46′ 50″ N. Population (1907) about 50,000.

SUCKLING, SIR JOHN (1609–1642), English poet, was born at Whitton, in the parish of Twickenham, Middlesex, and baptized there on the 10th of February 1609. His father, Sir John Suckling (1569–1627), had been knighted by James I. and was successively master of requests, comptroller of the household and secretary of state. He sat in the first and second parliaments of Charles I.'s reign, and was made a privy councillor. During his career he amassed a considerable fortune, of which the poet became master at the age of eighteen. He was sent to Trinity College, Cambridge, in 1623, and was entered at Gray's Inn in 1627. He was intimate with Thomas Carew, Richard Lovelace, Thomas Nabbes and especially with John Hales and Sir William Davenant, who furnished John Aubrey with information about his friend. In 1628 he left London to travel in France and Italy, returning, however, before the autumn of 1630, when he was knighted. In 1631 he volunteered for the force raised by the marquess of Hamilton to serve under Gustavus Adolphus in Germany. He was back at Whitehall in May 1632; but during his short service he had been present at the battle of Breitenfeld and in many sieges. He was handsome, rich and generous; his happy gift in verse was only one of many accomplishments, but it commended him especially to Charles I. and his queen. He says of himself ("A Sessions of the Poets") that he "prized black eyes or a lucky hit at bowls above all the trophies of wit." He was the best card-player and the best bowler at court. Aubrey says that he invented the game of cribbage, and relates that his sisters came weeping to the bowling green at Piccadilly to dissuade him from play, fearing that he would lose their portions. In 1634 great scandal was caused in his old circle by a beating which he received at the hands of Sir John Digby, a rival suitor for the hand of the daughter of Sir John Willoughby; and it has been suggested that this incident, which is narrated at length in a letter (Nov. 10, 1634) from George Garrard[1] to Strafford, had something to do with his beginning to seek more serious society. In 1635 he retired to his country estates in obedience to the proclamation of the 20th of June 1632 enforced by the Star Chamber[2] against absentee landlordism, and employed his leisure in literary pursuits. In 1637 "A Sessions of the Poets" was circulated in MS., and about the same time he wrote a tract on Socinianism entitled *An Account of Religion by Reason* (pr. 1646).

As a dramatist Suckling is noteworthy as having applied to regular drama the accessories already used in the production of masques. His *Aglaura* (pr. 1638) was produced at his own expense with elaborate scenery. Even the lace on the actors' coats was of real gold and silver. The play, in spite of its felicity of diction, lacks dramatic interest, and the criticism of Richard Flecknoe (*Short Discourse of the English Stage*),[3] that it seemed "full of flowers, but rather stuck in than growing there," is not altogether unjustified. *The Goblins* (1638, pr. 1646) has some reminiscences of *The Tempest*; *Brennoralt, or the Discontented Colonel* (1639, pr. 1646) is a satire on the Scots, who are the Lithuanian rebels of the play; a fourth play, *The Sad One*, was left unfinished owing to the outbreak of the Civil War. Suckling raised a troop of a hundred horse, at a cost of £12,000, and accompanied Charles on the Scottish expedition of 1639. He shared in the earl of Holland's retreat before Duns, and was ridiculed in an amusing ballad (pr. 1656), in *Musarum deliciae*, "on Sir John Suckling's most warlike preparations for the Scottish war."[4] He was elected as member for Bramber for the opening session (1640) of the Long Parliament; and in that winter he drew up a letter addressed to Henry Jermyn, afterwards earl of St Albans, advising the king to disconcert the opposition leaders by making more concessions than they asked for. In May of the following year he was implicated in an attempt to rescue Strafford from the Tower and to bring in French troops to the king's aid. The plot was exposed by the evidence of Colonel George Goring, and Suckling fled beyond the seas. The circumstances of his short exile are obscure. He was certainly in Paris in the summer of 1641. One pamphlet related a story of his elopement with a lady to Spain, where he fell into the hands of the Inquisition. The manner of his death is uncertain, but Aubrey's statement that he put an end to his life by poison in May or June 1642 in fear of poverty is generally accepted.

Suckling's reputation as a poet depends on his minor pieces. They have wit and fancy, and at times exquisite felicity of expression. "Easy, natural Suckling," Millamant's comment in Congreve's *Way of the World* (Act IV., sc. i.) is a just tribute to their spontaneous quality. Among the best known of them are the "Ballade upon a Wedding," on the occasion of the marriage of Roger Boyle, afterwards earl of Orrery, and Lady Margaret Howard, "I prithee, send me back my heart," "Out upon it, I have loved three whole days together," and "Why so pale and wan, fond lover?" from *Aglaura*. "A Sessions of the Poets," describing a meeting of the contemporary versifiers under the presidency of Apollo to decide who should wear the laurel wreath, is the prototype of many later satires.

A collection of Suckling's poems was first published in 1646 as *Fragmenta aurea*, the so-called *Selections* (1836) published by the Rev. Alfred Inigo Suckling, author of the *History and Antiquities of Suffolk* (1846–1848) with *Memoirs* based on original authorities and a portrait after Van Dyck, is really a complete edition of his works, of which W. C. Hazlitt's edition (1874; revised ed., 1892) is little more than a reprint with some additions. *The Poems and Songs of Sir John Suckling*, edited by John Gray and decorated with woodcut border and initials by Charles Ricketts, was artistically printed at the Ballantyne Press in 1896. In 1910 Suckling's works in prose and verse were edited by A. Hamilton Thompson. For anecdotes of Suckling's life see John Aubrey's *Brief Lives* (Clarendon Press ed., ii. 242).

SUCRE, or CHUQUISACA, a city of Bolivia, capital of the department of Chuquisaca and nominal capital of the republic, 46 m. N.E. of Potosí in 19° 2′ 45″ S., 65° 17′ W. Pop. (1900), 20,967; (1906, estimate), 23,416, of whom many are Indians and cholos. The city is in an elevated valley opening southward on the narrow ravine through which flows the Cachimayo, the principal northern tributary of the Pilcomayo. Its elevation, 8839 ft., gives it an exceptionally agreeable climate. There are fertile valleys in the vicinity which provide the city's markets with fruit and vegetables, while the vineyards of Camargo (formerly known as Cinti), in the southern part of the department, supply wine and spirits of excellent quality. The city is laid out regularly, with broad streets, a large central plaza and a public garden, or promenade, called the *prado*. Among its buildings are the cathedral, dating from 1553 and once noted for its wealth; the president's palace and halls of congress, which are no longer occupied as such by the national government; the cabildo, or town-hall; a mint dating from 1572; the courts of justice, and the university of San Xavier, founded in 1624, with faculties of law, medicine and theology. There is a pretty chapel called the "Rotunda," erected in 1852 at the lower end of the *prado* by President Belzú, on the spot where an attempt had been made to assassinate him. Sucre is the seat of the archbishop of La Plata and Charcas, the primate of Bolivia. It is not a commercial town, and its only noteworthy manufacture is the "clay dumplings" which are eaten with potatoes by the inhabitants of the Bolivian uplands. Although the capital of Bolivia, Sucre is one of its most isolated towns because of the difficult character of the roads leading to it. It is reached from the Pacific by way of Challapata, a station on the Antofagasta & Oruro railway.

The Spanish town, according to Velasco, was founded in 1538 by Captain Pedro Angules on the site of an Indian village called Chuquisaca, or Chuquichaca (golden bridge), and was called Charcas and Ciudad de la Plata by the Spaniards, though the natives clung to the original Indian name. It became the capital of the province of Charcas, of the comarca of Chuquisaca, and of the bishopric of La Plata and Charcas, and in time it became the favourite residence and health resort of the rich mine-owners of Potosí. The bishopric dates from 1552 and the archbishopric from 1609. In the latter year was created the Real Audiencia de la Plata y Charcas, a royal court of justice having jurisdiction over Upper Peru and the La Plata provinces of that time. Sucre was the first city of Spanish South America to revolt against Spanish rule—on the 25th of May 1809. In 1840 the name Sucre was adopted in honour of the patriot commander who won the last decisive battle of the war, and then became the first president of Bolivia. The city has suffered much from partisan strife, and the removal of the government to La Paz greatly diminished its importance.

SUCZAWA (Rumanian, *Suceava*), a town in Bukovina, Austria, 50 m. S. of Czernowitz by rail. Pop. (1900), 10,955. It is situated on the river Suczawa, which forms there the boundary between Bukovina and Rumania. One of its two churches, dating from the 14th century, contains the grave of the patron saint of Bukovina. The principal industry is the tanning and leather trade. Not far from Suczawa lies the monastery of Dragomirna, in Byzantine style, built at the beginning of the 17th century. Suczawa is a very old town and was until 1565 the capital of the principality of Moldavia. It was many times besieged by Poles, Hungarians, Tatars and Turks. In 1675 it was besieged by Sobieski, and in 1679 it was plundered by the Turks.

SUDAN (Arabic *Bilad-es-Sudan*, country of the blacks), that region of Africa which stretches, south of the Sahara and Egypt, from Cape Verde on the Atlantic to Massawa on the Red Sea. It is bounded S. (1) by the maritime countries of the west coast of Africa, (2) by the basin of the Congo, and (3) by the equatorial lakes, and E. by the Abyssinian and Galla highlands. The name is often used in Great Britain in a restricted sense to designate only the eastern part of this vast territory, but it is properly applied to the whole area indicated, which corresponds roughly to that portion of negro Africa north of the equator under Mahommedan influence. The terms Nigritia and Negroland, at one time current, referred to the same region.

The Sudan has an ethnological rather than a physical unity, and politically it is divided into a large number of states, all now under the control of European powers. These countries being separately described, brief notice only is required of the Sudan as a whole.

Within the limits assigned it has a length of about 4000 m., extending southwards at some points 1000 m., with a total area of over 2,000,000 sq. m., and a population, approximately, of 40,000,000. Between the arid and sandy northern wastes and the well-watered and arable Sudanese lands there is a transitional zone of level grassy steppes (partly covered with mimosas and acacias) with a mean breadth of about 60 m. The zone lies between 17° and 18° N., but towards the centre reaches as far south as 15° N. Excluding this transitional zone, the Sudan may be described as a moderately elevated region, with extensive open or rolling plains, level plateaus, and abutting at its eastern and western ends on mountainous country. Crystalline rocks, granites, gneisses and schists, of the Central African type, occupy the greater part of the country. Towards the south-east, slates, quartzites and iron-bearing schists occur, but their age is not known. The Congo sandstones do not appear to extend as far north. The Nubian sandstone borders the Libyan desert on the south and south-west, but it is doubtful if this sandstone is of Cretaceous or earlier date.

The Sudan contains the basin of the Senegal and parts of three other hydrographic systems, namely: the Niger, draining southwards to the Atlantic; the central depression of Lake Chad; and the Nile, flowing northwards to the Mediterranean. Lying within the tropics and with an average elevation of not more than 1500 to 2000 ft. above the sea, the climate of the Sudan is hot and in the river valleys very unhealthy. Few parts are suitable for the residence of Europeans. Cut off from North Africa by the Saharan desert, the inhabitants, who belong in the main to the negro family proper, are thought to have received their earliest civilization from the East. Arab influence and the Moslem religion began to be felt in the western Sudan as early as the 9th century and had taken deep root by the end of the 11th. The existence of native Christian states in Nubia hindered for some centuries the spread of Islam in the eastern Sudan, and throughout the country some tribes have remained pagan. It was not until the last quarter of the 19th century that the European nations became the ruling force.

The terms western, central and eastern Sudan are indicative of geographical position merely. The various states are politically divisible into four groups: (1) those west of the Niger; (2) those between the Niger and Lake Chad; (3) those between Lake Chad and the basin of the Nile; (4) those in the upper Nile valley.

The first group includes the native states of Bondu, Futa Jallon, Masina, Mossi and all the tribes within the great bend of the Niger. In the last quarter of the 19th century they fell under the control of France, the region being styled officially the French Sudan. In 1900 this title was abandoned. The greater part of what was the French Sudan is now known as the Upper Senegal and Niger Colony (see SENEGAL, FRENCH WEST AFRICA, &c.).

The second group of Sudanese states is almost entirely within the British protectorate of Northern Nigeria. It includes the sultanate of Sokoto and its dependent emirates of Kano, Bida, Zaria, &c., and the ancient sultanate of Bornu, which, with Adamawa, is partly within the German colony of Cameroon (see NIGERIA and CAMEROON).

The third or central group of Sudanese states is formed of the sultanates of Bagirmi (*q.v.*) with Kanem and Wadai (*q.v.*). Wadai was the last state of the Sudan to come under European influence, its conquest being effected in 1909. This third group is included in French Congo (*q.v.*).

The fourth group consists of the states conquered during the 19th century by the Egyptians and now under the joint control of Great Britain and Egypt. These countries are known collectively as the Anglo-Egyptian Sudan (see below).

For the regions west of Lake Chad the standard historical work is the *Travels* of Dr Heinrich Barth (5 vols., London, 1857–1858). Consult also P. C. Meyer, *Erforschungsgeschichte und Staatenbildungen des Westsudan* (Gotha, 1897), an admirable summary with bibliography and maps; Karl Kumm, *The Sudan* (London, 1907); Lady

Lugard, *A Tropical Dependency* (London, 1905); and the bibliographies given under the various countries named. For sources and history see TIMBUKTU. For the central Sudan the most important work is that of Gustav Nachtigal, *Sahara und Sudan* (3 vols., Berlin 1879–1889). See also Boyd Alexander, *From the Niger to the Nile* (2 vols., London, 1907); Karl Kumm, *From Haussaland to Egypt* (London, 1910). For the eastern Sudan see the bibliographies under the following section. A good general work is P. Paulitschke's *Die Sudânländer* (Freiburg, 1885).

THE ANGLO-EGYPTIAN SUDAN

The region which before the revolt of the Arabized tribes under the Mahdi Mahommed Ahmed in 1881–84 was known as the Egyptian Sudan has, since its reconquest by the Anglo-Egyptian expeditions of 1896–98, been under the joint sovereignty of Great Britain and Egypt. The limits of this condominium differ slightly from those of the Egyptian Sudan of the pre-Mahdi period. It is bounded N. by Egypt (the 22nd parallel of N. lat. being the dividing line), E. by the Red Sea, Eritrea and Abyssinia, S. by the Uganda Protectorate and Belgian Congo, W. by French Congo. North of Darfur is the Libyan Desert, in which the western and northern frontiers meet. Here the boundary is undefined.[1]

Boundaries and Area.

As thus constituted the Anglo-Egyptian Sudan forms a compact territory which, being joined southwards by the Uganda Protectorate, brings the whole of the Nile valley from the equatorial lakes to the Mediterranean under the control of Great Britain. The Anglo-Egyptian Sudan extends north to south about 1200 m. in a direct line, and west to east about 1000 m. also in a direct line. It covers 950,000 sq. m., being about one-fourth the area of Europe. In what follows the term Sudan is used to indicate the Anglo-Egyptian condominium only.

Physical Features.—The Sudan presents many diversified features. It may be divided broadly into two zones. The northern portion, from about 16° N., is practically the south-eastern continuation of the Saharan desert; the southern region is fertile, abundantly watered, and in places densely forested. West of the Nile there is a distinctly marked intermediate zone of steppes. In the southern district, between 5° and 10° N., huge swamps extend on either side of the Nile and along the Bahr-el-Ghazal.

From south to north the Sudan is traversed by the Nile (*q.v.*), and all the great tributaries of that river are either partly or entirely within its borders. The most elevated district is a range of mountains running parallel to the Red Sea. These mountains, which to the south join the Abyssinian highlands, present their steepest face eastward, attaining heights within the Sudan of 4000 to over 7000 ft. Jebel Erba, 7480 ft., and Jebel Soturba, 6889 ft. (both between 21° and 22° N.), the highest peaks, face the Red Sea about 20 m. inland. Westward the mountains slope gradually to the Nile valley, which occupies the greater part of the country and has a general level of from 600 to 1600 ft. In places, as between Suakin and Berber and above Roseires on the Blue Nile, the mountains approach close to the river. Beyond the Nile westward extend vast plains, which in Kordofan and Dar Nuba (between 10° and 15° N.) are broken by hills reaching 2000 ft. Farther west, in Darfur, the country is more elevated, the Jebel Marra range being from 5000 to 6000 ft. high. In the south-west, beyond the valley of the Bahr-el-Ghazal, the country gradually rises to a ridge of hills, perhaps 2000 ft. high, which running south-east and north-west form the water-parting between the Nile and the Congo.

Apart from the Nile system, fully described elsewhere, the Sudan has two other rivers, the Gash and the Baraka. These are intermittent streams rising in the eastern chain of mountains in Eritrea and flowing in a general northerly direction. The Gash enters the Sudan near Kassala and north of that town turns west towards the Atbara, but its waters are dissipated before that river is reached. The Gash nevertheless fertilizes a considerable tract of country. The Khor Baraka lies east of the Gash. It flows towards the Red Sea in the neighbourhood of Trinkitat (some 50 m. south of Suakin), but about 30 m. from the coast forms an inland delta. Except in seasons of great rain its waters do not reach the sea.

The Coast Region.—The coast extends along the Red Sea north to south from 22° N. to 18° N., a distance following the indentations of the shore of over 400 m. These indentations are numerous but not deep, the general trend of the coast being S.S.E. The most prominent headland is Ras Rawaya (21° N.) which forms the northern shore of Dokhana Bay. There are few good harbours, Port Sudan and Suakin being the chief ports. South of Suakin is the shallow bay of Trinkitat. A large number of small islands lie off the coast. A belt of sandy land covered with low scrub stretches inland ten to twenty miles, and is traversed by khors (generally dry) with ill-defined shifting channels. Beyond this plain rise the mountain ranges already mentioned. Their seaward slopes often bear a considerable amount of vegetation.

The Desert Zone.—The greater part of the region between the coast and the Nile is known as the Nubian Desert. It is a rugged, rocky, barren waste, scored with khors or wadis, along whose beds there is scanty vegetation. The desert character of the country increases as the river is neared, but along either bank of the Nile is a narrow strip of cultivable land. West of the Nile there are a few oases—those of Selima, Zaghawa and El Kab—but this district, part of the Libyan Desert, is even more desolate than the Nubian Desert.

The Intermediate Zone and the Fertile Districts.—East of the Nile the region of absolute desert ceases about the point of the Atbara confluence. The country enclosed by the Nile, the Atbara and the Blue Nile, the so-called Island of Meroë, consists of very fertile soil, and along the eastern frontier, by the upper courses of the rivers named, is a district of rich land alternating with prairies and open forests. The fork between the White and Blue Niles, the Gezira, is also fertile land. South of the Gezira is Sennar, a well-watered country of arable and grazing land.

West of the Nile the desert zone extends farther south than on the east, and Kordofan, which comes between the desert and the plains of the Bahr-el-Ghazal, is largely barren and steppe land. South of 10° N. there is everywhere abundance of water. Darfur is mainly open, steppe-like country with extensive tracts of cultivable land and a central mountain massif, the Jebel Marra (see SENNAR KORDOFAN, DARFUR).

Climate.—The country lies wholly within the tropics, and as the greater part of it is far removed from the ocean and less than 1500 ft. above the sea it is extremely hot. The heat is greatest in the central regions, least in the desert zone, where the difference between summer and winter is marked. Even in winter, however, the day temperatures are high. Of this region the Arabs say "the soil is like fire and the wind like a flame." Nevertheless, the dryness of the air renders the climate healthy. The steppe countries, Kordofan and Darfur, are also healthy except after the autumn rains. At Khartum, centrally situated, the minimum temperature is about 40° F., the maximum 113°, the mean annual temperature being 80°. January is the coldest and June the hottest month. Violent sand-storms are frequent from June to August. Four rain zones may be distinguished. The northern (desert) region is one of little or no rain. There are perhaps a few rainy days in winter and an occasional storm in the summer. In the central belt, where "the rainy season" is from mid-June to September, there are some 10 in. of rain during the year. The number of days on which rain falls rarely exceeds, however, fifteen. The rainfall increases to about 20 in. per annum in the eastern and south-eastern regions. In the swamp district and throughout the Bahr-el-Ghazal heavy rains (40 in. or more a year) are experienced. The season of heaviest rain is from April to September. In the maritime district there are occasional heavy rains between August and January. In the sudd region thunderstorms are frequent. Here the temperature averages about 85° F., the air is always damp and fever is endemic.

Flora.—In the deserts north of Khartum vegetation is almost confined to stunted mimosa and, in the less arid districts, scanty herbage. Between the desert and the cultivated Nile lands is an open growth of samr, hashab (*Acacia verek*) and other acacia trees. Between Khartum and 12° N. forest belts line the banks of the rivers and khors, in which the most noteworthy tree is the sant or sunt (*Acacia arabica*). Farther from the rivers are open woods of heglig (*Balanites aegyptiaca*), hashab, &c., and dense thickets of laot (*Acacia nubica*) and kittr (*Acacia mellifera*). These open woods cover a considerable part of Kordofan, the hashab and talh trees being the chief producers of gum arabic. South of 12° N. the forest lands of the White Nile as far south as the sudd region are of similar character to that described. On the Blue Nile the forest trees alter, the most abundant being the babanus (Sudan ebony) and the silag (*Anogeissus leiocarpus*), while gigantic baobabs, called tebeldi in the Sudan, and tarfa (*Sterculia cinerea*) are numerous. In southern Kordofan and in the higher parts of the Bahr-el-Ghazal the silag and ebony are also common, as well as African mahogany (homraya, *Khaya senegalensis*) and other timber trees. In the Ghazal province also are many rubber-producing lianas, among them the *Landolphia owariensis*. There are also forest regions in the Bahr-el-Jebel, in the Mongalla mudiria and along the Abyssinian-Eritrean frontier. East of the Bahr-el-Jebel and north of the Bahr-el-Ghazal are vast prairies covered with tall coarse grass. Cotton is indigenous in the valley of the Blue Nile, and in some districts bamboos are plentiful. The castor-oil plant grows in almost every province. (See also § *Agriculture*, and, for the vegetation of the swamp region, NILE.)

Fauna.—Wild animals and birds are numerous. Elephants are abundant in the Bahr-el-Ghazal and Bahr-el-Jebel forests, and are found in fewer numbers in the upper valley of the Blue Nile.

[1] It was supposed to be indicated by the line which, according to the Turkish firman of 1841, describes a semicircle from the Siwa Oasis to Wadai, approaching the Nile between the Second and Third Cataracts. This line is disregarded by the Sudan government.

The hippopotamus and crocodile abound in the swamp regions, which also shelter many kinds of water-fowl. The lion, leopard, giraffe and various kinds of antelope are found in the prairies and in the open woods. In the forests are numerous bright-plumaged birds and many species of monkeys, mostly ground monkeys—the trees being too prickly for climbing. Snakes are also plentiful, many poisonous kinds being found. In the steppe regions of Kordofan, Darfur, &c., and in the Nubian Desert ostriches are fairly plentiful. Insect life is very abundant, especially south of 12° N., the northern limit of the tsetse fly. The chief pests are mosquitoes, termites and the serut, a brown fly about the size of a wasp, with a sharp stab, which chiefly attacks cattle. Locusts are less common, but, especially in the eastern districts, occasionally cause great destruction. For domestic animals see § *Agriculture.*

Inhabitants.—The population, always sparse in the desert and steppe regions, was never dense even in the more fertile southern districts. During the Mahdia the country suffered severely from war and disease. Excluding Darfur the population before the Mahdist rule was estimated at 8,500,000. In 1905 an estimate made by the Sudan government put the population at 1,853,000 only, including 11,000 foreigners, of whom 2800 were Europeans. Since that year there has been a considerable natural increase and in 1910 the population was officially estimated at 2,400,000. There has also been a slight immigration of Abyssinians, Egyptians, Syrians and Europeans—the last named chiefly Greeks.

The term "Bilad-es-Sudan" ("country of the blacks") is not altogether applicable to the Anglo-Egyptian condominium, the northern portion being occupied by Hamitic and Semitic tribes, chiefly nomads, and classed as Arabs. In the Nile valley north of Khartum the inhabitants are of very mixed origin. This applies particularly to the so-called Nubians who inhabit the Dongola mudiria (see NUBIA). Elsewhere the inhabitants north of 12° N. are of mixed Arab descent. In the Nubian Desert the chief tribes are the Ababda and Bisharin, the last named grazing their camels in the mountainous districts towards the Red Sea. In the region south of Berber and Suakin are the Hadendoa. The Jaalin, Hassania and Shukria inhabit the country between the Atbara and Blue Nile; the Hassania and Hassanat are found chiefly in the Gezira. The Kabbabish occupy the desert country north of Kordofan, which is the home of the Baggara tribes. In Darfur the inhabitants are of mixed Arab and negro blood.

Of negro Nilotic tribes there are three or four main divisions. The Shilluks occupy the country along the west side of the Nile northward from about Lake No. The country east of the Nile is divided between the Bari, Nuer and Dinka tribes. The Dinkas are also widely spread over the Bahr-el-Ghazal province. South of Kordofan and west of the Shilluk territory are the Nubas, apparently the original stock of the Nubians. In the south-west of the Bahr-el-Ghazal are the Bongos and other tribes, and along the Nile-Congo water-parting are the A-Zande or Niam-Niam, a comparatively light-coloured race. (All the tribes mentioned are separately noticed.)

Social Conditions.—In contrast with the Egyptians, a most industrious race, the Sudanese tribes, both Arab and negro, are as a general rule indolent. Where wants are few and simple, where houses need not be built nor clothes worn to keep out the cold, there is little stimulus to exertion. Many Arabs "clothed in rags, with only a mat for a house, prefer to lead the life of the free-born sons of the desert, no matter how large their herds or how numerous their followings" (*Egypt*, No. 1 [1904], p. 147). Following the establishment of British control slave-raiding and the slave trade were stopped, but domestic slavery continues. A genuine desire for education is manifest among the Arabic-speaking peoples and slow but distinct moral improvement is visible among them. Among the riverain "Arabs" some were found to supply labour for public works, and with the money thus obtained cattle were bought and farms started. The Dongolese are the keenest traders in the country. The Arab tribes are all Mahommedans, credulous and singularly liable to fits of religious excitement. Most of the negro tribes are pagan, but some of them who live in the northern regions have embraced Islam.

Divisions and Chief Towns.—Darfur is under native rule. The rest of the Sudan is divided into mudirias (provinces) and these are subdivided into mamuria. The mudirias are Halfa, Red Sea, Dongola and Berber in the north (these include practically all the region known as Nubia); Khartum, Blue Nile and White Nile in the centre; Kassala and Sennar in the east; Kordofan in the west; and Bahr-el-Ghazal, Upper Nile (formerly Fashoda) and Mongalla in the south. The mudirias vary considerably in size.

The capital, Khartum (*q.v.*), pop. with suburbs about 70,000, is built in the fork formed by the junction of the White and Blue Niles. Opposite Khartum, on the west bank of the White Nile, is Omdurman (*q.v.*), pop. about 43,000, the capital of the Sudan during the Mahdia. On the Nile north of Khartum at the towns of Berber, Abu Hamed, Merawi (Merowe), Dongola and Wadi Halfa. On the Red Sea are Port Sudan and Suakin. Kassala is on the river Gash east of the Atbara and near the Eritrean frontier. (These towns are separately noticed.) On the Blue Nile are Kamlin, Sennar, Wad Medani (*q.v.*), pop. about 20,000, a thriving business centre and capital of the Blue Nile mudiria, and Roseires, which marks the limit of navigability by steamers of the river. Gallabat is a town in the Kassala mudiria close to the Abyssinian frontier, and Gedaref lies between the Blue Nile and Atbara a little north of 14° N. El Obeid, the chief town of Kordofan, is 230 m. south-west by south of Khartum. Duiem, capital of the White Nile mudiria, is the river port for Kordofan. El Fasher, the capital of Darfur, is 500 m. W.S.W. of Khartum. All the towns named, except Roseires, are situated north of 13° N. In the south of the Sudan there are no towns properly so called. The native villages are composed of straw or palm huts; the places occupied by Europeans or Egyptians are merely "posts" where the administrative business of the district is carried on. Fashoda (*q.v.*), renamed Kodok, is the headquarters of the Upper Nile mudiria.

Communications.—North of Khartum the chief means of communication is by railway; south of that city by steamer. There are two trunk railways, one connecting the Sudan with Egypt, the other affording access to the Red Sea. The first line runs from the Nile at Wadi Halfa across the desert in a direct line to Abu Hamed, and from that point follows more or less closely the right (east) bank of the Nile to Khartum. At Khartum the Blue Nile is bridged and the railway is continued south through the Gezira to Sennar. Thence it turns west, crosses the White Nile near Abba Island, and is continued to El Obeid. The length of the line from Halfa to Khartum is 575 m.; from Khartum to Obeid 350 m. The railway from the Nile to the Red Sea starts from the Halfa-Khartum line at Atbara Junction, a mile north of the Atbara confluence. It runs somewhat south of the Berber-Suakin caravan route. At Sallom, 278 m. from Atbara Junction, the line divides, one branch going north to Port Sudan, the other south to Suakin. The total distance to Port Sudan from Khartum is 493 m., the line to Suakin being 4 m. longer. Besides these main lines a railway, 138 m. long, runs from Abu Hamed on the right bank of the Nile to Kareima (opposite Merawi) in the Dongola mudiria below the Fourth Cataract. (The railway which started from Halfa and followed the right bank of the Nile to Kerma, 201 m. from Halfa, was abandoned in 1903.) The railways are owned and worked by the state.

In connexion with the Khartum-Halfa railway steamers ply on the Nile between Halfa and Shellal (Assuan) where the railway from Alexandria ends. The distance by rail and steamer between Khartum and Alexandria is about 1490 m. Steamers run on the Nile between Kerma and Kareima, and above Khartum the government maintains a regular service of steamers as far south as Gondokoro in the Uganda Protectorate. During flood season there is also a steamship service on the Blue Nile. Powerful dredgers and sudd-cutting machines are used to keep open communications in the upper Nile and Bahr-el-Ghazal.

The ancient caravan routes Korosko-Abu Hamed and Berber-Suakin have been superseded by the railways, but elsewhere wells and rest-houses are maintained along the main routes between the towns and the Nile. On some of these roads a motor car service is maintained.

From Port Sudan and Suakin there is a regular steamship service to Europe via the Suez Canal. There are also services to Alexandria, the Red Sea ports of Arabia, Aden and India.

There is an extensive telegraphic system. Khartum is connected by land lines with Egypt and Uganda, thus affording direct telegraphic connexion between Alexandria and Mombasa (2500 m.). From Khartum other lines go to Kassala and the Red Sea ports. In some places the telegraph wires are placed 16 ft. 6 in. above the ground to protect them from damage by giraffes.

Agriculture and other Industries.—North of Khartum agricultural land is confined to a narrow strip on either side of the Nile and to the few oases in the Libyan Desert. In the Gezira and in the plains of Gedaref between the Blue Nile and the Atbara there are wide areas of arable land, as also in the neighbourhood of Kassala along the banks of the Gash. In Kordofan and Darfur cultivation is confined to the khors or valleys. The chief grain crop is durra, the staple food of the Sudanese. Two crops are obtained yearly in several districts. On lands near the rivers the durra is sown after the flood has gone down and also at the beginning of the rainy season. Considerable quantities of wheat and barley are also grown. Other foodstuffs raised are lentils, beans, onions and melons. The date-palm is cultivated along the Nile valley below Khartum, especially on the west bank in the Dongola mudiria and in the neighbouring oases. Dates are also a staple product in Darfur and Kordofan. Ground-nuts and sesame are grown in large quantities for the oil they yield, and cotton of quality equal to that grown in the Delta is produced. The Sudan was indeed the original home of Egyptian cotton.

For watering the land by the river banks sakias (water-wheels) are used, oxen being employed to turn them. There are also a few irrigation canals. In 1910, apart from the date plantations, about 1,500,000 acres were under cultivation. In 1910 a system of basin irrigation was begun in Dongola mudiria.

Gum and rubber are the chief forest products. The gum is obtained from eastern Kordofan and in the forests in the upper valley of the Blue Nile, the best gum coming from Kordofan. It is of two kinds, *hashab* (white) and *talh* (red), the white being the most valuable. Rubber is obtained from the Bahr-el-Ghazal—where there are Para and Ceara rubber plantations—and in the Sobat district. The wood of the sunt tree is used largely for boat-building and for fuel, and the mahogany tree yields excellent timber. Fibre is made from several trees and plants. Elephants are hunted for the sake of their ivory. The wealth of the Arab tribes consists largely in their herds of camels, horses and cattle. They also keep ostrich farms, the feathers being of good quality. The Dongola breed of horses is noted for its strength and hardness. The camels are bred in the desert north of Berber, between the Nile and Red Sea, in southern Dongola, in the Hadendoa country and in northern Kordofan. The Sudanese camel is lighter, faster and better bred than the camel of Egypt. The camel, horse and ostrich are not found south of Kordofan and Sennar. The negro tribes living south of those countries possess large herds of cattle, sheep and goats. The cattle are generally small and the sheep yield little wool. The Arabs use the cattle as draught-animals as well as for their milk and flesh; the negro tribes as a rule do not eat their oxen. Fowls are plentiful, but of poor quality. Donkeys are much used in the central regions; they make excellent transport animals.

Mineral Wealth.—In ancient times Nubia, *i.e.* the region between the Red Sea and the Nile south of Egypt and north of the Suakin-Berber line, was worked for gold. Ruins of an extensive gold-mine exist near Jebel Erba at a short distance from the sea. In 1905 gold mining recommenced in Nubia, in the district of Um Nabardi, which is in the desert, about midway between Wadi Halfa and Abu Hamed. A light railway, 30 m. long, opened in June 1905, connects Um Nabardi with the government railway system. The producing stage was reached in 1908, and between September 1908 and August 1909 the mines yielded 4500 oz. of gold. Small quantities of gold-dust are obtained from Kordofan, and gold is found in the Beni-Shangul country south-west of Sennar, but this region is within the Abyssinian frontier (agreement of the 15th of May 1902). There is lignite in the Dongola mudiria and iron ore is found in Darfur, southern Kordofan and in the Bahr-el-Ghazal. In the last-named mudiria iron is worked by the natives. The district of Hofrat-el-Nahas (the copper mine) is rich in copper, the mines having been worked intermittently from remote times.

Trade.—The chief products of the Sudan for export are gum, ivory, ostrich feathers, dates and rubber. Cotton, cotton-seed and grain (durra, wheat, barley) sesame, livestock, hides and skins, beeswax, mother-of-pearl, senna and gold are also exported. Before the opening (1906) of the railway to the Red Sea the trade was chiefly with Egypt via the Nile, and the great cost of carriage hindered its development. Since the completion of the railway named goods can be put on the world's markets at a much cheaper rate. Besides the Egyptian and Red Sea routes there is considerable trade between the eastern mudirias and Abyssinia and Eritrea, and also some trade south and west with Uganda and the Congo countries. The Red Sea ports trade largely with Arabia and engage in pearl fishery. The principal imports are cotton goods, food-stuffs (flour, rice, sugar, provisions), timber, tobacco, spirits (in large quantities), iron and machinery, candles, cement and perfumery. The value of the trade, which during the Mahdist rule (1884–1898) was a few thousands only, had increased in 1905 to over £1,500,000. In 1908 the exports of Sudan produce were valued at £E515,000[1]; the total imports at £E1,892,000.

Government.—The administration is based on the provisions of a convention signed on the 19th of January 1899 between the British and Egyptian governments. The authority of the sovereign powers is represented by a governor-general appointed by Egypt on the recommendation of Great Britain. In 1910 a council consisting of four *ex officio* members and from two to four non-official nominated members was created to advise the governor-general in the exercise of his executive and legislative functions. Subject to the power of veto retained by the governor-general all questions are decided by a majority of the council. Each of the mudirias into which the country is divided is presided over by a mudir (governor) responsible to the central government at Khartum. The governor-general, the chiefs of the various departments of state and the mudirs are all Europeans, the majority being British military officers. The minor officials are nearly all Egyptians or Sudanese. Revenue is derived as to about 60% from the customs and revenue-earning departments (*i.e.* steamers, railways, posts and telegraphs), and as to the rest from taxes on land, date-trees and animals, from royalties on gum, ivory and ostrich feathers, from licences to sell spirits, carry arms, &c., and from fees paid for the shooting of game. Expenditure is largely on public works, education, justice and the army. Financial affairs are managed from Khartum, but control over expenditure is exercised by the Egyptian financial department. The revenue, which in 1898 was £E35,000, for the first time exceeded a million in 1909, when the amount realized was £E1,040,200. The expenditure in 1909 was £E1,153,000. Financially the government had been, up to 1910, largely dependent upon Egypt. In the years 1901–1909 £E4,378,000 was advanced from Cairo for public works in the Sudan; in the same period a further sum of about £E2,750,000 had been found by Egypt to meet annual deficits in the Sudan budgets (see *Egypt*, No. 1 [1910], pp. 5-6).

Justice.—The Sudan judicial codes, based in part on those of India and in part on the principles of English law and of Egyptian commercial law, provide for the recognition of "customary law" so far as applicable and "not repugnant to good conscience." In each mudiria criminal justice is administered by a court, consisting of the mudir (or a judge) and two magistrates, which has general competence. The magistrates are members of the administrative staff, who try minor cases without the help of the mudir (or judge). The governor-general possesses revising powers in all cases. Civil cases of importance are heard by a judge (or where no judge is available by the mudir or his representative); minor civil cases are tried by magistrates. From the decision of the judges an appeal lies to the legal secretary of the government, in his capacity of judicial commissioner. Jurisdiction in all legal matters as regards personal status of Mahommedans is administered by a grand cadi and a staff of subordinate cadis. The police force of each mudiria is independently organized under the control of the mudirs.

Education.—Education is in charge of the department of public instruction. Elementary education, the medium of instruction being Arabic, is given in *kuttabs* or village schools. There are primary schools in the chief towns where English, Arabic, mathematics, and in some cases land-measuring is taught. There are also government industrial workshops, and a few schools for girls. The Gordon College at Khartum trains teachers and judges in the Mahommedan courts and has annexed to it a secondary school. The college also contains the Wellcome laboratories for scientific research. Among the pagan negro tribes Protestant and Roman Catholic missions are established. These missions carry on educational work, special attention being given to industrial training.

Defence.—The defence of the country is entrusted to the Egyptian army, of which several regiments are stationed in the Sudan. The governor-general is sirdar (commander-in-chief) of the army. A small force of British troops is also stationed in the Sudan—chiefly at Khartum. They are under the command of the governor-general in virtue of an arrangement made in 1905, having previously been part of the Egyptian command.

Archaeology.—Archaeological study in the Sudan was retarded for many years by political conditions. The work which had been begun by Cailliaud, Champollion, Lepsius and others was interrupted by the rise of the Mahdist power; and with the frontiers of Egypt itself menaced by dervishes, the country south of Aswan (Assuan) was necessarily closed to the student of antiquity. Even after the dervishes had been overthrown at the battle of Omdurman (1898) it was some time before archaeologists awoke to a sense of the historical importance of the regions thus made accessible to them. Dr Wallis Budge visited several of the far southern sites and made some tentative excavations, but no extensive explorations were undertaken until an unexpected event produced a sudden outburst of activity. This was the resolution adopted by the Egyptian government to extend the great reservoir at the First Cataract by raising the height of the Aswan dam. As a result of this measure all sites bordering the river banks from Aswan to Abu Simbel were threatened with inundation and the scientific world took alarm. A large sum of money was assigned by the government, partly for the preservation of the visible temples in the area to be submerged, partly for an official expedition under the charge of Dr G. A. Reisner which was to search for all remains of antiquity hidden beneath the ground. At the same time the university of Pennsylvania despatched the Eckley B. Coxe, jun., expedition, which devoted its attention to the southern half of Lower Nubia from Halfa to Korosko, while the government excavators explored from Korosko to Aswan. Thus in the five years 1907–1911 inclusive an immense mass of new material was acquired which throws a flood of light on the archaeology at once of Egypt and the Sudan. For it must be clearly appreciated that though all except the southern twenty miles of Lower Nubia has been attached for purposes of administration of Egypt proper, yet this political boundary is purely artificial. The natural geographical and ethnical southern frontier of Egypt is the First Cataract; Egyptian scribes of the Old Empire recognized this truth no less clearly than Diocletian, and Juvenal anticipates the verdict of every modern observer when he describes the "porta Syenes" as the gate of Africa. It is the more necessary to emphasize this fact as the present article must unavoidably be concerned principally with the most northern regions of the country of the Blacks—for since the days of Lepsius there has been little new investigation south of Halfa. The hasty reconnaissances of Dr Wallis Budge, Professor A. H. Sayce, Mr Somers Clarke and Professor J. Garstang must be followed by more thorough and intensive study before it can be possible to write in more than very general terms of anything but the well-known monuments left by Egyptian kings whose history is already tolerably familiar from other sources. The inscriptions of these kings and their officials have been collected by Professor J. H. Breasted and some account of the temples and fortresses from Halfa to Khartum will be found in the following section, *Ancient Monuments south of Halfa*, while the history of the early and medieval Christian kingdoms is outlined in the articles Ethiopia and Dongola. The central and southern Sudan is therefore almost a virgin field for the archaeologist, but the exploration of Lower Nubia has made it possible to write a tentative preface to the new chapters still unrevealed.

The Sudan was well named by the medieval Arab historians, for it is primarily and above all the country of the *black* races, of those Nilotic negroes whose birthplace may be supposed to have been near the Great Lakes. But upon this aboriginal stock were grafted in very early times fresh shoots of more vigorous and intellectual races coming probably from the East (cf. Africa: *Ethnology*). Lower Nubia was one of the crucibles in which several times was formed a mixed nation which defied or actually dominated Egypt. There is some scientific ground for dating the earliest example of such a fusion to the exact period of the Egyptian Old Empire. It is certain in any case that the process was constantly repeated at different dates and in different parts of the country from Aswan to Axum, and to the stimulation which resulted from it must be ascribed the principal political and intellectual movements of the Sudanese nations. Thus the Ethiopians who usurped the crown of the Pharaohs from 740–660 B.C. were of a mixed stock akin to the modern Barabra; the northern Nubians who successfully defied the Roman emperors were under the lordship of the Blemyes (Blemmyes), an East African tribe, and the empire of the Candace dynasty, no less than the Christian kingdoms which succeeded it, included many heterogeneous racial elements (see also Nubia). The real history of the Sudan will therefore be concerned with the evolution of what may be called East African or East Central African civilizations.

Up to the present, however, this aspect has been obscured, for until 1907 scholars had little opportunity of studying ancient Ethiopia except as a colonial extension of Egypt. From the purely Egyptological standpoint there is much of value to be learned from the Sudan. The Egyptian penetration of the country began, according to the evidence of inscriptions, as early as the Old Empire. Under the XIIth Dynasty colonies were planted and fortresses established down to the Batn-el-Hagar. During the XVIIIth Dynasty the political subjugation was completed and the newly won territories were studded with cities and temples as far south as the Fourth Cataract. Some two hundred years later the priests of Amen (Ammon), flying from Thebes, founded a quasi-Egyptian capital at Napata. But after this date Egypt played no part in the evolution of Ethiopia. Politically moribund, it succumbed to the attacks of its virile southern neighbours, who, having emerged from foreign tutelage, developed according to the natural laws of their own genius and environment. The history of Ethiopia therefore as an independent civilization may be said to date from the 8th century B.C., though future researches may be able to carry its infant origins to a remoter past.

Of the thousand years or more of effective Egyptian occupation many monuments exist, but on a broad general view it must be pronounced that they owe their fame more to the accident of survival than to any special intrinsic value. For excepting Philae, which belongs as much to Egypt as to Ethiopia, Abu Simbel is the only temple which can be ranked among first rate products of Egyptian genius. The other temples, attractive as they are, possess rather a local than a universal interest. Similarly while the exploration of the Egyptian colonies south of the First Cataract has added many details to our knowledge of political history, of local cults and provincial organization, yet with one exception it has not affected the known outlines of the history of civilization. This exception is the discovery made by Dr G. A. Reisner that the archaic culture first detected at Nagada and Abydos and then at many points as far north as Giza extended southwards into Nubia at least as far as Gerf Husein. This was wholly unexpected, and if, as seems probable, the evidence stands the test of criticism, it is a new historical fact of great importance. The government expedition found traces between Aswan and Korosko of all the principal periods from this early date down to the Christian era. The specimens obtained are kept in a separate room of the Cairo Museum, where they form a collection of great value.

The work of the Pennsylvanian expedition, however, while adding only a few details to the archaeology of the Egyptian periods, has opened a new chapter in the history of the African races. No records indeed were discovered of the founders of the first great Ethiopian kingdom from Piankhi to Tirhakah, nor has any fresh light been thrown upon the relations which that remarkable king Ergamenes maintained with the Egyptian Ptolemies. But the exploration of sites in the southern half of Lower Nubia has revealed the existence of a wholly unsuspected independent civilization which grew up during the first six centuries after Christ. The history of the succeeding periods, moreover, has been partially recovered and the study of architecture enriched by the excavation of numerous churches dating from the time of Justinian, when Nubia was first Christianized, down to the late medieval period when Christianity was extirpated by Mahommedanism.

The civilization of the first six centuries A.D. may be called "Romano-Nubian," a term which indicates its date and suggests something of its character. It is the product of a people living on the borders of the Roman Empire who inherited much of the Hellenistic tradition in minor arts but combined it with a remarkable power of independent origination. The sites on which it has been observed range from Dakka to Halfa, that is to say within the precise limits which late Latin and Greek writers assign to the Blemyes, and there is good reason to identify the people that evolved it with this hitherto almost unknown barbarian nation. Apart from this, however, the greatest value of the new discoveries will consist in the fact that they may lay the foundations for a new documentary record of past ages. For the graves yielded not only new types of statues, bronzes, ivory carvings and painted pottery—all of the highest artistic value—but also a large number of stone stelae inscribed with funerary formulae in the Meroitic script.

In the course of sixty years the small collection of Meroitic inscriptions made by Lepsius had not been enlarged and no progress had been made towards decipherment. But the cemeteries of Shablul and Karanog alone yielded 170 inscriptions on stone, besides some inscribed ostraka. This mass of material brought the task of decipherment within the range of possibility, and even without any bilingual record to assist him, Mr F. Ll. Griffith rapidly succeeded in the first stages of translation. As further explorations bring more inscriptions to light the records of Ethiopia will gradually be placed on a firm documentary basis and the names and achievements of its greatest monarchs will take their place on the roll of history.

Ancient Monuments south of Halfa.—Ruins of pyramids, temples, churches and other monuments are found along both banks of the Nile almost as far south as the Fourth Cataract, and again in the "Island of Meroë." In the following list the ruins are named as met with on the journey south from Wadi Halfa. Opposite that town on the east bank are the remains of Bohon, where was found the stele, now at Florence, commemorating the conquest of the region by Senwosri (Usertesen) I. of Egypt (*c.* 2750 B.C.). Forty-three miles farther south are the ruins of the twin fortresses of Kumma and Semna. Here the Nile narrows and passes the Semna cataract, and graven on the rocks are ancient records of "high Nile." At Amara, some 80 m. above Semna, are the ruins of a temple with Meroitic hieroglyphics. At Sai Island, 130 m. above Halfa, are remains of a town and of a Christian church. Thirteen miles south of Sai at Soleb are the ruins of a fine temple commemorating Amenophis (Amenhotep) III. (*c.* 1414 B.C.) to whose queen Taia was dedicated a temple at Sedeinga, a few miles to the north. At Sesebi, 40 m. higher up the Nile, is a temple of the heretic king Akhenaton re-worked by Seti I. (*c.* 1327 B.C.). Opposite Hannek at the Third Cataract on Tombos Island are extensive ancient granite quarries, in one of which lies an unfinished colossus. On the east side of the river near Kerma are the remains of an Egyptian city. Argo Island, a short distance higher up, abounds in ruins, and those at Old Dongola, 320 m. from Halfa, afford evidence of the town having been of considerable size during the time of the Christian kingdom of Dongola. From Old Dongola to Merawi (a distance of 100 m. by the river) are numerous ruins of monasteries, churches and fortresses of the Christian era in Nubia—notably at Jebel Deka and Magal. In the immediate neighbourhood of Jebel Barkal (the "holy mountain" of the ancient Egyptians), a flat-topped hill which rises abruptly from the desert on the right bank of the Nile a mile or two above the existing village of Merawi (Merowe), are many pyramids and six temples, the pyramids having a height of from 35 to 60 ft. Pyramids are also found at Zuma and Kurru on the right bank, and at Tangassi on the left bank of the river, these places being about 20 m. below Merawi. That village is identified by some archaeologists with the ancient Napata, which is known to have been situated near the "holy mountain." On the left bank of the Nile opposite Merawi are the pyramids of Nuri, and a few miles distant in the Wadi Ghazal are the ruins of a great Christian monastery, where were found gravestones with inscriptions in Greek and Coptic. Ruins of various ages extend from Merawi to the Fourth Cataract.

Leaving the Nile at this point and striking direct across the Bayuda Desert, the river is regained at a point above the Atbara confluence. Thirty miles north of the town of Shendi are the pyramids of Meroë (or Assur) in three distinct groups. From one of these pyramids was taken "the treasure of Queen Candace," now in the Berlin Museum. Many of the pyramids have a small shrine on the eastern side inscribed with debased Egyptian or Meroite hieroglyphics. These pyramids are on the right bank of the Nile, that is in the "Island of Meroë." Portions (including a harbour) of the site of the city of Meroë, at Begerawia, not far from the pyramids named, were excavated in 1909–1910 (see MEROË). In this region, and distant from the river, are the remains of several cities, notably Naga, where are ruins of four temples, one in the Classic style. On the east bank of the Blue Nile, about 13 m. above Khartum at Soba, are ruins of a Christian basilica. Farther south still, at Ceteina on the White Nile (in 1904), and at Wad el-Hadad, some miles north of Sennar, on the Blue Nile (in 1908), Christian remains have been observed.

Between the Nile at Wadi Halfa and the Red Sea are the remains of towns inhabited by the ancient miners who worked the district. The most striking of these towns is Deraheib (Castle Beautiful), so named from the picturesque situation of the castle, a large square building with pointed arches. The walls of some 500 houses still stand.

For a popular account (with many illustrations) of these ruins see J. Ward, *Our Sudan: Its Pyramids and Progress* (London, 1905). (F. R. C.)

HISTORY

A. *From the Earliest Time to the Egyptian Conquest.*—The southern regions of the Anglo-Egyptian Sudan are without recorded history until the era of the Egyptian conquest in the 19th century. In the northern regions, known as Ethiopia or Nubia, Egyptian influence made itself felt as early as the Old Empire. In process of time powerful states grew up with capitals at Napata and Meroë (see *ante* § *Archaeology* and ETHIOPIA and EGYPT). The Nubians—that is the dwellers in the Nile valley between Egypt and Abyssinia—did not embrace Christianity until the 6th century, considerably later than their Abyssinian neighbours. The Arab invasion of North Africa in the 7th century, which turned Egypt into a Mahommedan country, had not the same effect in Nubia, the Moslems, though they frequently raided the country, being unable to hold it.

Christian Kingdoms of Nubia.

On the ruins of the ancient Ethiopian states arose the Christian kingdoms of Dongola and Aloa, with capitals at Dongola and Soba (corresponding roughly to Napata and Meroë). These kingdoms continued to exist until the middle of the 14th century or later (see DONGOLA: *Mudiria*). Meanwhile Arabs of the Beni Omayya tribe, under pressure from the Beni Abbas, had begun to cross the Red Sea as early as the 8th century and to settle in the district around Sennar on the Blue Nile, a region which probably marked the southern limits of the kingdom of Aloa. The Omayya, who during the following centuries were reinforced by further immigrants from Arabia, intermarried with the negroid races, and gradually Arab influence became predominant and Islam the nominal faith of all the inhabitants of Sennar. In this way a barrier was erected between the Christians of Nubia and those of Abyssinia. By the 15th century the Arabized negro races of the Blue Nile had grown into a powerful nation known as the Funj (*q.v.*), and during that century they extended their conquests north to the borders of Egypt. The kingdom of Dongola had already been reduced to a condition of anarchy by Moslem invasions from the north. Christianity was still professed by some of the Nubians as late as the 16th century, but the whole Sudan north of the lands of the pagan negroes (roughly 12° N.) was then under Moslem sway. At that time the sultans of Darfur (*q.v.*) in the west and the sultans or kings of Sennar (the Funj rulers) in the east were the most powerful of the Mahommedan potentates.

The Funj Empire.

The first of the Funj monarchs acknowledged king of the whole of the allied tribes, of which the Hameg were next in importance to the Funj, was Amara Dunkas, who reigned *c.* 1484–1526.[1] During the reign of Adlan, *c.* 1596–1603, the fame of Sennar attracted learned men to his court from such distant places as Cairo and Bagdad. Adlan's great-grandson Badi Abu Daku attacked the Shilluk negroes and raided Kordofan. This monarch built the great mosque at Sennar, almost the only building in the town to survive the ravages of the dervishes in the 19th century. In the early part of the 18th century there was war between the Sennari and the Abyssinians, in which the last named were defeated with great slaughter. It is said that the cause of quarrel was the seizure by the king of Sennar of presents sent by the king of France to the Negus. The victory over the "infidel" Abyssinians became celebrated throughout the Mahommedan world, and Sennar was visited by many learned and celebrated men from Egypt, Arabia and India. Towards the end of the 18th century the Hameg wrested power from the Funj and the kingdom fell into decay, many of the tributary princes refusing to acknowledge the king of Sennar. These disorders continued up to the time of the conquest of the country by the Egyptians.

Conquest by Egypt.

B. *From the Egyptian Conquest to the Rise of the Mahdi.*—The conquest of Nubia was undertaken in 1820 by order of Mehemet Ali, the pasha of Egypt, and was accomplished in the two years following. In its consequences this proved one of the most important events in the history of Africa. Mehemet Ali never stated the reasons which led him to order the occupation of the country, but his leading motive was, probably, the desire to obtain possession of the mines of gold and precious stones which he believed the Sudan contained. He also saw that the revenue of Egypt was falling through the diversion, since about 1800, of the caravan routes from the Nile to the Red Sea ports, and may have wished to recapture the trade, as well as to secure a country whence thousands of slaves could be brought annually. Mehemet Ali also wished to crush the remnant of the Mamelukes who in 1812 had established themselves at Dongola, and at the same time to find employment for the numerous Albanians and Turks in his army, of whose fidelity he was doubtful.

Mehemet Ali gave the command of the army sent to Nubia to his son Ismail, who at the head of some 4000 men left Wadi Halfa in October 1820. Following the Nile route he occupied Dongola without opposition, the Mamelukes fleeing before him. (Some of them went to Darfur and Wadai, others made their way to the Red Sea. This was the final dispersal of the Mamelukes.) With the nomad Shagia, who dominated the district, Ismail had two sharp encounters, one near Korti, the other higher up the river, and in both fights Ismail was successful. Thereafter the Shagia furnished useful auxiliary cavalry to the Egyptians. Ismail remained in the Dongola province till February 1821, when he crossed the Bayuda Desert and received the submission of the meks (kings) of Berber, Shendi and Halfaya, nominal vassals of the king of Sennar. Continuing his march south Ismail reached the confluence of the White and Blue Niles and established a camp at Ras Khartum. (This camp developed into the city of Khartum.) At this time Badi, the king of Sennar, from whom all real power had been wrested by his leading councillors, determined to submit to the Egyptians, and as Ismail advanced up the Blue Nile he was met at Wad Medani by Badi who declared that he recognized Mehemet Ali as master of his kingdom. Ismail and Badi entered the town of Sennar together on the 12th of June 1821, and in this peaceable manner the Egyptians became rulers of the ancient empire of the Funj. In search of the gold-mines reported to exist farther south Ismail penetrated into the mountainous region of Fazokl, where the negroes offered a stout resistance. In February 1822 he set out on his return to Sennar and Dongola, having received reports of risings against Egyptian authority. The Egyptian soldiery had behaved throughout with the utmost barbarity, and their passage up the Nile was marked by rapine, murder, mutilation and fire. Of the rulers who had submitted to Ismail, Nair Mimr, the mek of Shendi, had been compelled to follow in the suite of the Egyptians as a sort of hostage, and this man entertained deep hatred of the pasha. On Ismail's return to Shendi, October 1822, he demanded of the mek 1000 slaves to be supplied in two days. The mek, promising compliance, invited Ismail and his chief officers to a feast in his house, around which he had piled heaps of straw. Whilst the Egyptians were feasting the mek set fire to the straw and Ismail and all his companions were burnt to death.

Ismail's death was speedily avenged. A second Egyptian army, also about 4000 strong, had followed that of Ismail's up the Nile, and striking south-west from Debba had wrested, after a sharp campaign, the province of Kordofan (1821) from the sultan of Darfur. This army was commanded by Mahommed Bey, the Defterdar, son-in-law of Mehemet Ali. Hearing of Ismail's murder the Defterdar marched to Shendi, defeated the forces of the mek, and took terrible revenge upon the inhabitants of Metemma and Shendi, most of the inhabitants, including women and children, being burnt alive. Nair Mimr escaped to the Abyssinian frontier, where he maintained his independence. Having conquered Nubia, Sennar and Kordofan the Egyptians set up a civil government, placing at the head of the administration a governor-general with practically unlimited power.[2] About this period Mehemet Ali leased from the sultan of Turkey the Red Sea ports of Suakin and Massawa, and by this means got into his hands all the trade routes of the eastern Sudan. The pasha of Egypt practically monopolized the trade of the country except that in slaves, which became a vast "industry," the lands inhabited by negro tribes on the borders of the conquered territories being raided annually for the purpose. From the negro population the army was so largely recruited that in a few years the only non-Sudanese in it were officers. The Egyptian rule proved harmful to the country. The governors-general and the leading officials were nearly all Turks, Albanians or Circassians, and, with rare exceptions, the welfare of the people formed no part of their conception of government.[3] Numerous efforts were made to extend the authority of Egypt. In 1840—previous attempts having been unsuccessful—the fertile district of Taka, watered by the Atbara and Gash and near the Abyssinian frontier, was conquered and the town of

[1] Various lists and dates of reign of the rulers of Sennar are given; reference may be made in Stokvis's *Manuel d'histoire* vol. i. (Leiden, 1888), and to *The Anglo-Egyptian Sudan*, vol. i. (London, 1905).

[2] For a list of the governors-general see *The Anglo-Egyptian Sudan*, i. p. 280 (London, 1905).

[3] Khurshid Pasha, governor-general for 13 years (1826–1839), was one of these exceptions. He gained a great reputation both for rectitude and vigour. He led expeditions up the White Nile against the Dinkas as far as Fashoda; defeated the Abyssinians on the Sennar frontier, and taught the natives of Khartum to build houses of brick.

Kassala founded. In 1837 the pasha himself visited the Sudan, going as far as Fazokl, where he inspected the goldfields.

In 1849 Abd-el-Latif Pasha became governor-general and attempted to remedy some of the evils which disfigured the administration. He remained in office, however, little more than a year, too short a period to effect reforms. The Sudan was costing Egypt more money than its revenue yielded, though it must not be forgotten that large sums found their way illicitly into the hands of the pashas. The successors of Mehemet Ali, in an endeavour to make the country more profitable, extended their conquests to the south, and in 1853 and subsequent years trading posts were established on the Upper Nile, the pioneer European merchant being John Petherick, British consular agent at Khartum.[1] Petherick sought for ivory only, but those who followed him soon found that slave-raiding was more profitable than elephant hunting. The viceroy Said, who made a rapid tour through the Sudan in 1857, found it in a deplorable condition. The viceroy ordered many reforms to be executed and proclaimed the abolition of slavery. The reforms were mainly inoperative and slavery continued. The project which Said also conceived of linking the Sudan to Egypt by railway remained unfulfilled. The Sudan at this time (*c.* 1862) is described by Sir Samuel Baker as utterly ruined by Egyptian methods of government and the retention of the country only to be accounted for by the traffic in slaves. The European merchants above Khartum had sold their posts to Arab agents, who oppressed the natives in every conceivable fashion. Ismail Pasha, who became viceroy of Egypt in 1863, gave orders for the suppression of the slave trade, and to check the operations of the Arab traders a military force was stationed at Fashoda (1865), this being the most southerly point then held by the Egyptians. Ismail's efforts to put an end to the slave trade, if sincere, were ineffective, and, moreover, south of Kordofan the authority of the government did not extend beyond the posts occupied by their troops. Ismail, however, was ambitious to extend his dominions and to develop the Sudan on the lines he had conceived for the development of Egypt. He obtained (1865) from the sultan of Turkey a firman assigning to him the administration of Suakin and Massawa; the lease which Mehemet Ali had of these ports having lapsed after the death of that pasha. Ismail subsequently (1870–1875) extended his sway over the whole coast from Suez to Cape Guardafui and garrisoned the towns of Berbera, Zaila, &c., while in 1874 the important town of Harrar, the entrepôt for southern Abyssinia, was seized by Egyptian troops. The khedive had also seized Bogos, in the hinterland of Massawa, a province claimed by Abyssinia. This action led to wars with Abyssinia, in which the Egyptians were generally beaten. Egyptian authority was withdrawn from the coast regions south of Suakin in 1884 (see below and also ABYSSINIA; ERITREA and SOMALILAND).

At the same time that Ismail annexed the seaboard he was extending his sway along the Nile valley to the equatorial lakes, and conceived the idea of annexing all the country between the Nile and the Indian Ocean. An expedition was sent (1875) to the Juba River with that object, but it was withdrawn at the request of the British government, as it infringed the rights of the sultan of Zanzibar.[2] The control of all territories south of Gondokoro had been given (April 1, 1869) to Sir Samuel Baker, who, however, only left Khartum to take up his governorship in February 1870. Reaching Gondokoro on the 26th of May following, he formally annexed that station, which he named Ismailia, to the khedival domains. Baker remained as governor of the Equatorial Provinces until August 1873, and in March 1874 Colonel C. G. Gordon took up the same post. Both Baker and Gordon made strenuous efforts towards crushing the slave trade, but their endeavours were largely thwarted by the inaction of the authorities at Khartum. Under Gordon the Upper Nile region as far as the borders of Uganda came effectively under Egyptian control, though the power of the government extended on the east little beyond the banks of the rivers. On the west the Bahr-el-Ghazal had been overrun by Arab or semi-Arab slave-dealers. Nominally subjects of the khedive, they acted as free agents, reducing the country over which they terrorized to a state of abject misery. The most powerful of the slave traders was Zobeir Pasha, who, having defeated a force sent from Khartum to reduce him to obedience, invaded Darfur (1874). The khedive, fearing the power of Zobeir, also sent an expedition to Darfur, and that country, after a stout resistance, was conquered. Zobeir claimed to be made governor-general of the new province; his request being refused, he went to Cairo to urge his claim. At Cairo he was detained by the Egyptian authorities.

The Equatorial Regions: Darfur conquered.

Though spasmodic efforts were made to promote agriculture and open up communications the Sudan continued to be a constant drain on the Egyptian exchequer. The khedive Ismail revived Said's project of a railway, and a survey for a line from Wadi Halfa to Khartum was made (1871), while a branch line to Massawa was also contemplated. As with Said's project these schemes came to naught.[3] In October 1876 Gordon left the Equatorial Provinces and gave up his appointment. In February 1877, under pressure from the British and Egyptian governments, he went to Cairo, where he was given the governorship of the whole of the Egyptian territories outside Egypt; namely, the Sudan provinces proper, the Equatorial Provinces, Darfur, and the Red Sea and Somali coasts. He replaced at Khartum Ismail Pasha Eyoub, a Turk made governor-general in 1873, who had thwarted as much as he dared all Gordon's efforts to reform. Gordon remained in the Sudan until August 1879. During his tenure of office he did much to give the Sudanese the benefit of a just and considerate government. In 1877 Gordon suppressed a revolt in Darfur and received the submission of Suliman Zobeir (a son of Zobeir Pasha), who was at the head of a gang of slave-traders on the Bahr-el-Ghazal frontier. In 1878 there was further trouble in Darfur and also in Kordofan, and Gordon visited both these provinces, breaking up many companies of slave-hunters. Meantime Suliman (acting on the instructions of his father, who was still at Cairo) had broken out into open revolt against the Egyptians in the Bahr-el-Ghazal. The crushing of Suliman was entrusted by Gordon to Romolo Gessi (1831–1881), an Italian who had previously served under Gordon on the Upper Nile. Gessi, after a most arduous campaign (1878–79), in which he displayed great military skill, defeated and captured Suliman, whom, with other ringleaders, he executed. The slave-raiders were completely broken up and over 10,000 captives released. A remnant of Zobeir's troops under a chief named Rabah succeeded in escaping westward, (see RABAH). Having conquered the province Gessi was made governor of the Bahr-el-Ghazal and given the rank of pasha.

General Gordon Governor-general.

When Gordon left the Sudan he was succeeded at Khartum by Raouf Pasha, under whom all the old abuses of the Egyptian administration were revived. At this time the high European officials in the Sudan, besides Gessi, included Emin Pasha (*q.v.*)—then a bey only—governor of the Equatorial Province since 1878, and Slatin Pasha—then also a bey—governor of Darfur. Gessi, who had most successfully governed his province, found his position under Raouf intolerable, resigned his post in September 1880 and was succeeded by Frank Lupton, an Englishman, and formerly captain of a Red Sea merchant steamer, who was given the rank of bey. At this period (1880–1882) schemes for the reorganization and better administration of the Sudan were elaborated on paper, but the revolt in Egypt under Arabi (see EGYPT: *History*) and the appearance in the Sudan of a Mahdi prevented these schemes from being put into

[1] The government monopoly in trade ceased after the death of Mehemet Ali in 1849.

[2] The Juba was quite unsuitable as a means of communication between the Indian Ocean and the Nile. The proposal made to Ismail by Gordon was to send an expedition to Mombasa and thence up the Tana River, but for some unexplained reason, or perhaps by mistake, the expedition was ordered to the Juba (see *Col. Gordon in Central Africa*, 4th ed., 1885, pp. 65, 66, 150 and 151, and *Geog. Journ.*, Feb. 1, 1909, p. 150).

[3] Up to 1877, when the work was abandoned, some 50 m. of rails had been laid from Wadi Halfa at a cost of some £450,000.

execution (assuming that the Egyptian authorities were sincere in proposing reforms).

C. *The Rise and Power of Mahdism.*—The Mahdist movement, which was utterly to overthrow Egyptian rule, derived its strength from two different causes: the oppression under which the people suffered,[1] and the measures taken to prevent the Baggara (cattle-owning Arabs) from slave trading. Venality and the extortion of the tax-gatherer flourished anew after the departure of Gordon, while the feebleness of his successors inspired in the Baggara a contempt for the authority which prohibited them pursuing their most lucrative traffic. When Mahommed Ahmed (*q.v.*), a Dongolese, proclaimed himself the long-looked-for Mahdi (guide) of Islam, he found most of his original followers among the grossly superstitious villagers of Kordofan, to whom he preached universal equality and a community of goods, while denouncing the Turks[2] as unworthy Moslems on whom God would execute judgment. The Baggara perceived in this Mahdi one who could be used to shake off Egyptian rule, and their adhesion to him first gave importance to his "mission." Mahommed Ahmed became at once the leader and the agent of the Baggara. He married the daughters of their sheikhs and found in Abdullah, a member of the Taaisha section of the tribe, his chief supporter. The first armed conflict between the Egyptian troops and the Mahdi's followers occurred in August 1881. In June 1882 the Mahdi gained his first considerable success. The capture of El Obeid on the 17th of January 1883 and the annihilation in the November following of an army of over 10,000 men commanded by Hicks Pasha (Colonel William Hicks [*q.v.*] formerly of the Bombay army) made the Mahdi undisputed master of Kordofan and Sennar. The next month, December 1883, saw the surrender of Slatin in Darfur, whilst in February 1884 Osman Digna, his amir in the Red Sea regions, inflicted a crushing defeat on some 4000 Egyptians at El Teb near Suakin. In April following Lupton Bey, governor of Bahr-el-Ghazal, whose troops and officials had embraced the Mahdist cause, surrendered and was sent captive to Omdurman, where he died on the 8th of May 1888.

The Massacre of Hicks Pasha's Army.

On learning of the disaster to Hicks Pasha's army, the British government (Great Britain having been since 1882 in military occupation of Egypt) insisted that the Egyptian government should evacuate such parts of the Sudan as they still held, and General Gordon was despatched, with Lieut.-Colonel Donald H. Stewart,[3] to Khartum to arrange the withdrawal of the Egyptian civil and military population. Gordon's instructions, based largely on his own suggestions, were not wholly consistent; they contemplated vaguely the establishment of some form of stable government on the surrender of Egyptian authority, and among the documents with which he was furnished was a firman creating him governor-general of the Sudan.[4] Gordon reached Khartum on the 18th of February 1884 and at first his mission, which had aroused great enthusiasm in England, promised success. To smooth the way for the retreat of the Egyptian garrisons and civilians he issued proclamations announcing that the suppression of the slave trade was abandoned, that the Mahdi was sultan of Kordofan, and that the Sudan was independent of Egypt. He enabled some thousands of refugees to make their escape to Assuan and collected at Khartum troops from some of the outlying stations. By this time the situation had altered for the worse and Mahdism was gaining strength among tribes in the Nile valley at first hostile to its propaganda. As the only means of preserving authority at Khartûm (and thus securing the peaceful withdrawal of the garrison) Gordon repeatedly telegraphed to Cairo asking that Zobeir Pasha might be sent to him, his intention being to hand over to Zobeir the government of the country. Zobeir (*q.v.*), a Sudanese Arab, was probably the one man who could have withstood successfully the Mahdi. Owing to Zobeir's notoriety as a slave-raider Gordon's request was refused. All hope of a peaceful retreat of the Egyptians was thus rendered impossible. The Mahdist movement now swept northward and on the 20th of May Berber was captured by the dervishes and Khartum isolated. From this time the energies of Gordon were devoted to the defence of that town. After months of delay due to the vacillation of the British government a relief expedition was sent up the Nile under the command of Lord Wolseley. It started too late to achieve its object, and on the 25th of January 1885 Khartum was captured by the Mahdi and Gordon killed. Colonel Stewart, Frank Power (British consul at Khartum) and M. Herbin (French consul), who (accompanied by nineteen Greeks) had been sent down the Nile by Gordon in the previous September to give news to the relief force, had been decoyed ashore and murdered (Sept. 18, 1884). The fall of Khartum was followed by the withdrawal of the British expedition, Dongola being evacuated in June 1885. In the same month Kassala capitulated, but just as the Mahdi had practically completed the destruction of the Egyptian power[5] he died, in this same month of June 1885. He was at once succeeded by the khalifa Abdullah, whose rule continued until the 2nd of September 1898,[6] when his army was completely overthrown by an Anglo-Egyptian force under Sir H. (afterwards Lord) Kitchener. The military operations are described elsewhere (see EGYPT: *Military Operations*), and here it is only necessary to consider the internal situation and the character of the khalifa's government. The Mahdi had been regarded by his adherents as the only true commander of the faithful, endued with divine power to conquer the whole world. He had at first styled his followers dervishes (*i.e.* religious mendicants) and given them the *jibba* as their characteristic garment or uniform. Later on he commanded the faithful to call themselves *ansar* (helpers), a reference to the part they were to play in his career of conquest, and at the time of his death he was planning an invasion of Egypt. He had liberated the Sudanese from the extortions of the Egyptians, but the people soon found that the Mahdi's rule was even more oppressive than had been that of their former masters, and after the Mahdi's death the situation of the peasantry in particular grew rapidly worse, neither life nor property being safe. Abdullah set himself steadily to crush all opposition to his own power. Mahommed Ahmed had, in accordance with the traditions which required the Mahdi to have four khalifas (lieutenants), nominated, besides Abdullah, Ali wad Helu, a sheikh of the Degheim and Kenana Arabs, and Mahommed esh Sherif, his son-in-law, as khalifas. (The other khalifaship was vacant having been declined by the sheikh es Senussi [*q.v.*]). Wad Helu and Sherif were stripped of their power and gradually all chiefs and amirs not of the Baggara tribe were got rid of except Osman Digna, whose sphere of operations was on the Red Sea coast. Abdullah's rule was a pure military despotism which brought the country to a state of almost complete agricultural and commercial ruin. He was also almost constantly in conflict either with the Shilluks, Nuers and other negro tribes of the south; with the peoples of Darfur, where at one time an anti-Mahdi gained a great following; with the Abyssinians; with the Kabbabish and other Arab tribes who

Gordon at Khartum.

The Khalifa's Rule.

[1] Writing from Darfur in April 1879 Gordon said: "The government of the Egyptians in these far-off countries is nothing else but one of brigandage of the very worst description. It is so bad that all hope of ameliorating it is hopeless."

[2] The Sudanese spoke of all foreigners as "Turks." This arose from the fact that most of the higher Egyptian officials were of Turkish nationality and that the army was officered mainly by Turks, Albanians, Circassians, &c., and included in the ranks many Bashi-Bazuks (irregulars) of non-Sudanese origin.

[3] Colonel Stewart had been sent to Khartum in 1882 on a mission of inquiry, and he drew up a valuable report, *Egypt*, No. 11 (1883).

[4] It is unnecessary here to enter upon a discussion of the precise nature of Gordon's instructions or of the measure in which he carried them out. The material for forming a judgment will be found in Gordon's *Journals* (1885), Morley's *Life of Gladstone* (1903), Fitzmaurice's *Life of Granville* (1905), and Cromer's *Modern Egypt* (1908). (See also GORDON, CHARLES GEORGE.)

[5] Sennar town held out until the 19th of August, while the Red Sea ports of Suakin and Massawa never fell into the hands of the Mahdists. The garrisons of some other towns were rescued by the Abyssinians.

[6] This period in the history of the Sudan is known as the Mahdia.

had never embraced Mahdism, or with the Italians, Egyptians and British. Notwithstanding all this opposition the khalifa found in his own tribesmen and in his black troops devoted adherents and successfully maintained his position. The attempt to conquer Egypt ended in the total defeat of the dervish army at Toski (Aug. 3, 1889). The attempts to subdue the Equatorial Provinces were but partly successful. Emin Pasha, to whose relief H. M. Stanley had gone, evacuated Wadelai in April 1889. The greater part of the region and also most of the Bahr-el-Ghazal relapsed into a state of complete savagery.

In the country under his dominion the khalifa's government was carried on after the manner of other Mahommedan states, but pilgrimages to the Mahdi's tomb at Omdurman were substituted for pilgrimages to Mecca. The arsenal and dockyard and the printing-press at Khartum were kept busy (the workmen being Egyptians who had escaped massacre). Otherwise Khartum was deserted, the khalifa making Omdurman his capital and compelling disaffected tribes to dwell in it so as to be under better control. While Omdurman grew to a huge size the population of the country generally dwindled enormously from constant warfare and the ravages of disease, small-pox being endemic. The Europeans in the country were kept prisoners at Omdurman. Besides ex-officials like Slatin and Lupton, they included several Roman Catholic priests and sisters, and numbers of Greek merchants established at Khartum. Although several were closely imprisoned, loaded with chains and repeatedly flogged, it is a noteworthy fact that none was put to death. From time to time a prisoner made his escape, and from the accounts of these ex-prisoners knowledge of the character of Dervish rule is derived in large measure. The fanaticism with which the Mahdi had inspired his followers remained almost unbroken to the end. The khalifa after the fatal day of Omdurman fled to Kordofan where he was killed in battle in November 1899. In January 1900 Osman Digna, a wandering fugitive for months, was captured. In 1902 the last surviving dervish amir of importance surrendered to the sultan of Darfur. Mahdism as a vital force in the old Egyptian Sudan ceased, however, with the Anglo-Egyptian victory at Omdurman.[1]

D. *The Anglo-Egyptian Condominium.*—Of the causes which led to the reconquest of the Sudan—the natural desire of the Egyptian government to recover lost territory, the equally natural desire in Great Britain to "avenge" the death of Gordon were among them—the most weighty was the necessity of securing for Egypt the control of the Upper Nile, Egypt being wholly dependent on the waters of the river for its prosperity. That control would have been lost had a European power other than Great Britain obtained possession of any part of the Nile valley; and at the time the Sudan was reconquered (1896–98) France was endeavouring to establish her authority on the river between Khartum and Gondokoro, as the Marchand expedition from the Congo to Fashoda demonstrated. The Nile constitutes, in the words of Lord Cromer, the true justification of the policy of re-occupation, and makes the Sudan a priceless possession for Egypt.[2]

The Sudan having been reconquered by "the joint military and financial efforts" of Great Britain and Egypt, the British government claimed "by right of conquest" to share in the settlement of the administration and legislation of the country. To meet these claims an agreement (which has been aptly called the constitutional charter of the Sudan) between Great Britain and Egypt, was signed on the 19th of January 1899, establishing the joint sovereignty of the two states throughout the Sudan.[3] The reorganization of the country had already begun, supreme power being centred in one official termed the "governor-general of the Sudan." To this post was appointed Lord Kitchener, the sirdar (commander-in-chief) of the Egyptian army, under whom the Sudan had been reconquered. On Lord Kitchener going to South Africa at the close of 1899 he was succeeded as sirdar and governor-general by Major-General Sir F. R. Wingate, who had served with the Egyptian army since 1883. Under a just and firm administration, which from the first was essentially civil, though the principal officials were officers of the British army, the Sudan recovered in a surprising manner from the woes it suffered during the Mahdia. At the head of every *mudiria* (province) was placed a British official, though many of the subordinate posts were filled by Egyptians. An exception was made in the case of Darfur, which before the battle of Omdurman had thrown off the khalifa's rule and was again under a native sovereign. This potentate, the sultan Ali Dinar, was recognized by the Sudan government, on condition of the payment of an annual tribute.

The first duty of the new administration, the restoration of public order, met with comparatively feeble opposition, though tribes such as the Nuba mountaineers, accustomed from time immemorial to raid their weaker neighbours, gave some trouble. In 1906, in 1908, and again in 1910 expeditions had to be sent against the Nubas. In the Bahr-el-Ghazal the Niam-Niams at first disputed the authority of the government, but Sultan Yambio, the recalcitrant chief, was mortally wounded in a fight in February 1905 and no further disturbance occurred. The delimitation (1903–1904) of the frontier between the Sudan and Abyssinia enabled order to be restored in a particularly lawless region, and slave-raiding on a large scale ended in that quarter with the capture and execution of a notorious offender in 1904. In Kordofan, Darfur and the Bahr-el-Ghazal the slave trade continued however for some years later.

The Regenerative Work of Great Britain.

With good administration and public security the population increased steadily. The history of the country became one of peaceful progress marked by the growing contentment of the people. The Sudan government devoted much attention to the revival of agriculture and commerce, to the creation of an educated class of natives, and to the establishment of an adequate judicial system. Their task, though one of immense difficulty, was however (in virtue of the agreement of the 19th of January 1899) free from all the international fetters that bound the administration of Egypt. It was moreover rendered easier by the decision to govern, as far as possible, in accordance with native law and custom, no attempt being made to Egyptianize or Anglicize the Sudanese. The results were eminently satisfactory. The Arab-speaking and Mahommedan population found their religion and language respected, and from the first showed a marked desire to profit by the new order. To the negroes of the southern Sudan, who were exceedingly suspicious of all strangers—whom hitherto they had known almost exclusively as slave-raiders—the very elements of civilization had, in most cases, to be taught. In these pagan regions the Sudan government encouraged the work of missionary societies, both Protestant and Roman Catholic, while discouraging propaganda work among the Moslems.

In their general policy the Sudan government adopted a system of very light taxation; low taxation being in countries such as Egypt and the Sudan the keystone of the political arch. This policy was amply justified by results. In 1899 the revenue derived from the country was £E126,000, in 1909 it had risen to £E1,040,000, despite slight reductions in taxation, a proof of the growing prosperity of the land. This prosperity was brought about largely by improving the water-supply, and thus bringing more land under cultivation, by the creation of new industries, and by the improvement of means of communication. A shorter route to the sea than that through Egypt being essential for the

[1] In the autumn of 1903 Mahommed-el-Amin, a native of Tunis, proclaimed himself the Mahdi and got together a following in Kordofan. He was captured by the governor of Kordofan and publicly executed at El Obeid. In April 1908 Abd-el-Kader, a Halowin Arab and ex-dervish, rebelled in the Blue Nile province, claiming to be the prophet Issa (Jesus). On the 29th of that month he murdered Mr C. C. Scott-Moncrieff, deputy inspector of the province, and the Egyptian mamur. The rising was promptly suppressed, Abd-el-Kader was captured and was hanged on the 17th of May.

[2] *Egypt*, No. 1 (1905), p. 119.

[3] At first Suakin was excepted from some of the provisions of this agreement, but these exceptions were done away with by a supplementary agreement of the 10th of July 1899.

commercial development of the country, a railway from the Nile near Berber to the Red Sea was built (1904–1906). This line shortened the distance from Khartum to the nearest seaport by nearly 1000 m., and by reducing the cost of carriage of merchandise enabled Sudan produce to find a profitable outlet in the markets of the world. At the same time river communications were improved and the numbers of wells on caravan roads increased. Steps were furthermore taken by means of irrigation works to regulate the Nile floods, and those of the river Gash.

To the promotion of education and sanitation, and in the administration of justice, the government devoted much energy with satisfactory results. Indeed the regenerative work of Great Britain in the Sudan has been fully as successful and even more remarkable than that of Great Britain in Egypt. A large part of this work has been accomplished by officers of the British army. Some of the most valuable suggestions about such matters as land settlement, agricultural loans, &c., emanated from officers who a short time before were performing purely military duties.

Nevertheless civil servants gradually replaced military officers in the work of administration, army officers being liable to be suddenly removed for war or other service, often at times when the presence of officials possessed of local experience was most important. In efficiency and devotion to duty the Egyptian officials under the new régime also earned high praise.

The relations of the Sudan government with its Italian, Abyssinian and French neighbours was marked by cordiality, but with the Congo Free State difficulties arose over claims made by that state to the Bahr-el-Ghazal (see AFRICA, § 5). Congo State troops were in 1904 stationed in Sudanese territory. The difficulty was adjusted in 1906 when the Congo State abandoned all claims to the Ghazal province (whence its troops were withdrawn during 1907), and it was agreed to transfer the Lado enclave (*q.v.*) to the Sudan six months after the death of the king of the Belgians. Under the terms of this agreement the Lado enclave was incorporated in the Sudan in 1910. As to the general state of the country Sir Eldon Gorst after a tour of inspection declared in his report for 1909, "I do not suppose that there is any part of the world in which the mass of the population have fewer unsatisfied wants."

Bahr-el-Ghazal and Lado.

AUTHORITIES.—Summaries of ancient and medieval history will be found in E. A. Wallis Budge, *The Egyptian Sudan* (2 vols., 1907) and *The Anglo-Egyptian Sudan* (1095), edited by Count Gleichen. The story of the Egyptian conquest and events up to 1850 are summarized in H. Deherain's *Le Soudan égyptien sous Mehemet Ali* (Paris, 1898). For the middle period of Egyptian rule see Sir Samuel Baker's *Ismailia* (1874); *Col. Gordon in Central Africa*, edited by G. Birkbeck Hill (4th ed., 1885), being extracts from Gordon's diary, 1874–1880; *Seven Years in the Soudan*, by Romolo Gessi Pasha (1892); and *Der Sudan unter ägyptischer Herrschaft*, by R. Buchta (Leipzig, 1888). The rise of Mahdism and events down to 1900 are set forth in (Sir) F. R. Wingate's *Mahdiism and the Egyptian Sudan* (1891). This book contains translations of letters and proclamations of the Mahdi and Khalifa. For this period the *Journals of Major General Gordon at Khartoum* (1885); F. Power's *Letters from Khartoum during the Siege* (1885), and the following four books written by prisoners of the dervishes are specially valuable: Slatin Pasha, *Fire and Sword in the Sudan* (1896); Father J. Ohrwalder (from the MSS. of, by F. R. Wingate), *Ten Years' Captivity in the Mahdi's Camp (1882–1892)* (1892); Father Paolo Rosignoli, *I miei dodici anni di prigionia in mezzo ai dervice del Sudan* (Mondovi, 1898); C. Neufeldt, *A Prisoner of the Khaleefa* (1899). See also G. Dujarric, *L'État mahdiste du Soudan* (Paris, 1901). For the "Gordon Relief" campaign, &c., see the British official *History of the Sudan Campaign* (1890); for the campaigns of 1896–98, H. S. L. Alford and W. D. Sword, *The Egyptian Soudan, its Loss and Recovery* (1898); G. W. Steevens, *With Kitchener to Khartum* (Edinburgh, 1898); Winston S. Churchill, *The River War* (revised ed., 1902). The story of the Fashoda incident is told mainly in British and French official despatches; consult also for this period G. Hanotaux, *Fachoda* (Paris, 1910); A. Lebon, *La Politique de la France 1896–1898* (Paris, 1901); and R. de Caix, *Fachoda, la France et l'Angleterre* (Paris, 1899). Lord Cromer's *Modern Egypt* (1908) covers Sudanese history for the years 1881–1907. Consult also the authorities cited under EGYPT): *Modern History*, and H. Pensa, *L'Egypte et le Soudan égyptien* (Paris, 1895). Unless otherwise stated the place of publication is London. (F. R. C.)

SUDATORIUM, the term in architecture for the vaulted sweating-room (*sudor*, sweat) of the Roman thermae, referred to in Vitruvius (v. 2), and there called the *concamerata sudatio*. In order to obtain the great heat required, the whole wall was lined with vertical terra-cotta flue pipes of rectangular section, placed side by side, through which the hot air and the smoke from the suspensura passed to an exit in the roof.

SUDBURY, SIMON OF (d. 1381), archbishop of Canterbury, was born at Sudbury in Suffolk, studied at the university of Paris, and became one of the chaplains of Pope Innocent VI., who sent him, in 1356, on a mission to Edward III. of England. In October 1361 the pope appointed him bishop of London, and he was soon serving the king as an ambassador and in other ways. In 1375 he succeeded William Wittlesey as archbishop of Canterbury, and during the rest of his life was a partisan of John of Gaunt. In July 1377 he crowned Richard II., and in 1378 John Wycliffe appeared before him at Lambeth, but he only took proceedings against the reformer under great pressure. In January 1380 Sudbury became chancellor of England, and the revolting peasants regarded him as one of the principal authors of their woes. Having released John Ball from his prison at Maidstone, the Kentish insurgents attacked and damaged the archbishop's property at Canterbury and Lambeth; then, rushing into the Tower of London, they seized the archbishop himself. Sudbury was dragged to Tower Hill and, on the 14th of June 1381, was beheaded. His body was afterwards buried in Canterbury Cathedral. Sudbury rebuilt part of the church of St Gregory at Sudbury, and with his brother, John of Chertsey, he founded a college in this town; he also did some building at Canterbury. His father was Nigel Theobald, and he is sometimes called Simon Theobald or Tybald.

See W. F. Hook, *Lives of the Archbishops of Canterbury.*

SUDBURY, a post town and outport of Nipissing district, Ontario, Canada, on the Canadian Pacific railway, 443 m. W. of Montreal. Pop. (1901), 2027. It has manufactures of explosives, lumber and planing mills, and is the largest nickel mining centre in the world. Gold, copper and other minerals are also raised. Practically all the ore is shipped to the United States.

SUDBURY, a market town and municipal borough of England, chiefly in the Sudbury parliamentary division of Suffolk, but partly in the Saffron Walden division of Essex. Pop. (1901), 7109. It lies on the river Stour (which is navigable up to the town), 59 m. N.E. from London by the Great Eastern railway. All Saints' parish church, consisting of chancel, nave, aisles and tower, is chiefly Perpendicular—the chancel being Decorated. It possesses a fine oaken pulpit of 1490. The church was restored in 1882. St Peter's is Perpendicular, with a finely carved nave roof. St Gregory's, once collegiate, is Perpendicular. It has a rich spire-shaped font-cover of wood, gilt and painted. The grammar school was founded by William Wood in 1491. There are some old half-timbered houses, including one very fine example. The principal modern buildings are the town-hall, Victoria hall and St Leonard's hospital. Coco-nut matting is an important manufacture; silk manufactures were transferred from London during the 19th century, and horsehair weaving was established at the same time. There are also flour-mills, malt-kilns, lime-works, and brick and tile yards. The town is governed by a mayor, 4 aldermen and 12 councillors. The borough lies wholly in the administrative county of West Suffolk. Area, 1925 acres.

The ancient Saxon borough of Sudbury (Sudbyrig, Sudberi, Suthberia) was the centre of the southern portion of the East Anglian kingdom. Before the Conquest it was a borough owned by the mother of Earl Morcar, from whom it was taken by William I., who held it in 1086. It was alienated from the Crown to an ancestor of Gilbert de Clare, 9th earl of Gloucester. In 1271 the earl gave the burgesses their first charter confirming to them all their ancient liberties and customs. The earl of March granted a charter to the mayor and bailiffs of Sudbury in 1397. In 1440 and again in 1445 the men and tenants of Sudbury obtained a royal confirmation of their privileges. They were incorporated in 1553 under the name of the mayor, aldermen and burgesses of Sudbury, and charters were granted to the town by Elizabeth, Charles II. and James II. Its constitution was reformed by the act of 1835. It was represented in parliament by two burgesses from 1558 till its disfranchisement in

1844. The lord of the borough had a market and fair in the 13th century, and three fairs in March, July and December were held in 1792. Markets still exist on Thursdays and Saturdays. Weavers were introduced by Edward III., and the town became the chief centre of the Suffolk cloth industry after the Restoration.

SUDD, or SADD (an Arabic word meaning "to dam"), the name given to the vegetable obstruction which has at various dates closed the waters of the Upper Nile to navigation. It is composed of masses of papyrus and *um suf* (*Vossia procera*) and the earth adhering to the roots of those reeds. Mingled with the papyrus and *um suf* (Arabic for "mother-of-wool") are small swimming plants and the light brittle ambach. The papyrus and *um suf* grow abundantly along the Nile banks and the connected lagoons between 7° N. and 13° N. Loosened by storms these reeds drift until they lodge on some obstruction and form a dam across the channel, converted by fresh arrivals into blocks that are sometimes 25 m. in length, and extend 15 to 20 ft. below the surface. These masses of decayed vegetation and earth, resembling peat in consistency, are so much compressed by the force of the current that men can walk over them everywhere. In parts elephants could cross them without danger. The pressure of the water at length causes the formation of a side channel or the bursting of the sudd. (For sudd cutting see NILE.)

In the Bahr-el-Ghazal the sudd, being chiefly composed of small swimming plants, is of less formidable nature than that of the main stream.

Consult, O. Deuerling, *Die Pflanzenbarren der afrikanischen Flüsse* (Munich, 1909), a valuable monograph; and the bibliography under NILE, especially Captain H. G. Lyons, *The Physiography of the Nile and its Basin* (Cairo, 1906).

SUDERMANN, HERMANN (1857–), German dramatist and novelist, was born on the 30th of September 1857 at Matziken in East Prussia, close to the Russian frontier, of a Mennonite family long settled near Elbing. His father owned a small brewery in the village of Heydekrug, and Sudermann received his early education at the Realschule in Elbing, but, his parents having been reduced in circumstances, he was apprenticed to a chemist at the age of fourteen. He was, however, enabled to enter the Realgymnasium in Tilsit, and to study philosophy and history at Königsberg University. In order to complete his studies Sudermann went to Berlin, where he was tutor in several families. He next became a journalist, was from 1881–1882 editor of the *Deutsches Reichsblatt*, and then devoted himself to novel-writing. The novels and romances *Im Zwielicht* (1886), *Frau Sorge* (1887), *Geschwister* (1888) and *Der Katzensteg* (1890) failed to bring the young author as much recognition as his first drama *Die Ehre* (1889), which inaugurated a new period in the history of the German stage. Of his other dramas the most successful were *Sodoms Ende* (1891), *Heimat* (1893), *Die Schmetterlingsschlacht* (1894), *Das Glück im Winkel* (1895), *Morituri* (1896), *Johannes* (1898), *Die drei Reiherfedern* (1899), *Johannesfeuer* (1900), *Es lebe das Leben!* (1902), *Der Sturmgeselle Sokrates* (1903) and *Stein unter Steinen* (1905). Sudermann is also the author of a powerful social novel, *Es war* (1904), which, like *Frau Sorge* and *Der Katzensteg*, has been translated into English.

See W. Kawerau, *Hermann Sudermann* (1897); H. Landsberg, *Hermann Sudermann* (1902); H. Jung, *Hermann Sudermann* (1902); H. Schoen, *Hermann Sudermann, poète dramatique et romancier* (1905); and I. Axelrod, *Hermann Sudermann* (1907).

SUE, EUGÈNE [JOSEPH MARIE] (1804–1857), French novelist, was born in Paris on the 20th of January 1804. He was the son of a distinguished surgeon in Napoleon's army, and is said to have had the empress Josephine for godmother. Sue himself acted as surgeon both in the Spanish campaign undertaken by France in 1823 and at the battle of Navarino (1828). In 1829 his father's death put him in possession of a considerable fortune, and he settled in Paris. His naval experiences supplied much of the materials of his first novels, *Kernock le pirate* (1830), *Atar-Gull* (1831), *La Salamandre* (2 vols., 1832), *La Coucaratcha* (4 vols., 1832–1834), and others, which were composed at the height of the romantic movement of 1830. In the quasi-historical style he wrote *Jean Cavalier, ou Les Fanatiques des Cevennes* (4 vols., 1840) and *Latréaumont* (2 vols., 1837). He was strongly affected by the Socialist ideas of the day, and these prompted his most famous works: *Les Mystères de Paris* (10 vols., 1842–1843) and *Le Juif errant* (10 vols., 1844–1845), which were among the most popular specimens of the *roman-feuilleton*. He followed these up with some singular and not very edifying books: *Les Sept péchés capitaux* (16 vols., 1847–1849), which contained stories to illustrate each sin, *Les Mystères du peuple* (1849–1856), which was suppressed by the censor in 1857, and several others, all on a very large scale, though the number of volumes gives an exaggerated idea of their length. Some of his books, among them the *Juif errant* and the *Mystères de Paris*, were dramatized by himself, usually in collaboration with others. His period of greatest success and popularity coincided with that of Alexandre Dumas, with whom some writers have put him on an equality. Sue has neither Dumas's wide range of subject, nor, above all, his faculty of conducting the story by means of lively dialogue; he has, however, a command of terror which Dumas seldom or never attained. From the literary point of view his style is bad, and his construction prolix. After the revolution of 1848 he sat for Paris (the Seine) in the Assembly from April 1850, and was exiled in consequence of his protest against the *coup d'état* of the 2nd of December 1851. This exile stimulated his literary production, but the works of his last days are on the whole much inferior to those of his middle period. Sue died at Annecy (Savoy) on the 3rd of August 1857.

SUEBI, or SUEVI, a collective term applied to a number of peoples in central Germany, the chief of whom appear to have been the Marcomanni, Quadi, Hermunduri, Semnones and Langobardi. From the earliest times these tribes inhabited the basin of the Elbe. The Langobardic territories seem to have lain about the lower reaches of the river, while the Semnones lay south. The Marcomanni occupied the basin of the Saale, but under their king, Maroboduus, they moved into Bohemia during the early part of Augustus's reign, while the Quadi, who are first mentioned in the time of Tiberius, lay farther east towards the sources of the Elbe. The former home of the Marcomanni was occupied by the Hermunduri a few years before the Christian era. Some kind of political union seems to have existed among all these tribes. The Semnones and Langobardi were at one time subject to the dominion of the Marcomannic king Maroboduus, and at a much later period we hear of Langobardic troops taking part against the Romans in the Marcomannic War. The Semnones claimed to be the chief of the Suebic peoples, and Tacitus describes a great religious festival held in their tribal sanctuary, at which legations were present from all the other tribes.

Tacitus uses the name Suebi in a far wider sense than that defined above. With him it includes not only the tribes of the basin of the Elbe, but also all the tribes north and east of that river, including even the Swedes (Suiones). This usage, which is not found in other ancient writers, is probably due to a confusion of the Suebi with the agglomeration of peoples under their supremacy, which as we know from Strabo extended to some at least of the eastern tribes.

In early Latin writers the term Suebi is occasionally applied to any of the above tribes. From the 2nd to the 4th century, however, it is seldom used except with reference to events in the neighbourhood of the Pannonian frontier, and here probably means the Quadi. From the middle of the 4th century onward it appears most frequently in the regions south of the Main, and soon the names Alamanni and Suabi are used synonymously. The Alamanni (*q.v.*) seem to have been, in part at least, the descendants of the ancient Hermunduri, but it is likely that they had been joined by one or more other Suebic peoples, from the Danubian region, or more probably from the middle Elbe, the land of the ancient Semnones. It is probably from the Alamannic region that those Suebi came who joined the Vandals in their invasion of Gaul, and eventually founded a kingdom in north-west Spain. After the 1st century the term Suebi seems never to be applied to the Langobardi and seldom to the Baiouarii (Bavarians), the descendants of the ancient Marcomanni. But besides the Alamannic Suebi we hear also of a people called Suebi, who shortly after the middle of the 6th century settled north of the Unstrut. There is evidence also for a people called Suebi in the district above the mouth of the Scheldt. It is likely that both these settlements were colonies from the Suebi of whom we hear in the Anglo-Saxon poem *Widsith* as neighbours of the Angli, and whose name may possibly be preserved in Schwabstedt on the Treene. The question has recently been raised whether these Suebi should be identified with the people whom the Romans called Heruli. After the 7th century the name Suebi is practically only applied to the Alamannic Suebi (Schwaben), with whom it remains a territorial designation in Württemberg and Bavaria until the present day.

Bremer in Paul's *Grundriss* (2nd ed.), iii. 915–950; H. M. Chadwick, *Origin of the English Nation*, 216 sqq. (Cambridge, 1907). (F. G. M. B.)

SUECA, a town of eastern Spain, in the province of Valencia, near the left bank of the river Júcar, and on the Silla-Cullera railway. Pop. (1900), 14,435. Sueca is separated from the Mediterranean Sea (7 m. east) by the Sierra de Cullera. It is a modern town, although many of the houses have the flat roofs, view-turrets (*miradores*) and horseshoe arches characteristic of Moorish architecture. There are a few handsome public buildings, such as the hospital, town-hall and theatre. Sueca has a thriving trade in grain and fruit from the Júcar valley, which is irrigated by waterways created by the Moors.

SUESS, EDUARD (1831–), Austrian geologist, was born in London on the 20th of August 1831, his father, a native of Saxony, having settled there as a German merchant. Three years later the family removed to Prague, and in 1845 to Vienna. Eduard Suess was educated for commercial life, but early displayed a bent for geology. At the age of nineteen he published a short sketch of the geology of Carlsbad and its mineral waters; and in 1852 he was appointed an assistant in the Imperial museum of Vienna. There he studied the fossil Brachiopoda, and manifested such ability that in 1857 he was appointed professor of geology at the university. In 1862 he relinquished his museum duties, and gave his whole time to special research and teaching, retaining his professorship until 1901. Questions of ancient physical geography, such as the former connexion between northern Africa and Europe, occupied his attention; and in 1862 he published an essay on the soils and water-supply of Vienna. He was elected a member of the town council, and in 1869 to a seat in the Diet of Lower Austria, which he retained until 1896. Meanwhile he continued his geological and palaeontological work dealing with the Tertiary strata of the Vienna Basin, also turning his attention to the problems connected with the evolution of the earth's surface-features, on which he wrote a monumental treatise. This, the great task of his life, embodied the results of personal research and of a comprehensive study of the work of the leading geologists of all countries; it is entitled *Antlitz der Erde*, of which the first volume was published in 1885, the second in 1888, and pt. i. of the third volume in 1901. The work has been translated into French, and (in part) into English. Suess was elected a corresponding member of the Institute of France in 1889, and a foreign member of the Royal Society in 1894. In 1896 the Geological Society of London awarded to him the Wollaston medal.

Memoir (with portrait), by Sir A. Geikie, *Nature* (May 4, 1905).

SUESSULA, an ancient town of Campania, Italy, in the plain 1½ m. W. of the modern Cancello, 9 m. S.E. of the ancient Capua. Its earlier history is obscure. In 338 B.C. it obtained Latin rights from Rome. In the Samnite and Hannibalic wars it was strategically important as commanding the entrance to the Caudine pass. Sulla seems to have founded a colony here. It is frequently named as an episcopal see up till the 10th century A.D., and was for a time the chief town of a small Lombard principality. It was several times plundered by the Saracens, and at last abandoned by the inhabitants in consequence of the malaria. The ruins of the town lie within the Bosco d'Acerra, a picturesque forest. They were more conspicuous in the 18th century than they now are, but traces of the theatre may still be seen, and débris of other buildings. Oscan tombs were excavated there between 1878 and 1886, and important finds of vases, bronzes, &c., have been made. The dead were generally buried within slabs of tufa arranged to form a kind of sarcophagus (see F. von Duhn in *Römische Mitteilungen*, 1887, p. 235 sqq.). Suessula lay on the line of the Via Popillia, which was here intersected by a road which ran from Neapolis through Acerrae, and on to the Via Appia, which it reached just west of the Caudine pass. On the hills above Cancello to the east of Suessula was situated the fortified camp of M. Claudius Marcellus, which covered Nola and served as a post of observation against Hannibal in Capua. (T. As.)

SUET (M. Eng. *sewet*, a diminutive of O. Fr. *seu*, *suis*, mod. *suif*, lard, from Lat. *sebum*, or *sevum*, tallow, grease, probably allied to *sapo*, soap), the hard flaked white fat lying round the kidneys of the sheep or ox; that of the pig forms lard. Beef-suet is especially used in cookery.

SUETONIUS TRANQUILLUS, GAIUS, Roman historian, lived during the end of the 1st and the first half of the 2nd century A.D. He was the contemporary of Tacitus and the younger Pliny, and his literary work seems to have been chiefly done in the reigns of Trajan and Hadrian (A.D. 98–138). His father was military tribune in the XIIIth legion, and he himself began life as a teacher of rhetoric and an advocate. To us he is known as the biographer of the twelve Caesars (including Julius) down to Domitian. The lives are valuable as covering a good deal of ground where we are without the guidance of Tacitus. As Suetonius was the emperor Hadrian's private secretary (*magister epistolarum*), he must have had access to many important documents in the Imperial archives, *e.g.* the decrees and transactions of the senate. In addition to written and official documents, he picked up in society a mass of information and anecdotes, which, though of doubtful authenticity, need not be regarded as mere inventions of his own. They give a very good idea of the kind of court gossip prevalent in Rome at the time. He was a friend and correspondent of the younger Pliny, who when appointed governor of Bithynia took Suetonius with him. Pliny also recommended him to the favourable notice of the emperor Trajan, "as a most upright, honourable, and learned man, whom persons often remember in their wills because of his merits," and he begs that he may be made legally capable of inheriting these bequests, for which under a special enactment Suetonius was, as a childless married man, disqualified. Hadrian's biographer, Aelius Spartianus, tells us that Suetonius was deprived of his private secretaryship because he had not been sufficiently observant of court etiquette towards the emperor's wife during Hadrian's absence in Britain.

The *Lives of the Caesars* has always been a popular work. It is rather a chronicle than a history. It gives no picture of the society of the time, no hints as to the general character and tendencies of the period. It is the emperor who is always before us, and yet the portrait is drawn without any real historical judgment or insight. It is the personal anecdotes, several of which are very amusing, that give the lives their chief interest; but the author panders rather too much to a taste for scandal and gossip. None the less he throws considerable light on an important period, and next to Tacitus and Dio Cassius is the chief (sometimes the only) authority. The language is clear and simple. The work was continued by Marius Maximus (3rd century), who wrote a history of the emperors from Nerva to Elagabalus (now lost). Suetonius was a voluminous writer. Of his *De viris illustribus*, the lives of Terence and Horace, fragments of those of Lucan and the elder Pliny and the greater part of the chapter on grammarians and rhetoricians, are extant. Other works by him (now lost) were: *Prata* (= λειμῶνες = patch-work), in ten books, a kind of encyclopaedia; the *Roman Year*, *Roman Institutions and Customs*, *Children's Games among the Greeks*, *Roman Public Spectacles*, *On the Kings*, *On Cicero's Republic*.

Editio princeps, 1470; editions by great scholars: Erasmus, Isaac Casaubon, J. G. Graevius, P. Burmann; the best complete annotated edition is still that of C. G. Baumgarten-Crusius (1816); recent editions by H. T. Peck (New York, 1889); Leo Preud'homme (1906); M. Ihm (1907). Editions of separate lives: *Augustus*, by E. S. Shuckburgh (with useful introduction, 1896); *Claudius*, by H. Smilda (1896), with notes and parallel passages from other authorities. The best editions of the text are by C. L. Roth (1886), and A. Reifferscheid (not including the *Lives*, 1860). On the *De viris illustribus*, see

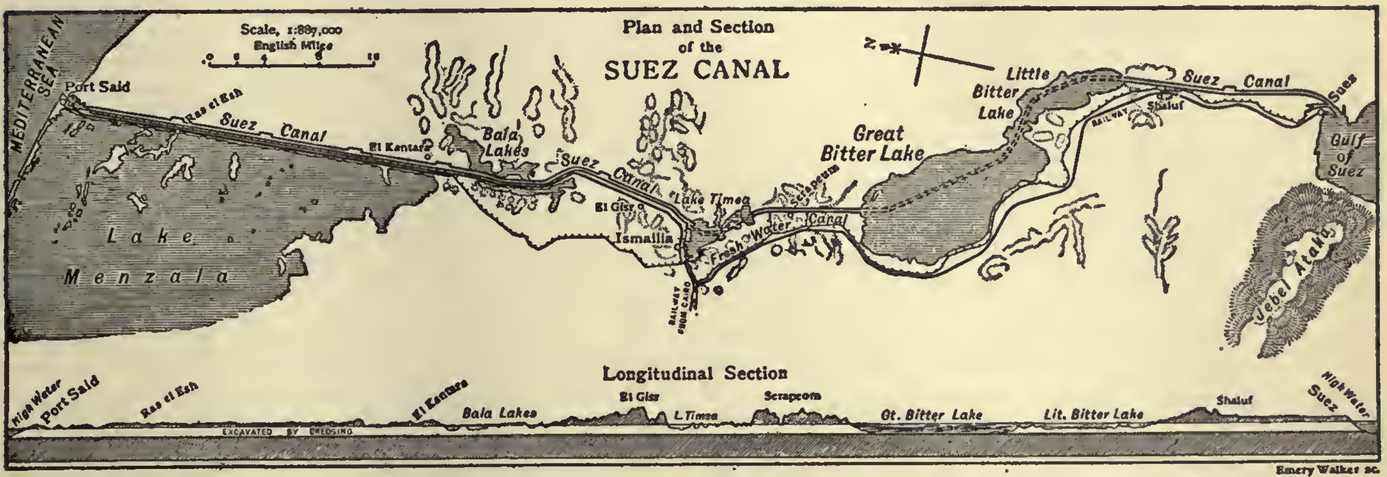
G. Körtge in *Dissert. philolog. halenses* (1900), vol. xiv.; and, above all, A. Macé, *Essai sur Suétone* (1900), with an exhaustive bibliography. There are English translations by Philemon Holland (reprinted in the *Tudor Translations*, 1900), and by Thomson and Forester (in Bohn's *Classical Library*).

SUEZ, a port of Egypt on the Red Sea and southern terminus of the Suez Canal (*q.v.*), situated at the head of the Gulf of Suez in 29° 58′ 37″ N., 32° 31′ 18″ E. It is 80 m. E. by S. of Cairo in a direct line but 148 m. by rail, and is built on the north-west point of the gulf. Pop. (1907), 18,347. From the heights to the north, where there is a khedival chalet, there is a superb view to the south with the Jebel Ataka on the right, Mt Sinai on the left and the waters of the gulf between. Suez is supplied with water by the fresh-water canal, which starts from the Nile at Cairo and is terminated at Suez by a lock which, north of the town, joins it to the gulf. Before the opening of this canal in 1863 water had to be brought from "the Wells of Moses," a small oasis 3 m. distant on the east side of the gulf. About 2 m. south of the town are the harbours and quays constructed on the western side of the Suez Canal at the point where the canal enters the gulf. The harbours are connected with the town by an embankment and railway built across a shallow, dry at low water save for a narrow channel. On one of the quays is a statue to Thomas Waghorn, the organizer of the "overland route" to India. The ground on which the port is built has all been reclaimed from the sea. The accommodation provided includes a dry dock 410 ft. long, 100 ft. broad and nearly 36 ft. deep. There are separate basins for warships and merchant ships, and in the roadstead at the mouth of the canal is ample room for shipping. Suez is a quarantine station for pilgrims from Mecca; otherwise its importance is due almost entirely to the ships using the canal.

In the 7th century a town called Kolzum stood, on a site adjacent to that of Suez, at the southern end of the canal which then joined the Red Sea to the Nile. Kolzum retained some of the trade of Egypt with Arabia and countries farther east long after the canal was closed, but by the 13th century it was in ruins and Suez itself, which had supplanted it, was also, according to an Arab historian, in decay. On the Ottoman conquest of Egypt in the 16th century Suez became a naval as well as a trading station, and here fleets were equipped which for a time disputed the mastery of the Indian Ocean with the Portuguese. According to Niebuhr, in the 18th century a fleet of nearly twenty vessels sailed yearly from Suez to Jidda, the port of Mecca and the place of correspondence with India. When the French occupied Suez in 1798 it was a place of little importance, and the conflicts which followed its occupation in 1800 by an English fleet laid the greater part in ruins. The overland mail route from England to India by way of Suez was opened in 1837. The regular Peninsular & Oriental steamer service began a few years later, and in 1857 a railway was opened from Cairo through the desert. This line is now abandoned in favour of the railway which follows the canal from Suez to Ismailia, and then ascends the Wadi Tumilat to Zagazig, whence branches diverge to Cairo and Alexandria.

SUEZ CANAL. Before the construction of the Suez Canal there was no direct water communication between the Mediterranean and the Red Sea, but at various eras such communication existed by way of the Nile. Trade between Egypt and countries to the east was originally overland to ports south of the Gulf of Suez; the proximity of the roadstead at the head of that gulf to Memphis and the Delta nevertheless marked it as the natural outlet for the Red Sea commerce of Lower Egypt. The fertile Wadi Tumilat extending east of the Nile valley almost to the head of the gulf (which in ancient times reached north to the Bitter Lakes) afforded an easy road between the Nile and the Red Sea, while the digging of a navigable canal connecting the river and the gulf gave the northern route advantages not possessed by the desert routes farther south, *e.g.* that between Coptos and Kosseir. Aristotle, Strabo and Pliny attribute to the legendary Sesostris (*q.v.*) the distinction of being the first of the pharaohs to build a canal joining the Nile and the Red Sea. From an inscription on the temple at Karnak it would appear that such a canal existed in the time of Seti I. (1380 B.C.). This canal diverged from the Nile near Bubastis and was carried along the Wadi Tumilat to Heroopolis, near Pithom, a port at the head of the Heroopolite Gulf (the Bitter Lakes of to-day). The channel of this canal is still traceable in parts of the Wadi Tumilat, and its direction was frequently followed by the engineers of the fresh-water canal. Seti's canal appears to have fallen into decay or to have been too small for later requirements, for Pharaoh Necho (609 B.C.) began to build another canal; possibly his chief object was to deepen the channel between the Heroopolite Gulf and the Red Sea, then probably silting up. Necho's canal was not completed—according to Herodotus 120,000 men perished in the undertaking. Darius (520 B.C.) continued the work of Necho, rendering navigable the channel of the Heroopolite Gulf, which had become blocked. Up to this time there appears to have been no connexion between the waters of the Red Sea and those of the Bubastis-Heroopolis canal; vessels coming from the Mediterranean ascended the Pelusiac arm of the Nile to Bubastis and then sailed along the canal to Heroopolis, where their merchandise had to be transferred to the Red Sea ships. Ptolemy Philadelphus (285 B.C.) connected the canal with the waters of the sea, and at the spot where the junction was effected he built the town of Arsinoe. The dwindling of the Pelusiac branch of the Nile rendered this means of communication impossible by the time of Cleopatra (31 B.C.). Trajan (A.D. 98) is said to have repaired the canal, and, as the Pelusiac branch was no longer available for navigation, to have built a new canal between Bubastis and Babylon (Old Cairo), this new canal being known traditionally as Amnis Trajanus or Amnis Augustus. According to H. R. Hall, however, "It is very doubtful if any work of this kind, beyond repairs, was undertaken in the times of the Romans; and it is more probable that the new canal was the work of ʽAmr" (the Arab conqueror of Egypt in the 7th century). The canal was certainly in use in the early years of the Moslem rule in Egypt; it is said to have been closed *c.* A.D. 770 by order of Abū Jaʽfar (Mansur), the second Abbasid caliph and founder of Bagdad, who wished to prevent supplies from reaching his enemies in Arabia by this means. ʽAmr's canal (of which the Khalig which passed through Cairo and was closed in 1897 is said to have formed part) had its terminus on the Red Sea south of the Heroopolite Gulf near the present town of Suez. In this neighbourhood was the ancient city of Clysma, to which in ʽAmr's time succeeded Kolzum, perhaps an Arabic corruption of Clysma. The exact situation of Clysma is unknown, but Kolzum occupied the site of Suez, the hills north of which are still called Kolzum. After the closing of the canal in the 8th century it does not appear for certain that it was ever restored, although it is asserted that in the year 1000 Sultan Hakim rendered it navigable. If so it must speedily have become choked up again. Parts of the canal continued to be filled during the Nile inundations until Mehemet Ali (A.D. 1811) ordered it to be closed; the closing, however, was not completely effected, for in 1861 the old canal from Bubastis still flowed as far as Kassassin. This part of the canal, after over 2500 years of service, was utilized by the French engineers in building the fresh-water canal from Cairo to Suez in 1861–1863. This canal follows the lines of that of ʽAmr (or Trajan).

Maritime Canal Projects.—Apart from water communication between the Mediterranean and the Red Sea by way of the Nile, the project of direct communication by a canal piercing the isthmus of Suez was entertained as early as the 8th century A.D. by Hārūn al-Rashīd, who is said to have abandoned the scheme, being persuaded that it would be dangerous to lay open the coast of Arabia to the Byzantine navy. After the discovery of the Cape route to India at the close of the 15th century, the Venetians, who had for centuries held the greater part of the trade of the East with Europe via Egypt and the Red Sea, began negotiations with the Egyptians for a canal across the isthmus, but the conquest of Egypt by the Turks put an end to these designs. In 1671 Leibnitz in his proposals to Louis XIV. of France regarding an expedition to Egypt recommended the making of a maritime canal, and the Sheikh al-Balad Ali Bey (*c.* 1770) wished to carry out the project. Bonaparte when in Egypt in 1798 ordered the isthmus to be surveyed as a preliminary to the digging of a canal across it, and the engineer he employed, J. M. Lepère, came to the conclusion that there was a difference in level of 29 ft. between the Red Sea and the Mediterranean. This view was combated at the time by Laplace and Fourier on general grounds, and was finally disproved in 1846–1847 as the result of surveys made at the instance of the Société d'Études pour le Canal de Suez. This society was organized in 1846 by Prosper Enfantin, the Saint Simonist, who thirteen years before had visited Egypt in connexion with a scheme for making a canal across the isthmus of Suez, which, like the canal across the isthmus of Panama, was part of the Saint Simonist programme for the regeneration of the world. The expert commission appointed by this society reported by a majority in favour of Paulin Talabot's plan, according to which the canal would have run from Suez to Alexandria by way of Cairo.



(Topography only from *L'Isthme et le Canal de Suez*, by G. Charles-Roux, by permission of Messrs Hachette & Co.)

For some years after this report no progress was made; indeed, the society was in a state of suspended animation when in 1854 Ferdinand de Lesseps came to the front as the chief exponent of the idea. He had been associated with the Saint Simonists and for many years had been keenly interested in the question. His opportunity came in 1854 when, on the death of Abbas Pasha, his friend Said Pasha became viceroy of Egypt. From Said on the 30th of November 1854 he obtained a concession authorizing him to constitute the Compagnie Universelle du Canal Maritime de Suez, which should construct a ship canal through the isthmus, and soon afterwards in concert with two French engineers, Linant Bey and Mougel Bey, he decided that the canal should run in a direct line from Suez to the Gulf of Pelusium, passing through the depressions that are now Lake Timsa and the Bitter Lakes, and skirting the eastern edge of Lake Menzala. In the following year an international commission appointed by the viceroy approved this plan with slight modifications, the chief being that the channel was taken through Lake Menzala instead of along its edge, and the northern termination of the canal moved some 17½ m. westward where deep water was found closer to the shore. This plan, according to which there were to be no locks, was the one ultimately carried out, and it was embodied in a second and amplified concession, dated the 5th of January 1856, which laid on the company the obligation of constructing, in addition to the maritime canal, a fresh-water canal from the Nile near Cairo to Lake Timsa, with branches running parallel to the maritime canal, one to Suez and the other to Pelusium. The concession was to last for 99 years from the date of the opening of the canal between the Red Sea and the Mediterranean, after which, in default of other arrangements, the canal passes into the hands of the Egyptian government. The confirmation of the sultan of Turkey being required, de Lesseps went to Constantinople to secure it, but found himself baffled by British diplomacy; and later in London he was informed by Lord Palmerston that in the opinion of the British government the canal was a physical impossibility, that if it were made it would injure British maritime supremacy, and that the proposal was merely a device for French interference in the East.

Although the sultan's confirmation of the concession was not actually granted till 1866, de Lesseps in 1858 opened the subscription lists for his company, the capital of which was 200 million francs in 400,000 shares of 500 francs each. In less than a month 314,494 shares were applied for; of these over 200,000 were subscribed in France and over 96,000 were taken by the Ottoman Empire. From other countries the subscriptions were trifling, and England, Austria and Russia, as well as the United States of America, held entirely aloof. The residue of 85,506 shares[1] was taken over by the viceroy. On the 25th of April 1859 the work of construction was formally begun, the first spadeful of sand being turned near the site of Port Said, but progress was not very rapid. By the beginning of 1862 the fresh-water canal had reached Lake Timsa, and towards the end of the same year a narrow channel had been formed between that lake and the Mediterranean. In 1863 the fresh-water canal was continued to Suez.

So far the work had been performed by native labour; the concession of 1856 contained a provision that at least four-fifths of the labourers should be Egyptians, and later in the same year Said Pasha undertook to supply labourers as required by the engineers of the canal company, which was to house and feed them and pay them at stipulated rates. Although the wages and the terms of service were better than the men obtained normally, this system of forced labour was strongly disapproved of in England, and the khedive Ismail who succeeded Said on the latter's death in 1863 also considered it as being contrary to the interests of his country. Hence in July the Egyptian foreign minister, Nubar Pasha, was sent to Constantinople with the proposal that the number of labourers furnished to the company should be reduced, and that it should be made to hand back to the Egyptian government the lands that had been granted it by Said in 1856. These propositions were approved by the sultan, and the company was informed that if they were not accepted the works would be stopped by force. Naturally the company objected, and in the end the various matters in dispute were referred to the arbitration of the emperor Napoleon III. By his award, made in July 1864, the company was allowed 38 million francs as an indemnity for the abolition of the *corvée*, 16 million francs in respect of its retrocessions of that portion of the fresh-water canal that lay between Wadi, Lake Timsa and Suez (the remainder had already been handed back by agreement), and 30 million francs in respect of the lands which had been granted it by Said. The company was allowed to retain a certain amount of land along the canals, which was necessary for purposes of construction, erection of workshops, &c., and it was put under the obligation of finishing the fresh-water canal between Wadi and

[1] These formed part of the 176,602 shares which were bought for the sum of £3,976,582 from the khedive by England in 1875 at the instance of Lord Beaconsfield (*q.v.*).

Suez to such dimensions that the depth of water in it would be $2\frac{1}{2}$ metres at high Nile and at least 1 metre at low Nile. The supply of Port Said with water it was allowed to manage by any means it chose; in the first instance it laid a double line of iron piping from Timsa, and it was not till 1885 that the original plan of supplying the town by a branch of the fresh-water canal was carried out. The indemnity, amounting to a total of 84 million francs, was to be paid in instalments spread over 15 years.

The abolition of forced labour was probably the salvation of the enterprise, for it meant the introduction of mechanical appliances and of modern engineering methods. The work was divided into four contracts. The first was for the supply of 250,000 cubic metres of concrete blocks for the jetties of Port Said; the second, for the first 60 kilometres of the channel from Port Said, involved the removal of 22 million cubic metres of sand or mud; the third was for the next length of 13 kilometres, which included the cutting through the high ground at El Gisr; and the fourth and largest was for the portion between Lake Timsa and the Red Sea. The contractors for this last section were Paul Borel and Alexandre Levalley, who ultimately became responsible also for the second or 60 kilometres contract. For the most part the material was soft and therefore readily removed. At some points, however, as at Shaluf and Serapeum, rock was encountered. Much of the channel was formed by means of dredgers. Through Lake Menzala, for instance, native workmen made a shallow channel by scooping out the soil with their hands and throwing it out on each side to form the banks; dredgers were then floated in and completed the excavation to the required depth, the soil being delivered on the other side of the banks through long spouts. At Serapeum, a preliminary shallow channel having been dug out, water was admitted from the fresh-water canal, the level of which is higher than that of the ship canal, and the work was completed by dredgers from a level of about 20 ft. above the sea. At El Gisr, where the soil, composed largely of loose sand, rises 60 ft. above the sea, the contractor, Alphonse Couvreux, employed an excavator of his own design, which was practically a bucket-dredger working in the dry. A long arm projecting downwards at an angle from an engine on the bank carried a number of buckets, mounted on a continuous chain, which scooped up the stuff at the bottom and discharged it into wagons at the top.

In 1865 de Lesseps, to show the progress that had been made, entertained over 100 delegates from chambers of commerce in different parts of the world, and conducted them over the works. In the following year the company, being in need of money, realized 10 million francs by selling to the Egyptian government the estate of El Wadi, which it had purchased from Said, and it also succeeded in arranging that the money due to it under the award of 1864 should be paid off by 1869 instead of 1879. Its financial resources still being insufficient, it obtained in 1867 permission to invite a loan of 100 million francs; but though the issue was offered at a heavy discount it was only fully taken up after the attractions of a lottery scheme had been added to it. Two years later the company got 30 million francs from the Egyptian government in consideration of abandoning certain special rights and privileges that still belonged to it and of handing over various hospitals, workshops, buildings, &c., which it had established on the isthmus. The government liquidated this debt, not by a money payment, but by agreeing to forego for 25 years the interest on the 176,602 shares it held in the company, which was thus enabled to raise a loan to the amount of the debt. Altogether, up to the end of the year (1869) in which the canal was sufficiently advanced to be opened for traffic, the accounts of the company showed a total expenditure of 432,807,882 francs, though the International Technical Commission in 1856 had estimated the cost at only 200 millions for a canal of larger dimensions.

The formal opening of the canal was celebrated in November 1869. On the 16th there was an inaugural ceremony at Port Said, and next day 68 vessels of various nationalities, headed by the "Aigle" with the empress Eugénie on board, began the passage, reaching Ismailia (Lake Timsa) the same day. On the 19th they continued their journey to the Bitter Lakes, and on the 20th they arrived at Suez. Immediately afterwards regular traffic began. In 1870 the canal was used by nearly 500 vessels, but the receipts for the first two years of working were considerably less than the expenses. The company attempted to issue a loan of 20 million francs in 1871, but the response was small, and it was only saved from bankruptcy by a rapid increase in its revenues.

The total length of the navigation from Port Said to Suez is 100 m. The canal was originally constructed to have a depth of 8 metres with a bottom width of 22 metres, but it soon became evident that its dimensions must be enlarged. Certain improvements in the channel were started in 1876, but a more extensive plan was adopted in 1885 as the result of the inquiries of an international commission which recommended that the depth should be increased first to $8\frac{1}{2}$ metres and finally to 9 metres, and that the width should be made on the straight parts a minimum of 65 metres between Port Said and the Bitter Lakes, and of 75 metres between the Bitter Lakes and Suez, increasing on curves to 80 metres. To pay for these works a loan of 100 million francs was issued. These widenings greatly improved the facilities for ships travelling in opposite directions to pass each other. In the early days of the canal, except in the Bitter Lakes, vessels could pass each other only at a few crossing places or gares, which had a collective length of less than a mile; but owing to the widenings that have been carried out, passing is now possible at any point over the greater part of the canal, one vessel stopping while the other proceeds on her way. From March 1887 navigation by night was permitted to ships which were provided with electric search-lights, and now the great majority avail themselves of this facility. By these measures the average time of transit, which was about 36 hours in 1886, has been reduced by half. The maximum speed permitted in the canal itself is 10 kilomètres an hour.

The dues which the canal company was authorized to charge by its concession of 1856 were 10 francs a ton. In the first instance they were levied on the tonnage as shown by the papers on board each vessel, but from March 1872 they were charged on the gross register tonnage, computed according to the method of the British Merchant Shipping Act 1854. The result was that the shipowners had to pay more, and, objections being raised, the whole question of the method of charge was submitted to an international conference which met at Constantinople in 1873. It fixed the dues at 10 francs per net register ton (English reckoning) with a surtax of 4 francs per ton, which, however, was to be reduced to 3 francs in the case of ships having on board papers showing their net tonnage calculated in the required manner. It also decided that the surtax should be gradually diminished as the traffic increased, until in the year after the net tonnage passing through the canal reached 2,600,000 tons it should be abolished. De Lesseps protested against this arrangement, but on the sultan threatening to enforce it, if necessary by armed intervention, he gave in and brought the new tariff into operation in April 1874. By an arrangement with the canal company, signed in 1876, the British government, which in 1875 by the purchase of the khedive's shares, had become a large shareholder, undertook negotiations to secure that the successive reductions of the tariff should take effect on fixed dates, the sixth and last instalment of 50 centimes being removed in January 1884, after which the maximum rate was to be 10 francs per official net ton. But before this happened British shipowners had started a vigorous agitation against the rates, which they alleged to be excessive, and had even threatened to construct a second canal. In consequence a meeting was arranged between them and representatives of the canal company in London in November 1883, and it was agreed that in January 1885 the dues should be reduced to $9\frac{1}{2}$ francs a ton, that subsequently they should be lowered on a sliding scale as the dividend increased, and that after the dividend reached 25% all the surplus profits should be applied in reducing the rates until they were lowered to 5 francs a ton. Under this arrangement they were fixed at $7\frac{3}{4}$ francs per ton at the beginning of 1906. For ships in ballast reduced rates are in force. For passengers the dues remain at 10 francs a head, the figure at which they were originally fixed.

By the concessions of 1854 and 1856 the dues were to be the same for all nations, preferential treatment of any kind being forbidden, and the canal and its ports were to be open "comme passages neutres" to every merchant ship without distinction of nationality. The question of its formal neutralization by international agreement was raised in an acute form during the Egyptian crisis of 1881-82, and in August of the latter year a few weeks before the battle of Tel-el-Kebir, navigation upon it was suspended for four days at the instance of Sir Garnet Wolseley, who was in command of the British forces. At the international conference which was then sitting at Constantinople various proposals were put forward to ensure the use of the canal to all nations, and ultimately at Constantinople on the 29th of October 1888 Great Britain, Germany, Austria, Spain, France, Italy, the Netherlands, Russia and Turkey signed the Suez Canal Convention, the purpose of which was to ensure that the canal should "always be free and open, in time of war as in time of peace, to every vessel of commerce or of war, without distinction of flag." Great Britain, however, in signing, formulated a reservation that the provisions of the convention should only apply so far as they were compatible with the actual situation, namely the "present transitory and exceptional condition of Egypt," and so far as they would not fetter the liberty of action of the British government during its occupation of that country. But by the Anglo-French agreement of the 8th of April 1904 Great Britain declared her adherence to the stipulations of the convention, and agreed to their being put in force, except as regards a provision by which the agents in Egypt of the signatory Powers of the convention were to meet once a year to take note of the due execution of the treaty. It was by virtue of this new agreement that the Russian warships proceeding to the East in 1904–1905 were enabled to use the canal, although passage was prohibited to Spanish warships in 1898 during the war between Spain and the United States.

L'Isthme et le Canal de Suez, historique, état actuel, by J. Charles-Roux (2 vols., Paris 1901), contains reprints of various official documents relating to the canal, with plates, maps and a bibliography extending to 1499 entries.

SUFFOLK, EARLS AND DUKES OF. These English titles were borne in turn by the families of Ufford, Pole, Brandon, Grey and Howard. A certain holder of land in Suffolk, named John de Peyton, had a younger son Robert, who acquired the lordship of Ufford in that county and was known as Robert de Ufford. He held an important place in the government of Ireland under Edward I. and died in 1298; his son Robert (1279–1316) was created Baron Ufford by a writ of summons to parliament in 1309, and increased his possessions by marriage with Cicely, daughter and heiress of Robert de Valoines. This Robert had several sons, one of whom was Sir Ralph de Ufford (d. 1346), justiciar of Ireland, who married Maud, widow of William de Burgh, earl of Ulster, and daughter of Henry Plantagenet, earl of Lancaster. Robert's eldest surviving son, another Robert (*c.* 1298–1369), was an associate of the young king Edward III., and was one of the nobles who arrested Roger Mortimer in 1330. In 1337 he was created earl of Suffolk. The earl was employed by Edward III. on high military and diplomatic duties and was present at the battles of Creçy and Poitiers. His son William, the 2nd earl (*c.* 1339–1382), held important appointments under Edward III. and Richard II. He played a leading part in the suppression of the Peasants' Revolt in 1381, but in the same year he supported the popular party in parliament in the attack on the misgovernment of Richard II. Although twice married he left no sons, and his earldom became extinct, his extensive estates reverting to the Crown.

In 1385 the earldom of Suffolk and the lands of the Uffords were granted by Richard II. to his friend Michael Pole (*c.* 1330–1389), a son of Sir William atte Pole, a baron of the exchequer and a merchant (see POLE FAMILY). After an active public life as the trusted adviser of Richard II. Pole was dismissed from his office of chancellor, was impeached and sentenced to death, but escaped to France, where he died. His titles and estates were forfeited, but in 1399 the earldom of Suffolk and most of the estates were restored to his son Michael (*c.* 1361–1415). Michael, the 3rd earl (1394–1415), was killed at the battle of Agincourt, and the earldom passed to his brother William (1396–1450), who was created earl of Pembroke in 1443, marquess of Suffolk in 1444, and duke of Suffolk in 1448 (see SUFFOLK, WILLIAM DE LA POLE, DUKE OF). The duke's son, John, 2nd duke of Suffolk (1442–1491), married Elizabeth, daughter of Richard, duke of York, and sister of King Edward IV., by whom he had six sons. The eldest, John (*c.* 1464–1487), was created earl of Lincoln, and was named heir to the throne by Richard III. He was killed fighting against Henry VII. at the battle of Stoke, and was attainted. His brother Edmund (*c.* 1472–1513) should have succeeded his father in the dukedom in 1491, but he surrendered this to Henry VII. in return for some of the estates forfeited by the earl of Lincoln, and was known simply as earl of Suffolk. Having incurred the displeasure of the king, he left his own country in 1501 and sought help for an invasion of England. Consequently he was attainted in 1504 and was handed over in 1506 to Henry. He was kept in prison until 1513, when he was beheaded by Henry VIII. His brother Richard now called himself duke of Suffolk, and put forward a claim to the English crown. Known as the "white rose," he lived abroad until 1525, when he was killed at the battle of Pavia.

In 1514 the title of duke of Suffolk was granted by Henry VIII. to his friend, Charles Brandon (see SUFFOLK, CHARLES BRANDON, DUKE OF) and it was borne successively by his two sons, Henry and Charles, becoming extinct when Charles died in July 1551. In the same year it was revived in favour of Henry Grey, marquess of Dorset, who had married Frances, a daughter of the first Brandon duke. Grey, who became marquess of Dorset in 1530, was a prominent member of the reforming party during the reign of Edward VI. He took part in the attempt to make his daughter, Jane, queen of England in 1553, but as he quickly made his peace with Mary he was not seriously punished. In 1554, however, he took part in the rising headed by Sir Thomas Wyat; he was captured, tried for treason and beheaded in February 1554, when the dukedom again became extinct. In 1603 Thomas Howard, Lord Howard de Walden, son of Thomas Howard, 4th duke of Norfolk, was created earl of Suffolk, and the earldom has been held by his descendants to the present day (see SUFFOLK, THOMAS HOWARD, 1st earl of).

SUFFOLK, CHARLES BRANDON, 1ST DUKE OF (*c.* 1484–1545), was the son of William Brandon, standard-bearer of Henry VII., who was slain by Richard III. in person on Bosworth Field. Charles Brandon was brought up at the court of Henry VII. He is described by Dugdale as "a person comely of stature, high of courage and conformity of disposition to King Henry VIII.," with whom he became a great favourite. He held a succession of offices in the royal household, becoming master of the horse in 1513, and received many valuable grants of land. On the 15th of May 1513 he was created Viscount Lisle, having entered into a marriage contract with his ward, Elizabeth Grey, Viscountess Lisle in her own right, who, however, refused to marry him when she came of age. He distinguished himself at the sieges of Terouenne and Tournai in the French campaign of 1513. One of the agents of Margaret of Savoy, governor of the Netherlands, writing from before Terouenne, reminds her that Lord Lisle is a second king and advises her to write him a kind letter. At this time Henry VIII. was secretly urging Margaret to marry Brandon, whom he created duke of Suffolk, though he was careful to disclaim (March 4, 1514) any complicity in the project to her father, the emperor Maximilian I. The regent herself left a curious account of the proceedings (*Letters and Papers of Henry VIII.* vol. i. 4850-4851). Brandon took part in the jousts which celebrated the marriage of Mary Tudor, Henry's sister, with Louis XII.

of France. He was accredited to negotiate various matters with Louis, and on his death was sent to congratulate the new king Francis I. An affection between Suffolk and the dowager queen Mary had subsisted before her marriage, and Francis roundly charged him with an intention to marry her. Francis, perhaps in the hope of Queen Claude's death, had himself been one of her suitors in the first week of her widowhood, and Mary asserted that she had given him her confidence to avoid his importunities. Francis and Henry both professed a friendly attitude towards the marriage of the lovers, but Suffolk had many political enemies, and Mary feared that she might again be sacrificed to political considerations. The truth was that Henry was anxious to obtain from Francis the gold plate and jewels which had been given or promised to the queen by Louis in addition to the reimbursement of the expenses of her marriage with the king; and he practically made his acquiescence in Suffolk's suit dependent on his obtaining them. The pair cut short the difficulties by a private marriage, which Suffolk announced to Wolsey, who had been their fast friend, on the 5th of March. Suffolk was only saved from Henry's anger by Wolsey, and the pair eventually agreed to pay to Henry £24,000 in yearly instalments of £1000, and the whole of Mary's dowry from Louis of £200,000, together with her plate and jewels. They were openly married at Greenwich on the 13th of May. The duke had been twice married already, to Margaret Mortimer and to Anne Browne, to whom he had been betrothed before his marriage with Margaret Mortimer. Anne Browne died in 1511, but Margaret Mortimer, from whom he had obtained a divorce on the ground of consanguinity, was still living. He secured in 1528 a bull from Pope Clement II. assuring the legitimacy of his marriage with Mary Tudor, and of the daughters of Anne Browne, one of whom, Anne, was sent to the court of Margaret of Savoy. After his marriage with Mary, Suffolk lived for some years in retirement, but he was present at the Field of the Cloth of Gold in 1520, and in 1523 he was sent to Calais to command the English troops there. He invaded France in company with Count de Buren, who was at the head of the Flemish troops, and laid waste the north of France, but disbanded his troops at the approach of winter. Suffolk was entirely in favour of Henry's divorce from Catherine of Aragon, and in spite of his obligations to Wolsey he did not scruple to attack him when his fall was imminent. The cardinal, who was acquainted with Suffolk's private history, reminded him of his ingratitude: "If I, simple cardinal, had not been, you should have had at this present no head upon your shoulders wherein you should have had a tongue to make any such report in despite of us." After Wolsey's disgrace Suffolk's influence increased daily. He was sent with the duke of Norfolk to demand the great seal from Wolsey; the same noblemen conveyed the news of Anne Boleyn's marriage to Queen Catherine, and Suffolk acted as high steward at the new queen's coronation. He was one of the commissioners appointed by Henry to dismiss Catherine's household, a task which he found distasteful. He supported Henry's ecclesiastical policy, receiving a large share of the plunder after the suppression of the monasteries. In 1544 he was for the second time in command of an English army for the invasion of France. He died at Guildford on the 24th of August in the following year.

After the death of Mary Tudor on the 24th of June 1533 he had married in 1534 his ward Catherine (1520-1580), Baroness Willoughby de Eresby in her own right, then a girl of fifteen. His daughters by his marriage with Anne Browne were Anne, who married firstly Edward Grey, Lord Powys, and, after the dissolution of this union, Randal Harworth; and Mary (b. 1510), who married Thomas Stanley, Lord Monteagle. By Mary Tudor he had Henry earl of Lincoln (1516–1634); Frances, who married Henry Grey, marquess of Dorset, and became the mother of Lady Jane Grey; and Eleanor, who married Henry Clifford, second earl of Cumberland. By Katherine Willoughby he had two sons who showed great promise, Henry (1535–1551) and Charles (*c.* 1537–1551), dukes of Suffolk. They died of the sweating sickness within an hour of one another. Their tutor, Sir Thomas Wilson, compiled a memoir of them, *Vita et obitus duorum fratrum Suffolcensium* (1551).

There is abundant material for the history of Suffolk's career in the *Letters and Papers of Henry VIII.* (ed. Brewer in the Rolls Series). See also Dugdale, *Baronage of England* (vol. ii. 1676); and G. E. C., *Complete Peerage.* An account of his matrimonial adventures is in the historical appendix to a novel by E. S. Holt entitled *The Harvest of Yesterday.*

SUFFOLK, THOMAS HOWARD, 1ST EARL OF (1561–1626), second son of Thomas Howard, 4th duke of Norfolk, was born on the 24th of August 1561. He behaved very gallantly during the attack on the Spanish armada and afterwards took part in other naval expeditions, becoming an admiral in 1599. Created Baron Howard de Walden in 1597 and earl of Suffolk in July 1603, he was lord chamberlain of the royal household from 1603 to 1614 and lord high treasurer from 1614 to 1618, when he was deprived of his office on a charge of misappropriating money. He was tried in the Star-chamber and was sentenced to pay a heavy fine. Suffolk's second wife was Catherine (d. 1633), widow of the Hon. Richard Rich, a woman whose avarice was partly responsible for her husband's downfall. She shared his trial and was certainly guilty of taking bribes from Spain. One of his three daughters was the notorious Frances Howard, who, after obtaining a divorce from her first husband, Robert Devereux, earl of Essex, married Robert Carr, earl of Somerset, and instigated the poisoning of Sir Thomas Overbury. The earl died on the 28th of May 1626. He built a magnificent residence at Audley End, Essex, which is said to have cost £200,000. One of Suffolk's seven sons was Sir Robert Howard (1585–1653), who inherited Clun Castle, Shropshire, on the death of his brother, Sir Charles Howard, in 1622. He was twice imprisoned on account of his illicit relations with Frances; Viscountess Purbeck (d. 1645), a daughter of Sir Edward Coke, and after sitting in six parliaments was expelled from the House of Commons for executing the king's commission of array in 1642. He died on the 22nd of April 1653. Another of Suffolk's sons, Edward (d. 1675), was created baron Howard of Escrick in 1628. He was one of the twelve peers who signed the petition on grievances, which he presented to Charles I. at York in 1640, and after the abolition of the House of Lords in 1649 he sat in the House of Commons as member for Carlisle, being also a member of the council of state. In 1651 he was expelled from parliament for taking bribes and he died on the 24th of April 1675. His second son, William, 3rd lord Howard of Escrick (*c.* 1626–1694), was a member of the republican party during the Commonwealth; later he associated himself with the opponents of the arbitrary rule of Charles II., but turning informer he was partly responsible for the conviction of Lord William Russell and of Algernon Sydney in 1683. On the death of William's son, Charles, the 4th lord, in 1715 the barony of Howard of Escrick became extinct.

Suffolk's eldest son, THEOPHILUS, 2nd earl of Suffolk (1584–1640), was captain of the band of gentlemen pensioners under James I. and Charles I., and succeeded to the earldom in May 1626, obtaining about the same time some of the numerous offices which had been held by his father, including the lord-lieutenancy of the counties of Suffolk, Cambridge and Dorset. He died on the 3rd of June 1640, when his eldest son James (1619–1689) became 3rd earl. This nobleman, who acted as earl marshal of England at the coronation of Charles II., died in January 1689 when his barony of Howard de Walden fell into abeyance between his two daughters.[1] His earldom, however, passed to his brother George (*c.* 1625–1691), who

[1] Having thus fallen into abeyance in 1689 the barony of Howard de Walden was revived in 1784 in favour of John Griffin Griffin, afterwards Lord Braybrooke, on whose death in May 1797 it fell again into abeyance. In 1799 the bishop of Derry, Frederick Augustus Hervey, 4th earl of Bristol, a descendant of the 3rd earl of Suffolk, became the sole heir to the barony. On Bristol's death in July 1803 it passed to Charles Augustus Ellis (1799–1868), a grandson of the bishop's elder son, John Augustus, Lord Hervey (1757–1796), who had predeceased his father. It was thus separated from the marquessate of Bristol, which passed to the bishop's only surviving son, and it has since been held by the family of Ellis.

became 4th earl of Suffolk. George's nephew, Henry, the 6th earl (*c.* 1670–1718), who was president of the board of trade from 1715 to 1718, left an only son, Charles William (1693–1722), who was succeeded in turn by his two uncles, the younger of them, Charles (1675–1733) becoming 9th earl on the death of his brother Edward in June 1731. This earl was the husband of Henrietta countess of Suffolk (*c.* 1681–1767), the mistress of George II., who was a daughter of Sir Henry Hobart, bart., of Blickling, Norfolk. When still the Hon. Charles Howard, he and his wife made the acquaintance of the future king in Hanover; after the accession of George I. to the English throne in 1714 both husband and wife obtained posts in the household of the prince of Wales, who, when he became king as George II., publicly acknowledged Mrs Howard as his mistress. She was formally separated from her husband before 1731 when she became countess of Suffolk. The earl died on the 28th of September 1733, but the countess, having retired from court and married the Hon. George Berkeley (d. 1746), lived until the 26th of July 1767. Among Lady Suffolk's friends were the poets Pope and Gay and Charles Mordaunt (earl of Peterborough).

A collection of *Letters to and from Henrietta Countess of Suffolk, and her Second Husband, the Hon. George Berkeley*, was edited by J. W. Croker (1824).

The 9th earl's only son Henry, the 10th earl (1706–1745), died without sons in April 1745, when his estate at Audley End passed to the descendants of the 3rd earl, being inherited in 1762 by John Griffin Griffin (1719–1797), afterwards Lord Howard de Walden and Lord Braybrooke. As owners of this estate the earls of Suffolk of the Howard line had hitherto been hereditary visitors of Magdalene College, Cambridge, but this office now passed away from them. The earldom of Suffolk was inherited by Henry Bowes Howard, 4th earl of Berkshire (1696–1757), who was the great-grandson of Thomas Howard (*c.* 1590–1669), the second son of the 1st earl of Suffolk, Thomas having been created earl of Berkshire in 1626. Since 1745 the two earldoms have been united, Henry Molyneux Paget Howard (b. 1877) succeeding his father, Henry Charles (1833–1898), as 19th earl of Suffolk and 12th earl of Berkshire in 1898.

SUFFOLK, WILLIAM DE LA POLE, Duke of (1396–1450), second son of Michael de la Pole, second earl of Suffolk, was born on the 16th of October 1396. His father died at the siege of Harfleur, and his elder brother was killed at Agincourt on the 25th of October 1415. Suffolk served in all the later French campaigns of the reign of Henry V., and in spite of his youth held high command on the marches of Normandy in 1421–22. In 1423 he joined the earl of Salisbury in Champagne, and shared his victory at Crévant. He fought under John, duke of Bedford, at Verneuil on the 17th of August 1424, and throughout the next four years was Salisbury's chief lieutenant in the direction of the war. When Salisbury was killed before Orleans on the 3rd of November 1428, Suffolk succeeded to the command. After the siege was raised, Suffolk was defeated and taken prisoner by Jeanne d'Arc at Jargeau on the 12th of June 1429. He was soon ransomed, and during the next two years was again in command on the Norman frontier. He returned to England in November 1431, after over fourteen years' continuous service in the field.

Suffolk had already been employed on diplomatic missions by John of Bedford, and from this time forward he had an important share in the work of administration. He attached himself naturally to Cardinal Beaufort, and even thus early seems to have been striving for a general peace. But public opinion in England was not yet ripe, and the unsuccessful conference at Arras, with the consequent defection of Burgundy, strengthened the war party. Nevertheless the cardinal's authority remained supreme in the council, and Suffolk, as his chief supporter, gained increasing influence. The question of Henry VI.'s marriage brought him to the front. Humphrey of Gloucester favoured an Armagnac alliance. Suffolk brought about the match with Margaret of Anjou. Report already represented Suffolk as too friendly with French leaders like Charles of Orleans, and it was with reluctance that he undertook the responsibility of an embassy to France. However, when he returned to England in June 1444, after negotiating the marriage and a two years' truce, he received a triumphant reception. He was made a marquess, and in the autumn sent again to France to bring Margaret home. The French contrived to find occasion for extorting a promise to surrender all the English possessions in Anjou and Maine, a concession that was to prove fatal to Suffolk and his policy. Still for the time his success was complete, and his position as the personal friend of the young king and queen seemed secure. Humphrey of Gloucester died in February 1447, within a few days of his arrest, and six weeks later Cardinal Beaufort died also. Suffolk was left without an obvious rival, but his difficulties were great. Rumour, though without sufficient reason, made him responsible for Humphrey's death, while the peace and its consequent concessions rendered him unpopular. So also did the supersession of Richard of York by Edmund Beaufort, duke of Somerset, in the French command. Suffolk's promotion to a dukedom in July 1448, marked the height of his power. The difficulties of his position may have led him to give some countenance to a treacherous attack on Fougéres during the time of truce (March 1449). The renewal of the war and the loss of all Normandy were its direct consequences. When parliament met in November 1449, the opposition showed its strength by forcing the treasurer, Adam Molyneux, to resign. Molyneux was murdered by the sailors at Portsmouth on the 9th of January 1450. Suffolk, realizing that an attack on himself was inevitable, boldly challenged his enemies in parliament, appealing to the long and honourable record of his public services. On the 7th of February and again on the 9th of March the Commons presented articles of accusation dealing chiefly with alleged maladministration and the ill success of the French policy; there was a charge of aiming at the throne by the betrothal of his son to the little Margaret Beaufort, but no suggestion of guilt concerning the death of Gloucester. The articles were in great part baseless, if not absurd. Suffolk, in his defence on the 13th of March, denied them as false, untrue and too horrible to speak more of. Ultimately, as a sort of compromise, the king sentenced him to banishment for five years. Suffolk left England on the 1st of May. He was intercepted in the Channel by the ship "Nicholas of the Tower," and next morning was beheaded in a little boat alongside. The "Nicholas" was a royal ship, and Suffolk's murder was probably instigated by his political opponents.

Popular opinion at the time judged Suffolk as a traitor. This view was accepted by Yorkist chroniclers and Tudor historians, who had no reason to speak well of a Pole. Later legend made him the paramour of Margaret of Anjou. Though utterly baseless, the story gained currency in the *Mirrour for Magistrates*, and was adopted in Shakespeare's *2 Henry VI.* (act III. sc. ii.). Suffolk's best defence is contained in the touching letter of farewell to his son, written on the eve of his departure (*Paston Letters*, i. 142), and in his noble speeches before parliament (*Rolls of Parliament*, v. 176, 182). Of the former Lingard said well that it is "difficult to believe that the writer could have been either a false subject or a bad man." The policy of peace which Suffolk pursued was just and wise; he foresaw from the first the personal risk to which its advocacy exposed him. This alone should acquit him of any base motive; his conduct was "throughout open and straightforward" (Stubbs). Whatever his defects as a statesman, he was a gallant soldier, a man of culture and a loyal servant.

Suffolk's wife, Alice, was widow of Thomas, earl of Salisbury, and granddaughter of Geoffrey Chaucer. By her he had an only son John, second duke of Suffolk.

Bibliography.—Suffolk is necessarily prominent in all contemporary authorities. The most important are J. Stevenson's *Wars of the English in France*, Thomas Beckington's *Correspondence*, T. Wright's *Political Poems and Songs*, ii. 222–234 (for the popular view)—these three are in the Rolls Series; and the *Paston Letters*. Of French writers E. de Monstrelet and Jehan de Waurin are most useful for his military career, T. Basin and Matthieu d'Escouchy for his fall (all these are published by the Société de l'Histoire de

France). For modern accounts see especially W. Stubbs, *Constitutional History* (favourable), *The Political History of England* (1906), vol. iv., by C. Oman (unfavourable), and G. du Fresne de Beaucourt's *Histoire de Charles VII*. See also H. A. Napier's *Historical Notices of Swincombe and Ewelme* (1858). (C. L. K.)

SUFFOLK, an eastern county of England, bounded N. by Norfolk, E. by the North Sea, S. by Essex and W. by Cambridgeshire. The area is 1488·6 sq. m. The surface is as a whole but slightly undulating. In the extreme north-west near Mildenhall, a small area of the Fen district is included. This is bordered by a low range of chalk hills extending from Haverhill northwards along the western boundary, and thence by Bury St Edmunds to Thetford. The coast-line has a length of about 62 m., and is comparatively regular, the bays being generally shallow and the headlands rounded and only slightly prominent. The estuaries of the Deben, Orwell and Stour, however, are between 10 and 12 m. in length. The shore is generally low and marshy, with occasional clay and sand cliffs. It includes, in the declivity on which Old Lowestoft stands, the most easterly point of English land. Like the Norfolk coast, this shore has suffered greatly from incursions of the sea, the demolition of the ancient port of Dunwich (*q.v.*) forming the most noteworthy example. The principal seaside resorts are Lowestoft, Southwold, Aldeburgh and Felixstowe. The rivers flowing northward are the Lark, in the north-west corner, which passes in a north-westerly direction to the Great Ouse in Norfolk; the Little Ouse or Brandon, also a tributary of the Great Ouse, flowing by Thetford and Brandon and forming part of the northern boundary of the county; and the Waveney, which rises in Norfolk and forms the northern boundary of Suffolk from Palgrave till it falls into the mouth of the Yare at Yarmouth. The Waveney is navigable from Bungay, and by means of Oulton Broad also communicates with the sea at Lowestoft. The rivers flowing in a south-easterly direction to the North Sea are the Blyth; the Alde or Ore, which has a course for nearly 10 m. parallel to the seashore; the Deben, from Debenham, flowing past Woodbridge, up to which it is navigable; the Orwell or Gipping, which becomes navigable at Stowmarket, whence it flows past Needham Market and Ipswich; and the Stour, which forms nearly the whole southern boundary of the county, receiving the Brett, which flows past Lavenham and Hadleigh; it is navigable from Sudbury. At the union of its estuary with that of the Orwell is the important port of Harwich (in Essex). The county has no valuable minerals. Flints are worked, as they have been from pre-historic times; a considerable quantity of clay is raised and lime and whiting are obtained in various districts.

Geology.—The principal geological formations are the Chalk and the Tertiary deposits. The former occupies the surface, except where covered by superficial drift, in the central and north-west portions of the county, and it extends beneath the Tertiaries in the south-east and east. In the extreme north-west round Mildenhall the Chalk borders a tract of fen land in a range of low hills from Haverhill by Newmarket and Bury St Edmunds to Thetford. The Chalk is quarried near Ipswich, Bury St Edmunds, Mildenhall and elsewhere; at Brandon the chalk flints for gun-locks and building have been exploited from early times. The Tertiary formations include Thanet sand, seen near Sudbury; and Reading Beds and London Clay which extend from Sudbury through Hadleigh, Ipswich, Woodbridge and thence beneath younger deposits to the extreme north-east of the county. Above the Eocene formations lie the Pliocene "Crags," which in the north overlap the Eocene boundary on to the chalk. The oldest of the crag deposits is the Coralline Crag, pale sandy and marly beds with many fossils; this is best exposed west and north of Aldeburgh and about Sudbourne and Orford. Resting upon the Coralline beds, or upon other formations in their absence, is the Red Crag, a familiar feature above the London Clay in the cliffs at Felixstowe and Baudsey, where many fossils used to be found; inland it appears at Bentley, Stutton and Chillesford, where the "Scrobicularia Clay" and Chillesford beds of Prestwich appear above it. The last-named beds probably correspond with the Norwich Crag, the name given to the upper, paler portion of the Red Crag, together with certain higher beds in the north part of east Suffolk. The Norwich Crag is visible at Dunwich, Bavent, Easton and Wangford. In the north the Cromer Forest beds, gravels with fresh-water fossils and mammalian remains, may be seen on the coast at Corton and Pakefield. Between the top of the London Clay and the base of the Crags is the "Suffolk Bone Bed" with abundant mammalian bones and phosphatic nodules. Glacial gravel, sand and chalky boulder clay are scattered over much of the county, generally forming stiffer soils in the west and lighter sandy soils in the east. Pebble gravels occur at Westleton and Halesworth, and later gravels, with palaeolithic implements, at Hoxne; while old river-gravels of still later date border the present river valleys. The chalk and gault have been penetrated by a boring at Stutton, revealing a hard palaeozoic slaty rock at the depth of about 1000 ft.

Agriculture.—Suffolk is one of the most fertile counties in England. In the 18th century it was famed for its dairy products. The high prices of grain during the wars of the French Revolution led to the extensive breaking up of its pastures, and it is now one of the principal grain-growing counties in England. There is considerable variety of soils, and consequently in modes of farming in different parts of the county. Along the sea-coast a sandy loam or thin sandy soil prevails, covered in some places with the heath on which large quantities of sheep are fed, interspersed with tracts, more or less marshy, on which cattle are grazed. The best land adjoins the rivers, and consists of a rich sandy loam, with patches of lighter and easier soil. In the south-west and the centre is much finer grain-land having mostly a clay subsoil, but not so tenacious as the clay in Essex. In climate Suffolk is one of the driest of the English counties; thus, the mean annual rainfall at Bury St Edmunds is rather less than 24 in. Towards the north-west the soil is generally poor, consisting partly of sand on chalk, and partly of peat and open heath. Some four-fifths of the total area of the county is under cultivation. Barley, oats and wheat are the most important of the grain crops. The breed of horses known as Suffolk punches is one of the most valued for agricultural purposes in England. The breed of cattle native to the county is a polled variety, on the improvement of which great pains have been bestowed. The old Suffolk cows, famous for their great milking qualities, were of various colours, yellow predominating. The improved are all red. Much milk is sent to London, Yarmouth, &c. Many cattle, mostly imported from Ireland, are grazed in the winter. The sheep are nearly all of the blackfaced improved Suffolk breed, a cross between the old Norfolk horned sheep and Southdowns. The breed of pigs most common is small and black.

Manufactures and Trade.—The county is essentially agricultural, and the most important manufactures relate to this branch of industry. They include that of agricultural implements, especially at Ipswich, Bury St Edmunds and Stowmarket, and that of artificial manures at Ipswich and Stowmarket, for which coprolites are dug. Malting is extensively carried on throughout the county. There are chemical and gun-cotton manufactories at Stowmarket and gun flints are still made at Brandon. At other towns small miscellaneous manufactures are carried on, including silk, cotton, linen, woollen, and horsehair and coco-nut matting. The principal ports are Lowestoft, Southwold, Aldeburgh, Woodbridge and Ipswich. Lowestoft is the chief fishing town. Herrings and mackerel are the fish most abundant on the coasts.

Communications.—The main line of the Great Eastern railway, entering the county from the south, serves Ipswich and Stowmarket, continuing north into Norfolk. The east Suffolk branch from Ipswich serves Woodbridge, Saxmundham, Halesworth, and Beccles, with branches to Felixstowe, to Framlingham, to Aldeburgh, and to Lowestoft; while the Southwold Light railway connects with that town from Halesworth. The other principal branches are those from Stowmarket to Bury St Edmunds and westward into Cambridgeshire, from Essex into Norfolk by Long Melford, Bury St Edmunds and Thetford, and from Long Melford to Haverhill, which is the northern terminus of the Colne Valley railway.

Population and Administration.—The area of the ancient county is 952,710 acres, with a population in 1891 of 371,235 and in 1901 of 384,293. Suffolk comprises 21 hundreds, and for administrative purposes is divided into the counties of East Suffolk (557,854 acres) and West Suffolk (390,914 acres). The following are municipal boroughs and urban districts.

(1) EAST SUFFOLK. Municipal boroughs—Aldeburgh (pop. 2405), Beccles (6898), Eye (2004), Ipswich, a county borough and the county town (66,630), Lowestoft (29,850), Southwold (2800). Urban districts—Bungay (3314), Felixstowe and Walton (5815), Halesworth (2246), Leiston-cum-Sizewell (3259), Oulton Broad (4044), Saxmundham (1452), Stowmarket (4162), Woodbridge (4640).

(2) WEST SUFFOLK. Municipal boroughs—Bury St Edmunds (16,255), Sudbury (7109). Urban districts—Glemsford (1975), Hadleigh (3245), Haverhill (4862), Newmarket (10,688), which is mainly in the ancient county of Cambridge.

Small market and other towns are numerous, such are Brandon, Clare, Debenham, Framlingham, Lavenham, Mildenhall, Needham Market and Orford. For parliamentary purposes the county constitutes five divisions, each returning one member, viz. north or Lowestoft division, north-east or Eye, north-west or Stowmarket, south or Sudbury, and south-east or Woodbridge. Bury St Edmunds returns one member and Ipswich two; part of the borough of Great Yarmouth falls within the county. There is one court of quarter sessions for the two administrative counties, which is usually held at Ipswich for east Suffolk, and then by adjournment at Bury St Edmunds for west Suffolk. East Suffolk is divided into 11 and west Suffolk into 8 petty sessional divisions. The boroughs of Bury St Edmunds, Ipswich, Sudbury, Eye, Lowestoft and Southwold have separate commissions of the peace, and the three first-named have also separate courts of quarter sessions. The total number of civil parishes is 519. The ancient county contains 465 ecclesiastical parishes and districts, wholly or in part; it is situated partly in the diocese of Ely and partly in that of Norwich.

History.—The county of Suffolk (Sudfole, Suthfolc) was formed from the south part of the kingdom of East Anglia which had been settled by the Angles in the latter half of the 5th century. The most important Anglo-Saxon settlements appear to have been made at Sudbury and Ipswich. Before the end of the Norman dynasty strongholds had arisen at Eye, Clare, Walton and Framlingham. Probably the establishment of Suffolk as a separate shire was scarcely completed before the Conquest, and although it was reckoned as distinct from Norfolk in the Domesday Survey of 1086, the fiscal administration of Norfolk and Suffolk remained under one sheriff until 1575. The boundary of the county has undergone very little change, though its area has been considerably affected by coast erosion. Parts of Gorleston and Thetford, which formerly belonged to the ancient county of Suffolk, are now within the administrative county of Norfolk, and other slight alterations of the administrative boundary have been made. Under the Local Government Act of 1888 Suffolk was divided into the two administrative counties of east and west Suffolk.

At first the whole shire lay within the diocese of Dunwich which was founded *c.* 631. In 673 a new bishopric was established at Elmham to comprise the whole of Norfolk which had formerly been included in the see of Dunwich. The latter came to an end with the incursion of the Danes, and on the revival of Christianity in this district Suffolk was included in the diocese of Elmham, subsequently removed from South Elmham to Thetford and thence to Norwich. In 1835–1836 the archdeaconry of Sudbury was transferred by the ecclesiastical commissioners to the diocese of Ely. This archdeaconry had been separated from the original archdeaconry of Suffolk in 1127. In 1256 the latter included thirteen deaneries which have since been subdivided, so that at present it contains eighteen deaneries; Sudbury archdeaconry which comprised eight deaneries in 1256 now includes eleven. There were also three districts under peculiar jurisdiction of Canterbury and one under that of Rochester.

The shire-court was held at Ipswich. In 1831 the whole county contained twenty-one hundreds and three municipal boroughs. Most of these hundreds were identical with those of the Domesday Survey, but in 1086 Babergh was rated as two hundreds, Cosford, Ipswich and Parham as half hundreds and Samford as a hundred and a half. Hoxne hundred was formerly known as Bishop's hundred and the vills which were included later in Thredling hundred were within Claydon hundred in 1086. Two large ecclesiastical liberties extended over more than half of the county; that of St Edmund included the hundreds of Risbridge, Thedwastry, Thingoe, Cosford, Lackford and Blackbourn in which the king's writ did not run, and St Aethelreda of Ely claimed a similar privilege in the hundreds of Carleford, Colneis, Plumesgate, Loes, Wilford and Thredling. Among others who had large lands in the county with co-extensive jurisdiction were the lords of the honor of Clare, earls of Gloucester and Hereford and the lords of the honor of Eye, held successively by the Bigods, the Uffords and the De la Poles, earls of Suffolk. The Wingfields, Bacons and Herveys have been closely connected with the county.

Suffolk suffered severely from Danish incursions, and after the Treaty of Wedmore became a part of the Danelagh. In 1173 the earl of Leicester landed at Walton with an army of Flemings and was joined by Hugh Bigod against Henry II. In 1317 and the succeeding years a great part of the county was in arms for Thomas of Lancaster. Queen Isabella and Mortimer having landed at Walton found all the district in their favour. In 1330 the county was raised to suppress the supporters of the earl of Kent; and again in 1381 there was a serious rising of the peasantry chiefly in the neighbourhood of Bury St Edmunds. Although the county was for the most part Yorkist it took little part in the Wars of the Roses. In 1525 the artisans of the south strongly resisted Henry VIII.'s forced loan. It was from Suffolk that Mary drew the army which supported her claim to the throne. In the Civil Wars the county was for the most part parliamentarian, and joined the Association of the Eastern Counties for defence against the Papists.

The county was constantly represented in parliament by two knights from 1290, until the Reform Bill of 1832 gave four members to Suffolk, at the same time disfranchising the boroughs of Dunwich, Orford and Aldeburgh. Suffolk was early among the most populous of English counties, doubtless owing to its proximity to the continent. Fishing fleets have left its ports to bring back cod and ling from Iceland and herring and mackerel from the North Sea. From the 14th to the 17th century it was among the chief manufacturing counties of England owing to its cloth-weaving industry, which was at the height of its prosperity during the 15th century. In the 17th and 18th centuries its agricultural resources were utilized to provide the rapidly-growing metropolis with food. In the following century various textile industries, such as the manufacture of sail-cloth, cocoa-nut fibre, horse-hair and clothing were established; silk-weavers migrated to Suffolk from Spitalfields, and early in the 19th century an important china factory flourished at Lowestoft.

Antiquities.—Of monastic remains the most important are those of the great Benedictine abbey of Bury St Edmunds, noticed under that town; the college of Clare, originally a cell to the abbey of Bec in Normandy and afterwards to St Peter's Westminster, converted into a college of secular canons in the reign of Henry VI., still retaining much of its ancient architecture, and now used as a boarding-school; the Decorated gateway of the Augustinian priory of Butley; and the remains of the Grey Friars monastery at Dunwich. A peculiarity of the church architecture is the use of flint for purposes of ornamentation, often of a very elaborate kind, especially on the porches and parapets of the towers. Another characteristic is the round towers, which are confined to East Anglia, but are considerably more numerous in Norfolk than in Suffolk, the principal being those of Little Saxham and Herringfleet, both good examples of Norman. It is questionable whether there are any remains of pre-Norman architecture in the county. The Decorated is well represented, but by far the greater proportion of the churches are Perpendicular, fine examples of which are so numerous that it is hard to select examples. But the church of Blythburgh in the east and the exquisite ornate building at Lavenham in the west may be noted as typical, while the church of Long Melford, another fine example, should be mentioned on account of its remarkable lady chapel. Special features are the open roofs and woodwork (as at St Mary's, Bury St Edmunds, Earl Stonham and Stonham Aspall, Ufford and Blythburgh), and the fine fonts.

The remains of old castles are comparatively unimportant, the principal being the entrenchments and part of the walls of Bungay, the ancient stronghold of the Bigods; the picturesque ruins of Mettingham, built by John de Norwich in the reign of Edward III.; Wingfield, surrounded by a deep moat, with the turret walls and the drawbridge still existing; the splendid ruin of Framlingham, with high and massive walls, originally founded in the 6th century, but restored in the 12th; the outlines of the extensive fortress of Clare Castle, anciently the baronial residence of the earls of Clare; and the fine Norman keep of Orford Castle, on an eminence overlooking the sea. Among the many fine residences within the county there are several interesting examples of domestic architecture of the reigns of Henry VIII. and Elizabeth. Hengrave Hall (*c.* 1530), 4 m. north-west from Bury St Edmunds, is a noteworthy example—an exceedingly picturesque building of brick and stone, enclosing a court-yard. Another is Helmingham Hall, a Tudor mansion of brick, surrounded by a moat crossed by a drawbridge. West Stow Manor is also Tudor; its gatehouse is fine, but the mansion has been adapted into a farmhouse.

See A. Suckling, *The History and Antiquities of Suffolk* (1846–1848); William White, *History, gazetteer and directory of Suffolk* (1855); John Kirby, *The Suffolk Traveller* (1735); A. Page, *Supplement to the Suffolk Traveller* (1843); *Victoria County History; Suffolk.*

SUFFRAGAN (Med. Lat. *suffraganeus suffragator*, one who assists, from *suffragari*, to vote in favour of, to support) in the Christian Church, (1) a diocesan bishop in his relation to the metropolitan; (2) an assistant bishop. (See the article Bishop.)

SUFFRAGE (Lat. *suffragium*), the right or the exercise of the right of voting in political affairs; in a more general sense, an expression of opinion, assent or approval; in ecclesiastical use, the short intercessory prayers in litanies spoken or sung by the people as distinguished from those of the priest or minister. (See REPRESENTATION; VOTE AND VOTING, and REGISTRATION: and, for the Women's Suffrage Movement, WOMEN: § *Political Rights.*) The etymology of the Latin word *suffragium* has been much discussed. It is usually referred to *sub-* and the root of *frangere*, to break, and its original meaning must thus have been a piece of broken tile or a potsherd on which the names or initials of the candidates were inscribed and used as a voting tablet or *tabella*. There is, however, no direct evidence that this was ever the practice in the case of voting upon legislation in the assembly (see W. Corssen, *Ueber Aussprache*, &c., *der Lateinischen Sprache*, i. 397, and Mommsen, *Römische Geschichte*, iii. 412 n. i.).

SUFFREN SAINT TROPEZ, PIERRE ANDRÉ DE (1729–1788), French admiral, was the third son of the marquis de Saint Tropez, head of a family of nobles of Provence which claimed to have emigrated from Lucca in the 14th century. He was born in the Château de Saint Canat in the present department of Aix on the 17th of July 1729. The French navy and the Order of Malta offered the usual careers for the younger sons of noble families of the south of France who did not elect to go into the Church. The connexion between the Order and the old French royal navy was close. Pierre André de Suffren was destined by his parents to belong to both. He entered the close and aristocratic corps of French naval officers as a "garde de la marine"—cadet or midshipman, in October 1743, in the "Solide," one of the line of battleships which took part in the confused engagement off Toulon in 1744. He was then in the "Pauline" in the squadron of M. Macnémara on a cruise in the West Indies. In 1746 he went through the duc D'Anville's disastrous expedition to retake Cape Breton, which was ruined by shipwreck and plague. Next year (1747) he was taken prisoner by Hawke in the action with the French convoy in the Bay of Biscay. His biographer Cunat assures us that he found British arrogance offensive. When peace was made in 1748 he went to Malta to perform the cruises with the galleys of the Order technically called "caravans," a reminiscence of the days when the knights protected the pilgrims going from Saint John d'Acre to Jerusalem. In Suffren's time this service rarely went beyond a peaceful tour among the Greek islands. During the Seven Years' War he had the unwonted good fortune to be present as lieutenant in the "Orphée" in the action with Admiral Byng (*q.v.*), which, if not properly speaking a victory, was at least not a defeat for the French, and was followed by the surrender of the English garrison of Minorca. But in 1757 he was again taken prisoner, when his ship the "Océan" was captured by Boscawen off Lagos. On the return of peace in 1763 he intended again to do the service in the caravans which was required to qualify him to hold the high and lucrative posts of the Order. He was, however, named to the command of the "Caméléon," a zebec—a vessel of mixed square and lateen rig peculiar to the Mediterranean—in which he cruised against the pirates of the Barbary coast. Between 1767 and 1771 he performed his caravans, and was promoted from knight to commander of the Order. From that time till the beginning of the War of American Independence he commanded vessels in the squadron of evolution which the French government had established for the purpose of giving practice to its officers. His nerve and skill in handling his ship were highly commended by his chiefs. In 1778 and 1779 he formed part of the squadron of D'Estaing (*q.v.*) throughout its operations on the coast of North America and in the West Indies. He led the line in the action with Admiral John Byron off Grenada, and his ship, the "Fantasque" (64), lost 62 men. His letters to his admiral show that he strongly disapproved of D'Estaing's half-hearted methods. In 1780 he was captain of the "Zèle" (74), in the combined French and Spanish fleets which captured a great English convoy in the Atlantic. His candour towards his chief had done him no harm in the opinion of D'Estaing. It is said to have been largely by the advice of this admiral that Suffren was chosen to command a squadron of five ships of the line sent out to help the Dutch who had joined France and Spain to defend the Cape against an expected English attack, and then to go on to the East Indies. He sailed from Brest on the 22nd of March on the cruise which has given him a unique place among French admirals, and puts him in the front rank of sea commanders. He was by nature even more vehement than able. The disasters which had befallen the navy of his country during the last two wars, and which, as he knew, were due to bad administration and timid leadership, had filled him with a burning desire to retrieve its honour. He was by experience as well as by temperament impatient with the formal manœuvring of his colleagues, which aimed at preserving their own ships rather than at taking the English, and though he did not dream of restoring the French power in India, he did hope to gain some such success as would enable his country to make an honourable peace. On the 16th of April 1781 he found the English expedition on its way to the Cape under the command of Commodore, commonly called Governor, George Johnstone (1730–1787), at anchor in Porto Praya, Cape de Verd Islands. Remembering how little respect Boscawen had shown for the neutrality of Portugal at Lagos, he attacked at once. Though he was indifferently supported, he inflicted as much injury as he suffered, and proved to the English that in him they had to deal with an admiral of quite a different type from the Frenchmen they had been accustomed to as yet. He pushed on to the Cape, which he saved from capture by Johnstone, and then made his way to the Isle de France (Mauritius), then held by the French. M. D'Orves, his superior officer, died as the united squadrons, now eleven sail of the line, were on their way to the Bay of Bengal. The campaign, which Suffren now conducted against the English admiral Sir Edward Hughes (1720?–1794), is famous for the number and severity of the encounters between them. Four actions took place in 1782: on the 17th of February 1782, south of Madras; on the 12th of April near Trincomalee; on the 6th of July off Cuddalore, after which Suffren seized upon the anchorage of Trincomalee compelling the small British garrison to surrender; and again near that port on the 3rd of September. No ship was lost by Sir Edward Hughes in any of these actions, but none were taken by him. Suffren attacked with unprecedented vigour on every occasion, and if he had not been ill-supported by some of his captains he would undoubtedly have gained a distinct victory; as it was, he maintained his squadron without the help of a port to refit, and provided himself with an anchorage at Trincomalee. His activity encouraged Hyder Ali, who was then at war with the Company. He refused to return to the islands for the purpose of escorting the troops coming out under command of Bussy, maintaining that his proper purpose was to cripple the squadron of Sir Edward Hughes. During the north-east monsoon he would not go to the islands but refitted in the Malay ports in Sumatra, and returned with the south-west monsoon in 1783. Hyder Ali was dead, but Tippoo Sultan, his son, was still at war with the Company. Bussy arrived and landed. The operations on shore were slackly conducted by him, and Suffren was much hampered, but when he fought his last battle against Hughes (April 20, 1783), with fourteen ships to eighteen he forced the English admiral to retire to Madras, leaving the army then besieging Cuddalore in a very dangerous position. The arrival of the news that peace had been made in Europe put a stop to hostilities, and Suffren returned to France. While refitting at the Cape on his way home, several of the vessels also returning put in, and the captains waited on him. Suffren said in one of his letters that their praise gave him more pleasure than any other compliment paid him. In France he was received with enthusiasm, and an additional office of vice-admiral of France was created for him. He had been promoted bailli in the Order of Malta during his absence. His death occurred very suddenly on the 8th of December 1788, when he was about to take command of a fleet collected in Brest. The official version of the cause of death was apoplexy, and as he was a very corpulent man it appeared plausible. But many years afterwards his body servant told M. Jal, the historiographer of the French navy, that he had been killed in a duel by the prince de Mirepoix. The cause of the encounter, according to the servant, was that Suffren had refused in very strong language to use his influence to secure the restoration to the navy of two of the prince's relations who had been dismissed for misconduct.

Suffren was crippled to a large extent by the want of loyal and capable co-operation on the part of his captains, and the vehemence of his own temperament sometimes led him to disregard prudence, yet he had an indefatigable energy, a wealth of resource, and a thorough understanding of the fact—so habitually disregarded by French naval officers—that success at sea is won by defeating an enemy and not by merely outmanœuvring him; and this made him a most formidable enemy. The portraits of Suffren usually reproduced are worthless, but there is a good engraving by Mme de Cernel after an original by Gérard.

The standard authority for the life of Suffren is the *Histoire du Bailli de Suffren* by Ch. Cunat (1852). The *Journal de Bord du Bailli de Suffren dans l'Inde*, edited by M. Mores, was published in 1888. There is an appreciative study in Captain Mahan's *Sea Power in History*. (D. H.)

ṢŪFIISM (*taṣawwuf*), a term used by Moslems to denote any variety of mysticism, is formed from the Arabic word *Ṣūfī*, which was applied, in the 2nd century of Islam, to men or women who adopted an ascetic or quietistic way of life. There can be no doubt that *Ṣūfī* is derived from *ṣūf* (wool) in reference to the woollen garments often, though not invariably, worn by such persons: the phrase *labisa's-ṣūf* ("he clad himself in wool") is commonly used in this sense, and the Persian word *pashmīna-pūsh*, which means literally "clothed in a woollen garment," is synonymous with *Ṣūfī*. Other etymologies, such as *Ṣafā* (purity)—a derivation widely accepted in the East—and σοφός, are open to objection on linguistic grounds.

In order to trace the origin and history of mysticism in Islam we must go back to Mahomet. On one side of his nature the Prophet was an ascetic and in some degree a mystic. Notwithstanding his condemnation of Christian monkery (*rahbānīya*), *i.e.* of celibacy and the solitary life, the example of the Ḥanīfs, with some of whom he was acquainted, and the Christian hermits made a deep impression on his mind and led him to preach the efficacy of ascetic exercises, such as prayer, vigils and fasting. Again, while Allah is described in the Koran as the One God working his arbitrary will in unapproachable supremacy, other passages lay stress on his all-pervading presence and intimate relation to his creatures, *e.g.* "Wherever ye turn, there is the face of Allah" (ii. 109), "We (God) are nearer to him (Man) than his neck-vein" (l. 15). The germs of mysticism latent in Islam from the first were rapidly developed by the political, social and intellectual conditions which prevailed in the two centuries following the Prophet's death. Devastating civil wars, a ruthless military despotism caring only for the things of this world, Messianic hopes and presages, the luxury of the upper classes, the hard mechanical piety of the orthodox creed, the spread of rationalism and freethought, all this induced a revolt towards asceticism, quietism, spiritual feeling and emotional faith. Thousands, wearied and disgusted with worldly vanities, devoted themselves to God. The terrors of hell, so vividly depicted in the Koran, awakened in them an intense consciousness of sin, which drove them to seek salvation in ascetic practices. Ṣūfiism was originally a practical religion, not a speculative system; it arose, as Junayd of Bagdad says, "from hunger and taking leave of the world and breaking familiar ties and renouncing what men deem good, not from disputation." The early Ṣūfīs were closely attached to the Mahommedan church. It is said that Abū Hāshim of Kūfa (d. before A.D. 800) founded a monastery for Ṣūfīs at Ramleh in Palestine, but such fraternities seem to have been exceptional. Many ascetics of this period used to wander from place to place, either alone or in small parties, sometimes living by alms and sometimes by their own labour. They took up and emphasized certain Koranic terms. Thus *dhikr* (praise of God) consisting of recitation of the Koran, repetition of the Divine names, &c., was regarded as superior to the five canonical prayers incumbent on every Moslem, and *tawakkul* (trust in God) was defined as renunciation of all personal initiative and volition, leaving one's self entirely in God's hands, so that some fanatics deemed it a breach of "trust" to seek any means of livelihood, engage in trade, or even take medicine. Quietism soon passed into mysticism. The attainment of salvation ceased to be the first object, and every aspiration was centred in the inward life of dying to self and living in God. "O God!" said Ibrāhīm ibn Adham, "Thou knowest that the eight Paradises are little beside the honour which Thou hast done unto me, and beside Thy love, and Thy giving me intimacy with the praise of Thy name, and beside the peace of mind which Thou hast given me when I meditate on Thy majesty." Towards the end of the 2nd century we find the doctrine of mystical love set forth in the sayings of a female ascetic, Rābi'a of Basra, the first of a long line of saintly women who have played an important rôle in the history of Ṣūfiism. Henceforward the use of symbolical expressions, borrowed from the vocabulary of love and wine, becomes increasingly frequent as a means of indicating holy mysteries which must not be divulged. This was not an unnecessary precaution, for in the course of the 3rd century, Ṣūfiism assumed a new character. Side by side with the quietistic and devotional mysticism of the early period there now sprang up a speculative and pantheistic movement which was essentially anti-Islamic and rapidly came into conflict with the orthodox *ulemā*. It is significant that the oldest representative of this tendency—Ma'rūf of Bagdad—was the son of Christian parents and a Persian by race. He defined Ṣūfiism as a theosophy; his aim was "to apprehend the Divine realities." A little later Abū Sulaimān al-Dārānī in Syria and Dhu'l-Nūn in Egypt developed the doctrine of gnosis (ma'rifat) through illumination and ecstasy. The step to pantheism was first decisively taken by the great Persian Ṣūfī, Abū Yazīd (Bāyezīd) of Bisṭām (d. A.D. 874), who introduced the doctrine of annihilation (*fanā*), *i.e.* the passing away of individual consciousness in the will of God.

It is, no doubt, conceivable that the evolution of Ṣūfiism up to this point might not have been very different even although it had remained wholly unaffected by influences outside of Islam. But, as a matter of fact, such influences made themselves powerfully felt. Of these, Christianity, Buddhism and Neoplatonism are the chief. Christian influence had its source, not in the Church, but in the hermits and unorthodox sects, especially perhaps in the Syrian Euchites, who magnified the duty of constant prayer, abandoned their all and wandered as poor brethren. Ṣūfiism owed much to the ideal of unworldliness which they presented. Conversations between Moslem devotees and Christian ascetics are often related in the ancient Ṣūfī biographies, and many Biblical texts appear in the form of sayings attributed to eminent Ṣūfīs of early times, while sayings ascribed to Jesus as well as Christian and Jewish legends occur in abundance. More than one Ṣūfī doctrine—that of *tawakkul* may be mentioned in particular—show traces of Christian teaching. The monastic strain which insinuated itself into Ṣūfiism in spite of Mahomet's prohibition was derived, partially at any rate, from Christianity. Here, however, Buddhistic influence may also have been at work. Buddhism flourished in Balkh, Transoxiana and Turkestan before the Mahommedan conquest, and in later times Buddhist monks carried their religious practices and philosophy among the Moslems who had settled in these countries. It looks as though the legend of Ibrāhīm ibn Adham, a prince of Balkh who one day suddenly cast off his royal robes and became a wandering Ṣūfī, were based on the story of Buddha. The use of rosaries, the doctrine of *fanā*, which is probably a form of Nirvana, and the system of "stations" (*maqāmāt*) on the road thereto, would seem to be Buddhistic in their origin. The third great foreign influence on Ṣūfiism is the Neoplatonic philosophy. Between A.D. 800 and 860 the tide of Greek learning, then at its height, streamed into Islam from the Christian monasteries of Syria, from the Persian Academy of Jundēshāpūr in Khūzistan, and from the Ṣābians of Ḥarrān in Mesopotamia. The so-called "Theology of Aristotle," which was translated into Arabic about A. D. 840, is full of Neoplatonic theories, and the mystical writings of the pseudo-Dionysius were widely known throughout western Asia. It is not mere coincidence that the doctrine of Gnosis was first worked out in detail by the Egyptian Ṣūfī, Dhu 'l-Nūn (d. A.D. 859), who is described as an alchemist and theurgist. Ṣūfiism on its theosophical side was largely a product of Alexandrian speculation.

By the end of the 3rd century the main lines of the Ṣūfī mysticism were already fixed. It was now fast becoming an organized system, a school for saints, with rules of discipline and devotion which the novice was bound to learn from his spiritual director, to whose guidance he submitted himself absolutely. These directors regarded themselves as being in the most intimate communion with God, who bestowed on them miraculous gifts (*karāmāt*). At their head stood a mysterious personage called the *Quṭb* (Axis): on the hierarchy of saints over which he presided the whole order of the universe was believed to depend. During the next two hundred years (A.D. 900–1100), various manuals of theory and practice were compiled: the *Kitāb al Luma'* by Abū Naṣr al-Sarrāj, the *Qūt al-Qulūb* by Abū Ṭālib al-Makkī, the *Risāla* of Qushairī, the Persian *Kashf al-Maḥjūb* by 'Alī ibn 'Uthmān al-Hujwīrī, and the famous *Iḥyā* by Ghazālī. Inasmuch as all these works are founded on the same materials, viz., the Koran, the Traditions of the Prophet and the sayings of well-known Ṣūfī teachers, they necessarily have much in common, although the subject is treated by each writer from his own standpoint. They all expatiate on the discipline of the soul and describe the process of purgation which it must undergo before entering on the contemplative life. The traveller journeying towards God passes through a series of ascending "stations" (*maqāmāt*): in the oldest extant treatise these are (1) repentance, (2) abstinence, (3) renunciation, (4) poverty, (5) patience, (6) trust in God, (7) acquiescence in the will of God. After the "stations" comes a parallel scale of "states" of spiritual feeling (*aḥwāl*), such as fear, hope, love, &c., leading up to contemplation (*mushāhadat*) and intuition (*yaqīn*). It only remained to provide Ṣūfiism with a metaphysical basis, and to reconcile it with orthodox Islam. The double task was finally accomplished by Ghazālī (*q.v.*). He made Islamic theology mystical, and since his time the revelation (*kashf*) of the mystic has taken its place beside tradition (*naql*) and reason (*'aql*) as a source and fundamental principle of the faith. Protests have been and are still raised by theologians, but Moslem sentiment will usually tolerate whatever is written in sufficiently abstruse philosophical language or spoken in manifest ecstasy.

The Ṣūfīs do not form a sect with definite dogmas. Like the monastic orders of Christendom, they comprise many shades of opinion, many schools of thought, many divergent tendencies—from asceticism and quietism to the wildest extravagances of pantheism. European students of Ṣūfiism are apt to identify it with the pantheistic type which prevails in Persia. This, although more interesting and attractive than any other, throws the transcendental and visionary aspects of Ṣūfiism into undue relief. Nevertheless some account must be given here of the Persian theosophy which has fascinated the noblest minds of that subtle race and has inspired the most beautiful religious poetry in the world. Some of its characteristic features occur in the sayings attributed to Bāyezīd (d. A.D. 874), whom Buddhistic ideas unquestionably influenced. He said, for example, "I am the winedrinker and the wine and the cup-bearer," and again, "I went from God to God, until they cried from me in me, 'O Thou I.'" The peculiar imagery which distinguishes the poetry of the Persian Ṣūfīs was more fully developed by a native of Khorasan, Abū Sa'īd ibn Abi'l-Khair (d. A.D. 1049) in his mystical quatrains which express the relation between God and the soul by glowing and fantastic allegories of earthly love, beauty and intoxication. Henceforward, the great poets of Persia, with few exceptions, adopt this symbolic language either seriously or as a convenient mask. The majority are Ṣūfīs by profession or conviction. "The real basis of their poetry," says A. von Kremer, "is a loftily inculcated ethical system, which recognizes in purity of heart, charity, self-renunciation and bridling of the passions the necessary conditions of eternal happiness. Attached to this we find a pantheistic theory of the emanation of all things from God and their ultimate reunion with him. Although on the surface Islam is not directly assailed, it sustains many indirect attacks, and frequently the thought flashes out, that all religions and revelations are only the rays of a single eternal sun; that all prophets have only delivered and proclaimed in different tongues the same principles of eternal goodness and eternal truth which flow from the divine soul of the world." The whole doctrine of Persian Ṣūfiism is expounded in the celebrated *Mathnawī* of Jalāluddīn Rūmī (*q.v.*), but in such a discursive and unscientific manner that its leading principles are not easily grasped. They may be stated briefly as follows:—

God is the sole reality (al-Ḥaqq) and is above all names and definitions. He is not only absolute Being, but also absolute Good, and therefore absolute Beauty. It is the nature of beauty to desire manifestation; the phenomenal universe is the result of this desire, according to the famous Tradition in which God says, "I was a hidden treasure, and I desired to be known, so I created the creatures in order that I might be known." Hence the Ṣūfīs, influenced by Neoplatonic theories of emanation, postulate a number of intermediate worlds or descending planes of existence, from the primal Intelligence and the primal Soul, through which "the Truth" (*al-Ḥaqq*) diffuses itself. As things can be known only through their opposites, Being can only be known through Not-being, wherein as in a mirror Being is reflected; and this reflection is the phenomenal universe, which accordingly has no more reality than a shadow cast by the sun. Its central point is Man, the microcosm, who reflects in himself all the Divine attributes. Blackened on one side with the darkness of Not-being, he bears within him a spark of pure Being. The human soul belongs to the spiritual world and is ever seeking to be re-united to its source. Such union is hindered by the bodily senses, but though not permanently attainable until death, it can be enjoyed at times in the state called ecstasy (*ḥāl*), when the veil of sensual perception is rent asunder and the soul is merged in God. This cannot be achieved without destroying the illusion of self, and self-annihilation is wrought by means of that divine love, to which human love is merely a stepping-stone. The true lover feels himself one with God, the only real being and agent in the universe; he is above all law, since whatever he does proceeds directly from God, just as a flute produces harmonies or discords at the will of the musician; he is indifferent to outward forms and rites, preferring a sincere idolater to an orthodox hypocrite and deeming the ways to God as many in number as the souls of men. Such in outline is the Ṣūfī theosophy as it appears in Persian and Turkish poetry. Its perilous consequences are plain. It tends to abolish the distinction between good and evil—the latter is nothing but an aspect of Not-being and has no real existence—and it leads to the deification of the hierophant who can say, like Ḥusain b. Manṣur al-Ḥallāj, "I am the Truth." Ṣūfī fraternities, living in a convent under the direction of a sheikh, became widely spread before A.D. 1100 and gave rise to Dervish orders, most of which indulge in the practice of exciting ecstasy by music, dancing, drugs and various kinds of hypnotic suggestion (see DERVISH).

SUGAR, in chemistry, the generic name for a certain series of carbohydrates, *i.e.* substances of the general formula $C_n(H_2O)_m$. Formerly the name was given to compounds having a sweet taste, *e.g.* sugar of lead, but it is now restricted to certain oxy-aldehydes and oxy-ketones, which occur in the vegetable and animal kingdoms either free or in combination as glucosides (*q.v.*) and to artificial preparations of similar chemical structure. Cane sugar has been known for many centuries; milk sugar was obtained by Fabrizio Bartoletti in 1615; and in the middle of the 18th century Marggraf found that the sugars yielded by the beet, carrot and other roots were identical with cane sugar. The sugars obtained from honey were investigated by Lowitz and Proust, and the latter decided on three species: (1) cane sugar, (2) grape sugar, and (3) fruit sugar; the first has the formula $C_{12}H_{22}O_{11}$, the others $C_6H_{12}O_6$. This list has been considerably developed by the discovery of natural as well as of synthetic sugars.

It is convenient to divide the sugars into two main groups: monosaccharoses (formerly glucoses) and disaccharoses (formerly saccharoses). The first term includes simple sugars containing two to nine atoms of carbon, which are known severally as bioses, trioses, tetroses, pentoses, hexoses, &c.; whilst those of the second group have the formula $C_{12}H_{22}O_{11}$ and are characterized by yielding two monosaccharose molecules on hydrolysis. In addition trisaccharoses are known of the formula $C_{18}H_{32}O_{16}$; these on hydrolysis yield one molecule of a monosaccharose and one of a disaccharose, or three of a monosaccharose. It is found also that some monosaccharoses behave as aldehydes whilst others contain a keto group; those having the first character are called *aldoses*, and the others *ketoses*. All sugars are colourless solids or syrups, which char on strong heating; they are soluble in water, forming sweet solutions but difficultly soluble in alcohol. Their solutions are optically active, *i.e.* they rotate the plane of polarized light; the amount of the rotation being dependent upon the concentration, temperature, and, in some cases, on the age of the solution (cf. GLUCOSE). The rotation serves for the estimation of sugar solutions (saccharimetry). They are neutral to litmus and do not combine with dilute acids or bases; strong bases, such as lime and baryta, yield saccharates, whilst, under certain conditions, acids and acid anhydrides may yield esters. Sugars are also liable to fermentation.[1] Our knowledge of the chemical structure of the monosaccharoses may be regarded as dating from 1880, when Zincke suspected some to be ketone alcohols, for it was known that glucose and fructose, for example, yielded penta-acetates, and on reduction gave hexahydric alcohols, which, when reduced by hydriodic acid, gave normal and secondary hexyliodide. The facts suggested that the six carbon atoms formed a chain, and that a hydroxy group was attached to five of them, for it is very rare for two hydroxy groups to be attached to the same carbon atom. The remaining oxygen atom is aldehydic or ketonic, for the sugars combine with hydrocyanic acid, hydroxylamine and phenylhydrazine. The correctness of this view was settled by Kiliani in 1885. He prepared the cyanhydrins of glucose and fructose, hydrolysed them to the corresponding oxy-acids, from which the hydroxy groups were split out by reduction; it was found that glucose yielded normal heptylic acid and fructose methylbutylacetic acid; hence glucose is an aldehyde alcohol, $CH_2OH\cdot(CH\cdot OH)_4\cdot CHO$, whilst fructose is a ketone alcohol $CH_2OH\cdot(CH\cdot OH)_3\cdot CO\cdot CH_2OH$.[2] Kiliani also showed that arabinose, $C_5H_{10}O_5$, a sugar found in cherry gum, was an aldopentose, and thus indicated an extension of the idea of a "sugar."

Before proceeding to the actual synthesis of the sugars, it is advisable to discuss their decompositions and transformations.

1. *Cyanhydrins.*—The cyanhydrins on hydrolysis give monocarboxylic acids, which yield lactones; these compounds when reduced by sodium amalgam in sulphuric acid solution yield a sugar containing one more carbon atom. This permits the formation of a higher from a lower sugar (E. Fischer)

$$\begin{array}{lclclcl}
CH_2OH & & CH_2OH & & CH_2OH & & CH_2OH \\
\dot{C}H\cdot OH & & \dot{C}H\cdot OH & & \dot{C}H & & \dot{C}H\cdot OH \\
(\dot{C}H\cdot OH)_2 & \rightarrow & (\dot{C}H\cdot OH)_2 & \rightarrow O & (\dot{C}H\cdot OH)_2 & \rightarrow & (\dot{C}H\cdot OH)_2 \\
\dot{C}HO & & \dot{C}H\cdot OH & & \dot{C}H\cdot OH & & \dot{C}H\cdot OH \\
 & & \dot{C}N & & \dot{C}O & & \dot{C}HO \\
\text{Pentose} & \rightarrow & \text{Cyanhydrin} & \rightarrow & \text{Lactone} & \rightarrow & \text{Hexose.}
\end{array}$$

2. *Oximes.*—The oximes permit the reverse change, *i.e.* the passage from a higher to a lower sugar. Wohl forms the oxime and converts it into an acetylated nitrile by means of acetic anhydride and sodium acetate; ammoniacal silver nitrate solution removes hydrocyanic acid and the resulting acetate is hydrolysed by acting with ammonia to form an amide, which is finally decomposed with sulphuric acid.

$$\begin{array}{lclclcl}
CH_2OH & & CH_2OH & & CH_2OH & & CH_2OH \\
(\dot{C}H\cdot OH)_3 & \rightarrow & (\dot{C}H\cdot OH)_3 & \rightarrow & (\dot{C}H\cdot OH)_2 & \rightarrow & (\dot{C}H\cdot OH)_3 \\
\dot{C}H\cdot OH & & \dot{C}H\cdot OH & & \dot{C}H\cdot OH & & \dot{C}HO \\
\dot{C}HO & & \dot{C}H{:}NOH & & \dot{C}N & & \\
\text{Hexose} & \rightarrow & \text{Oxime} & \rightarrow & \text{Nitrile} & \rightarrow & \text{Pentose.}
\end{array}$$

Ruff effects the same change by oxidizing the sugar to the oxy-acid, and then further oxidizing this with Fenton's reagent, *i.e.* hydrogen peroxide and a trace of a ferrous salt:

$$\begin{array}{ccccc}
C_4H_9O_4(CH\cdot OH)\cdot CHO & \rightarrow & C_4H_9O_4(CH\cdot OH)\cdot CO_2H & \rightarrow & C_4H_9O_4\cdot CHO \\
\text{Hexose} & \rightarrow & \text{Acid} & \rightarrow & \text{Pentose.}
\end{array}$$

3. *Phenylhydrazine Derivatives.*—Fischer found that if one molecule of phenylhydrazine acted upon one molecule of an aldose or ketose a hydrazone resulted which in most cases was very soluble in water, but if three molecules of the hydrazine reacted (one of which is reduced to ammonia and aniline) insoluble crystalline substances resulted, termed *osazones*, which readily characterized the sugar from which it was obtained.

$$\begin{array}{lclcl}
R & & R & & R \\
\dot{C}H\cdot OH & \rightarrow & \dot{C}H\cdot OH & \rightarrow & \dot{C}{:}N\cdot NHPh \\
\dot{C}HO & & \dot{C}H{:}N\cdot NHPh. & & \dot{C}H{:}N\cdot NHPh. \\
\text{Aldose} & \rightarrow & \text{Hydrazone} & \rightarrow & \text{Osazone;} \\
R & & R & & R \\
\dot{C}O & \rightarrow & \dot{C}{:}N\cdot NHPh. & \rightarrow & \dot{C}{:}N\cdot NHPh \\
\dot{C}H_2OH & & \dot{C}H_2OH & & \dot{C}H{:}N\cdot NHPh. \\
\text{Ketose} & \rightarrow & \text{Hydrazone} & \rightarrow & \text{Osazone.}
\end{array}$$

On warming the osazone with hydrochloric acid the phenylhydrazine residues are removed and an *osone* results, which on reduction with zinc and acetic acid gives a ketose.

$$\begin{array}{lclcl}
R & & R & & R \\
\dot{C}{:}N\cdot NHPh. & \rightarrow & \dot{C}O & \rightarrow & \dot{C}O \\
\dot{C}H{:}N\cdot NHPh. & & \dot{C}HO & & \dot{C}H_2OH \\
\text{Osazone} & \rightarrow & \text{Osone} & \rightarrow & \text{Ketose.}
\end{array}$$

A ketose may also be obtained by reducing the osazone with zinc and acetic to an *osamine*, which with nitrous acid gives the ketose:

$$\begin{array}{lclcl}
R & & R & & R \\
\dot{C}{:}N\cdot NHPh. & \rightarrow & \dot{C}O & \rightarrow & \dot{C}O \\
\dot{C}H{:}N\cdot NHPh. & & \dot{C}H_2NH_2 & & \dot{C}H_2OH. \\
\text{Osazone} & \rightarrow & \text{Osamine} & \rightarrow & \text{Ketose.}
\end{array}$$

These reactions permit the transformation of an aldose into a ketose; the reverse change can only be brought about by reducing the ketose to an alcohol, and oxidizing this compound to an aldehyde. It is seen that aldoses and ketoses which differ stereochemically in only the two final carbon atoms must yield the same osazone; and since *d*-mannose, *d*-glucose, and *d*-fructose do form the same osazone (*d*-glucosazone) differences either structural or stereochemical must be placed in the two final carbon atoms.[3]

It may here be noticed that in the sugars there are asymmetric carbon atoms, and consequently optical isomers are to be expected. Thus glucose, containing four such atoms, can exist in 16 forms; and the realization of many of these isomers by E. Fischer may be regarded as one of the most brilliant achievements in modern chemistry. The general principles of stereochemistry being discussed in Stereoisomerism (*q.v.*), we proceed to the synthesis of glucose and fructose and then to the derivation of their configurations.

In 1861 Butlerow obtained a sugar-like substance, methylenitan, by digesting trioxymethylene, the solid polymer of formaldehyde, with lime. The work was repeated by O. Loew, who prepared in 1885 a sweet, unfermentable syrup, which he named formose, $C_6H_{12}O_6$ and, later, by using magnesia instead of lime, he obtained the fermentable methose. Fischer showed that methose was identical with the α-acrose obtained by himself and Tafel in 1887 by decomposing acrolein dibromide with baryta, and subsequently prepared by oxidizing glycerin with bromine in alkaline solution, and treating the product with dilute alkali at 0°. Glycerin appears to yield, on mild oxidation, an aldehyde, $CH_2OH\cdot CH(OH)\cdot CHO$, and a ketone, $CH_2OH\cdot CO\cdot CH_2OH$, and these condense as shown in the equation:

$$CH_2OH\cdot CH(OH)\cdot CHO + CH_2OH\cdot CO\cdot CH_2OH = CH_2OH\cdot CH(OH)\cdot CH(OH)\cdot CH(OH)\cdot CO.CH_2OH + H_2O.$$

The osazone prepared from α-acrose resembled most closely the glucosazone yielded by glucose, mannose, and fructose, but it was optically inactive; also the ketose which it gave after treatment with hydrochloric acid and reduction of the osone was like ordinary fructose except that it was inactive. It was surmised that α-acrose was a mixture of dextro and laevo fructose, a supposition which was proved correct by an indirect method. The starting point was ordinary (*d*) mannite (mannitol), $C_6H_{14}O_6$, a naturally occurring hexahydric alcohol, which only differed from α-acritol, the alcohol obtained by reducing α-acrose, with regard to optical activity. Mannite on oxidation yields an aldose, mannose, $C_6H_{12}O_6$, which

[1] See FERMENTATION; and for the relation of this property to structure see STEREOISOMERISM.

[2] These formulae, however, require modification in accordance with the views of Lowry and E. F. Armstrong, which postulate a γ oxidic structure (see GLUCOSE). This, however, does not disturb the tenor of the following arguments.

[3] To distinguish the isomerides of opposite optical activity, it is usual to prefix the letters *d-* and *l-*, but these are used only to indicate the genetic relationship, and not the character of the optical activity; ordinary fructose, for example, being represented as *d*-fructose—although it exercises a laevorotatory power—because it is derived from *d*-glucose.

on further oxidation gives a mannonic acid, $C_5H_6(OH)_5\cdot CO_2H$; this acid readily yields a lactone. Also Kiliani found that the lactone derived from the cyanhydrin of natural arabinose (laevo) was identical with the previous lactone except that its rotation was equal and opposite. On mixing the eslactones and reducing $(d+l)$-mnanitol was obtained, identical with α-acritol. A separation of α-acrose was made by acting with beer yeast, which destroyed the ordinary fructose and left *l*-fructose which was isolated as its osazone. Also $(d+l)$ mannonic acid can be split into the *d* and *l* acids by fractional crystallization of the strychnine or brucine salts. The acid yields, on appropriate treatment, *d*-mannose and *d*-mannite. Similarly the *l* acid yields the laevo derivatives.

The next step was to prepare glucose. This was effected indirectly. The identity of the formulae and osazones of *d*-mannose and *d*-glucose showed that the stereochemical differences were situated at the carbon atom adjacent to the aldehyde group. Fischer applied a method indicated by Pasteur in converting dextro into laevo-tartaric acid; he found that both *d*-mannonic and *d*-gluconic acids (the latter is yielded by glucose on oxidation) were mutually convertible by heating with quinoline under pressure at 140°. It was then found that on reducing the lactone of the acid obtained from *d*-mannonic acid, ordinary glucose resulted.

Fischer's α-acrose therefore led to the synthesis of the dextro and laevo forms of mannose, glucose and fructose; and these substances have been connected synthetically with many other sugars by means of his cyanhydrin process, leading to higher sugars, and Wohl and Ruff's processes, leading to lower sugars. Certain of these relations are here summarized (the starting substance is in italics):—

l-Glucose ⟵ l-*arabinose* ⟶ *l*-mannose ⟶ *l*-mannoheptose;
glucononose ⟵ α-gluco-octose ⟵ α-glucoheptose ⟵ d-*glucose* ⟶ β-glucoheptose ⟶ β-gluco-octose;
d-*mannose*⟶*d*-mannoheptose⟶manno-octose⟶mannononose;
d-*glucose* ⟶ *d*-arabinose ⟶ *d*-erythrose.
l-*glucose*⟶ *b*-arabinose ⟶ *l*-erythrose.

Their number is further increased by spatial inversion of the dicarboxylic acids formed on oxidation, followed by reduction; for example: *d*- and *l*-glucose yield *d*-and *l*-gulose; and also by Lobry de Bruyn and Van Ekenstein's discovery that hexoses are transformed into mixtures of their isomers when treated with alkalis, alkaline earths, lead oxide, &c.

Monosaccharoses.

Biose.—The only possible biose is glycollic aldehyde, $CHO\cdot CH_2OH$, obtained impure by Fischer from bromacetaldehyde and baryta water, and crystalline by Fenton by heating dihydroxymaleic acid with water to 60°. It polymerizes to a tetrose under the action of sodium hydroxide.

Trioses.—The trioses are the aldehyde and ketone mentioned above as oxidation products of glycerin. Glyceric aldehyde, $CH_2OH\cdot CH(OH)\cdot CHO$, was obtained pure by Wohlon oxidizing acrolein acetal, $CH_2\cdot CH(OC_2H_5)_2$, and hydrolysing. Although containing an asymmetric carbon atom it has not been resolved. The ketone, dihydroxyacetone, $CH_2OH\cdot CO\cdot CH_2OH$, was obtained by Piloty by condensing formaldehyde with nitromethane, reducing to a hydroxylamino compound, which is oxidized to the oxime of dihydroxyacetone; the ketone is liberated by oxidation with bromine water:

$$3H\cdot CHO + CH_3NO_2 \rightarrow (CH_2OH)_3C\cdot NO_2 \rightarrow (CH_2OH)_3C\cdot NH\ OH \rightarrow (CH_2OH)_2C:NOH \rightarrow (CH_2OH)_2CO.$$

The ketone is also obtained when Bertrand's *sorbose bacterium* acts on glycerol; this medium also acts on other alcohols to yield ketoses; for example: erythrite gives erythrulose, arabite arabinulose, mannitol fructose, &c.

Tetroses.—Four active tetroses are possible, and three have been obtained by Ruff and Wohl from the pentoses. Thus Wohl prepared *l*-threose from *l*-xylose and *l*-erythrose from *l*-arabinose, and Ruff obtained *d*- and *l*-erythrose from *d*- and *l*-arabonic acids, the oxidation products of *d*- and *l*-arabinoses. Impure inactive forms result on the polymerization of glycollic aldehyde and also on the oxidation of erythrite, a tetrahydric alcohol found in some lichens. *d*-Erythrulose is a ketose of this series.

Pentoses.—Eight stereoisomeric pentaldoses are possible, and six are known: *d*- and *l*-arabinose, *d*- and *l*-xylose, *l*-ribose, and *d*-lyxose. Scheibler discovered *l*-arabinose in 1869, and regarded it as a glucose; in 1887 Kiliani proved it to be a pentose. *d*-Arabinose is obtained from *d*-glucose by Wohl's method. *l*-Xylose was discovered by Koch in 1886; its enantiomorph is prepared from *d*-gulose by Wohl's method. *l*-Ribose and *d*-lyxose are prepared by inversion from *l*-arabinose and *l*-xylose; the latter has also been obtained from *d*-galactose. We may notice that the pentoses differ from other sugars by yielding furfurol when boiled with hydrochloric acid. Rhamnose or isodulcite, a component of certain glucosides, fucose, found combined in seaweeds and chinovose, present as its ethyl ester, chinovite, in varieties of quina-bark, are methyl pentoses. *l*-Arabinulose obtained from arabite and Bertrand's *sorbium bacterium* is a ketose.

Hexoses.—The hexoses may be regarded as the most important sub-division of the monosaccharoses. The reader is referred to Glucose and Fructose for an account of these substances. The next important aldose is mannose. *d*-Mannose, first prepared by oxidizing *d*-mannite, found in plants and manna-ash (*Fraxinus ornus*), was obtained by Tollens and Gans on hydrolysing cellulose and by Reis from seminine (reserve cellulose), found in certain plant seeds, *e.g.* vegetable ivory. *l*-Mannose is obtained from *l*-mannonic acid. Other forms are: *d*- and *l*-gulose, prepared from the lactones of the corresponding gulonic acids, which are obtained from *d*- and *l*-glucose by oxidation and inversion; *d*- and *l*-idose, obtained by inverting with pyridine *d*- and *l*-gulonic acids, and reducing the resulting idionic acids; *d*- and *l*-galactose, the first being obtained by hydrolysing milk sugar with dilute sulphuric acid, and the second by fermenting inactive galactose (from the reduction of the lactone of *d*, *l*-galactonic acid) with yeast; and *d*- and *l*-talose obtained by inverting the galactonic acids by pyridine into *d*- and *l*-talonic acids and reduction. Of the ketoses, we notice *d*-sorbose, found in the berries of mountain-ash, and *d*-tagatose, obtained by Lobry de Bruyn and van Ekenstein on treating galactose with dilute alkalis, talose and *l*-sorbose being formed at the same time. The higher sugars call for no special notice.

Configuration of the Hexaldoses.[1]—The plane projection of molecular structures which differ stereochemically is discussed under Stereoisomerism; in this place it suffices to say that, since the terminal groups of the hexaldose molecule are different and four asymmetric carbon atoms are present, sixteen hexaldoses are possible; and for the hexahydric alcohols which they yield on reduction, and the tetrahydric dicarboxylic acids which they give on oxidation, only ten forms are possible. Employing the notation in which the molecule is represented vertically with the aldehyde group at the bottom, and calling a carbon atom + or − according as the hydrogen atom is to the left or right, the possible configurations are shown in the diagram. The grouping of the forms 5 to 10 with 11 to 16 is designed to show that the pairs 5, 11 for example become identical when the terminal groups are the same.

				11	12	13	14	15	16
				+	+	+	+	+	−
				+	+	+	−	−	+
				+	−	−	+	−	−
				−	+	−	−	−	−
+	+	−	−	−	+	−	−	−	−
+	−	+	−	+	−	−	+	−	−
+	−	+	−	+	+	+	−	−	+
+	+	−	−	+	+	+	+	+	−
1	2	3	4	5	6	7	8	9	10

We can now proceed to the derivation of the structure of glucose. Since both *d*-glucose and *d*-gulose yield the same active (*d*) saccharic acid on oxidation, the configuration of this and the corresponding *l*-acid must be sought from among those numbered 5–10 in the above table. Nos. 7 and 8 can be at once ruled out, however, as acids so constituted would be optically inactive and the saccharic acids are active. If the configuration of *d*-saccharic acid were given by either 6 or 10, bearing in mind the relation of mannose to glucose, it would then be necessary to represent *d*-mannosaccharic acid by either 7 or 8—as the forms 6 and 10 pass into 7 and 8 on changing the sign of a terminal group; but this cannot be done as mannosaccharic acid is optically active. Nos. 6 and 10 must, in consequence, also be ruled out. No. 5, therefore, represents the configuration of one of the saccharic acids, and No. 9 that of the isomeride of equal opposite rotatory power. As there is no means of distinguishing between the configuration of a dextro- and laevo-modification, an arbitrary assumption must be made. No. 5 may therefore be assigned to the *d*- and No. 9 to the *l*-acid. It then follows that *d*-mannose is represented by No. 1, and *l*-mannose by No. 4, as mannose is produced by reversing the sign of the asymmetric system adjoining the terminal COH group.

It remains to distinguish between 5 and 11, 9 and 15 as representing glucose and gulose. To settle this point it is necessary to consider the configuration of the isomeric pentoses—arabinose and xylose—from which they may be prepared. Arabinose being convertible into *l*-glucose and xylose into *l*-gulose, the alternative formulae to be considered are—

$$CH_2(OH)---+COH$$
$$CH_2(OH)+++-COH.$$

[1] The following account is mainly from H. E. Armstrong's article Chemistry in the 10th edition of this Encyclopaedia; the representation differs from the projection of Meyer and Jacobsen.

If the asymmetric system adjoining the COH group, which is that introduced in synthesizing the hexose from the pentose, be eliminated, the formulae at disposal for the two pentoses are

$$CH_2(OH)---COH$$
$$CH_2(OH)+--COH.$$

When such compounds are converted into corresponding dibasic acids, $CO_2H.[CH(OH)]_3.CO_2H$, the number of asymmetric carbon atoms becomes reduced from three to two, as the central carbon atom is then no longer associated with four, but with only three different radicles. Hence it follows that the "optical" formulae of the acids derived from two pentoses having the configuration given above will be

$$CO_2H-0-CO_2H$$
$$CO_2H+0-CO_2H,$$

and that consequently only one of the acids will be optically active. As a matter of fact, only arabinose gives an active product on oxidation; it is therefore to be supposed that arabinose is the $---$ compound, and consequently

$$CH_2(OH)---+COH = l\text{-glucose}$$
$$CH_2(OH)+---COH = l\text{-gulose}.$$

When xylose is combined with hydrocyanic acid and the cyanide is hydrolysed, together with *l*-gulonic acid, a second isomeric acid, *l*-idonic acid, is produced, which on reduction yields the hexaldose *l*-idose. When *l*-gulonic acid is heated with pyridine, it is converted into *l*-idonic acid, and vice versa; and *d*-gulonic acid may in a similar manner be converted into *d*-idonic acid, from which it is possible to prepare *d*-idose. It follows from the manner in which *l*-idose is produced that its configuration is $CH_2(OH)+---+COH$.

The remaining aldohexoses discovered by Fischer are derived from *d*-galactose from milk-sugar. When oxidized this aldohexose is first converted into the monobasic galactonic acid, and then into dibasic mucic acid; the latter is optically inactive, so that its configuration must be one of those given in the sixth and seventh columns of the table. On reduction it yields an inactive mixture of galactonic acids, some molecules being attacked at one end, as it were, and an equal number of others at the other. On reducing the lactone prepared from the inactive acid an inactive galactose is obtained from which *l*-galactose may be separated by fermentation. Lastly, when *d*-galactonic acid is heated with pyridine, it is converted into talonic acid, which is reducible to talose, an isomeride bearing to galactose the same relation that mannose bears to glucose. It can be shown that *d*-galactose is $CH_2(OH)+-+-COH$, and hence *d*-talose is $CH_2(OH)+-++COH$.

The configurations of the penta-and tetra-aldoses have been determined by similar arguments; and those of the ketoses can be deduced from the aldoses.

Disaccharoses.

The disaccharoses have the formula $C_{12}H_{22}O_{11}$ and are characterized by yielding under suitable conditions two molecules of a hexose: $C_{12}H_{22}O_{11}+H_2O=C_6H_{12}O_6+C_6H_{12}O_6$. The hexoses so obtained are not necessarily identical: thus cane sugar yields *d*-glucose and *d*-fructose (invert sugar); milk sugar and melibiose give *d*-glucose and *d*-galactose, whilst maltose yields only glucose. Chemically they appear to be ether anhydrides of the hexoses, the union being effected by the aldehyde or alcohol groups, and in consequence they are related to the ethers of glucose and other hexoses, *i.e.* to the alkyl glucosides. Cane sugar has no reducing power and does not form an hydrazone or osazone; the other varieties, however, reduce Fehling's solution and form hydrazones and osazones, behaving as aldoses, *i.e.* as containing the group $\cdot CH(OH)\cdot CHO$. The relation of the disaccharoses to the α- and β-glucosides was established by E. F. Armstrong (*Journ. Chem. Soc.*, 1903, 85, 1305), who showed that cane sugar and maltose were α-glucosides, and raffinose an α-glucoside of melibiose. These and other considerations have led to the proposal of an alkylen oxide formula for glucose, first proposed by Tollens; this view, which has been mainly developed by Armstrong and Fischer, has attained general acceptance (see Glucose and Glucoside). Fischer has proposed formulae for the important disaccharoses, and in conjunction with Armstrong devised a method for determining how the molecule was built up, by forming the osone of the sugar and hydrolysing, whereupon the hexosone obtained indicates the aldose part of the molecule. Lactose is thus found to be glucosido-galactose and melibiose a galactosido-glucose.

Several disaccharoses have been synthesized. By acting with hydrochloric acid on glucose Fischer obtained isomaltose, a disaccharose very similar to maltose but differing in being amorphous and unfermentable by yeast. Also Marchlewski (in 1899) synthesized cane sugar from potassium fructosate and acetochloroglucose; and after Fischer discovered that acetochlorohexoses readily resulted from the interaction of the hexose penta-acetates and liquid hydrogen chloride, several others have been obtained.

Cane sugar, saccharose or saccharobiose, is the most important sugar; its manufacture is treated below. When slowly crystallized it forms large monoclinic prisms which are readily soluble in water but difficultly soluble in alcohol. It melts at 160°, and on cooling solidifies to a glassy mass, which on standing gradually becomes opaque and crystalline. When heated to about 200° it yields a brown amorphous substance, named caramel, used in colouring liquors, &c. Concentrated sulphuric acid gives a black carbonaceous mass; boiling nitric acid oxidizes it to *d*-saccharic, tartaric and oxalic acids; and when heated to 160° with acetic anhydride an octa-acetyl ester is produced. Like glucose it gives saccharates with lime, baryta and strontia.

Milk sugar, lactose, lactobiose, $C_{12}H_{22}O_{11}$, found in the milk of mammals, in the amniotic liquid of cows, and as a pathological secretion, is prepared by evaporating whey and purifying the sugar which separates by crystallization. It forms hard white rhombic prisms (with $1H_2O$), which become anhydrous at 140° and melt with decomposition at 205°. It reduces ammoniacal silver solutions in the cold, and alkaline copper solutions on boiling. Its aqueous solution has a faint sweet taste, and is dextro-rotatory, the rotation of a fresh solution being about twice that of an old one. It is difficultly fermented by yeast, but readily by the lactic acid bacillus. It is oxidized by nitric acid to *d*-saccharic and mucic acids; and acetic anhydride gives an octa-acetate.

Maltose, malt-sugar, maltobiose, $C_{12}H_{22}O_{11}$, is formed, together with dextrine, by the action of malt diastase on starch, and as an intermediate product in the decomposition of starch by sulphuric acid, and of glycogen by ferments. It forms hard crystalline crusts (with $1H_2O$) made up of hard white needles.

Less important disaccharoses are: Trehalose or mycose, $C_{12}H_{22}O_{11}\cdot 2H_2O$, found in various fungi, *e.g. Boletus edulis*, in the Oriental *Trehala* and in ergot of rye; melibiose, $C_{12}H_{22}O_{11}$, formed, with fructose, on hydrolysing the trisaccharose melitose (or raffinose), $C_{18}H_{32}O_{16}\cdot 5H_2O$, which occurs in Australian manna and in the molasses of sugar manufacture; touranose, $C_{12}H_{22}O_{11}$, formed with *d*-glucose and galactose on hydrolysing another trisaccharose, melizitose, $C_{18}H_{32}O_{16}\cdot 2H_2O$, which occurs in *Pinus larix* and in Persian manna; and agavose, $C_{12}H_{22}O_{11}$, found in the stalks of *Agave americana*. (X.)

Sugar Manufacture

Sugar-cane is a member of the grass family, known botanically as *Saccharum officinarum*, the succulent stems of which are the source of cane sugar. It is a tall perennial grass-like plant, giving off numerous erect stems 6 to 12 ft. or more in height from a thick solid jointed root-stock. The stems are solid and marked with numerous shining, polished, yellow, purple or striped joints, 3 in. or less in length, and about 1½ in. thick. They are unbranched and bear in the upper portion numerous long narrow grass-like leaves arranged in two rows; the leaf springs from a large sheath and has a more or less spreading blade 3 ft. in length or longer, and 3 in. or more wide. The small flowers or spikelets are borne in pairs on the ultimate branches of a much branched feathery plume-like terminal grey inflorescence, 2 ft. or more long. Production of flowers is uncertain under cultivation and seed is formed very rarely. The plant is readily propagated by cuttings, a piece of the stem bearing buds at its nodes will root rapidly when placed in sufficiently moist ground. The sugar-cane is widely cultivated in the tropics and some sub-tropical countries, but is not known as a wild plant. Its native country is unknown, but it probably originated in India or some parts of eastern tropical Asia where it has been cultivated from great antiquity and whence its cultivation spread westwards and eastwards. Alphonse de Candolle (*Origin of Cultivated Plants*, p. 158) points out that the epoch of its introduction into different countries agrees with the idea that its origin was in India, Cochin-China or the Malay Archipelago, and regards it as most probable that its primitive range extended from Bengal to Cochin-China. The sugar-cane was introduced by the Arabs in the middle ages into Egypt, Sicily and the south of Spain where it flourished until the abundance of sugar in the colonies caused its cultivation to be abandoned. Dom Enrique, Infante of Portugal, surnamed the Navigator (1394–1460) transported it about 1420, from Cyprus and Sicily to Madeira, whence it was taken to the Canaries in 1503, and thence to Brazil and Hayti early in the 16th century, whence it spread to Mexico, Cuba, Guadeloupe and Martinique, and later to Bourbon. It was introduced into Barbadoes from Brazil in 1641, and was distributed from there to other West Indian islands. Though cultivated in sub-tropical countries such as Natal and the Southern states of the Union, it is essentially tropical in its requirements and succeeds best in warm damp climates such as

Cuba, British Guiana and Hawaii, and in India and Java in the Old World. The numerous cultivated varieties are distinguished mainly by the colour of the internodes, whether yellow, red or purple, or striped, and by the height of the culm. Apart from the sugar-cane and the beet, which are dealt with in detail below, a brief reference need only be made here to maple sugar, palm sugar and sorghum sugar.

Maple Sugar.—This is derived from the sap of the rock or sugar maple (*Acer saccharinum*), a large tree growing in Canada and the United States.

The sap is collected in spring, just before the foliage develops, and is procured by making a notch or boring a hole in the stem of the tree about 3 ft. from the ground. A tree may yield 3 gallons of juice a day and continue flowing for six weeks; but on an average only about 4 ℔ of sugar are obtained from each tree, 4 to 6 gallons of sap giving 1 ℔ of sugar. The sap is purified and concentrated in a simple manner, the whole work being carried on by farmers, who themselves use much of the product for domestic and culinary purposes.

Palm Sugar.—That which comes into the European market as *jaggery* or *khaur* is obtained from the sap of several palms, the wild date (*Phoenix sylvestris*), the palmyra (*Borassus flabellifer*), the coco-nut (*Cocos nucifera*), the gomuti (*Arenga saccharifera*) and others. The principal source is *Phoenix sylvestris*, which is cultivated in a portion of the Ganges valley to the north of Calcutta. The trees are ready to yield sap when five years old; at eight years they are mature, and continue to give an annual supply till they reach thirty years. The collection of the sap (toddy) begins about the end of October and continues, during the cool season, till the middle of February. The sap is drawn off from the upper growing portion of the stem, and altogether an average tree will run in a season 350 ℔ of toddy, from which about 35 ℔ of raw sugar—jaggery—is made by simple and rude processes. Jaggery production is entirely in native hands, and the greater part of the amount made is consumed locally; it only occasionally reaches the European market.

Sorghum Sugar.—The stem of the Guinea corn or sorghum (*Sorghum saccharatum*) has long been known in China as a source of sugar. The sorghum is hardier than the sugar-cane; it comes to maturity in a season; and it retains its maximum sugar content a considerable time, giving opportunity for leisurely harvesting. The sugar is obtained by the same method as cane sugar.

Cane Sugar Manufacture.—The value of sugar-canes at a given plantation or central factory would at first sight appear to vary directly as the amount of saccharine contained in the juice expressed from them varies, and if canes with juice indicating 9° Beaumé be made a basis of value or worth, say at 10s. per ton, then canes with juice indicating

Commercial Values of Sugar-canes.

in degrees Beaumé	10°	9°	8°	7°	6°
and containing in sugar	18·05 %	16·23 %	14·42 %	12·61 %	10·80 %
would be worth per ton	11/1½	10/–	8/10½	7/9½	6/8

But this is not an accurate statement of the commercial value of sugar-canes—that is, of their value for the production of sugar to the planter or manufacturer—because a properly equipped and balanced factory, capable of making 100 tons of sugar per day, for 100 days' crop, from canes giving juice of 9° B., or say 10,000 tons of sugar, at an aggregate expenditure for manufacture (*i.e.* the annual cost of running the factory) of £3 per ton, or £30,000 per annum, will not be able to make as much sugar per day with canes giving juice of 8° B., and will make still less if they yield juice of only 6° B. In practice, the expenses of upkeep for the year and of manufacturing the crop remain the same whether the canes are rich or poor and whether the crop is good or bad, the power of the factory being limited by its power of evaporation. For example, a factory able to evaporate 622 tons of water in 24 hours could treat 1000 tons of canes yielding juice of 9° B., and make therefrom 100 tons of sugar in that time; but this same factory, if supplied with canes giving juice of 6° B., could not treat more than 935 tons of canes in 24 hours, and would only make therefrom 62·2 tons of sugar.

The following table may be useful to planters and central factory owners. It shows the comparative results of working with juice of the degrees of density mentioned above, under the conditions described, for one day of 24 hours, and the real value, as raw material for manufacture, of cane giving juice of 6° B. to 10° B., with their apparent value based solely on the percentage of sugar in the juice. The canes in each case are assumed to contain 88 % of juice and 12 % of fibre, and the extraction by milling to be 75 % of the weight of canes—the evaporative power of the factory being equal to 622 tons per 24 hours. The factory expenses are taken at £30,000 per annum, or £3 per ton on a crop of 10,000 tons (the sugar to cost £8 per ton all told at the factory)—equivalent to £300 per day for the 100 working days of crop time.

Degrees Beaumé.	6°	7°	8°	9°	10°
Tons of canes crushed per day	935·6	956·2	977·4	1000	1023·8
Tons of juice expressed . . .	701·7	717·2	733·1	750	767·9
Tons of water evaporated . .	622	622	622	622	622
Tons of 1st Massecuite . . .	79·7	95·2	111·1	128	145·9
Tons sugar of all classes recovered	62·2	74·3	86·7	100	114·0
Total output of sugar in 100 days. Tons .	6220	7430	8670	10,000	11,400
Total value of all sugars per day at £8 per ton .	£497, 6/–	£594, 4/–	£693, 6/–	£800	£912
Less factory expenses per day .	£300	£300	£300	£300	£300
Leaves for canes crushed . . .	£197, 6/–	£294, 4/–	£393, 6/–	£500	£612
Real value of canes per ton .	4/2⅝	6/2	8/–	10/–	11/11½
Apparent value (see preceding Table) . . .	6/8	7/9½	8/10½	10/–	11/1½

But it is obvious that it would not pay a planter to sell canes at 4s. 2⅝d. a ton instead of at 10s. a ton, any more than it would pay a factory to make only 62·2 tons of sugar in 24 hours, or 6220 tons in the crop of 100 days, instead of 10,000 tons. Hence arises the imperative necessity of good cultivation by the planter, and of circumspection in the purchase and acceptance of canes on the part of the manufacturer.

The details of manufacture of sugar from canes and of sugar from beetroots differ, but there are five operations in the production of the sugar of commerce from either material which are common to both processes. These are:—

1. The extraction of the juice.
2. The purification or defecation of the juice.
3. The evaporation of the juice to syrup point.
4. The concentration and crystallization of the syrup.
5. The curing or preparation of the crystals for the market by separating the molasses from them.

Extraction by Pressure.

Extraction of Juice.—The juice is extracted from canes by squeezing them between rollers. In India at the present day there are thousands of small mills worked by hand, through which the peasant cultivators pass their canes two or three at a time, squeezing them a little, and extracting perhaps a fourth of their weight in juice, from which they make a substance resembling a dirty sweetmeat rather than sugar. In Barbadoes there are still many estates making good Mascabado sugar; but as the juice is extracted from the canes by windmills, and then concentrated in open kettles heated by direct fire, the financial results are disastrous, since nearly half the yield obtainable from the canes is lost. In the best organized modern cane sugar estates as much as 12½ % of the weight of the canes treated is obtained in crystal sugar of high polarizing power, although in Louisiana, where cultivation and manufacture are alike most carefully and admirably carried out, the yield in sugar is only about 7 % of the weight of the canes, and sometimes, but seldom, as much as 9 %. This is due to conditions of climate, which are much less favourable for the formation of saccharine in the canes than in Cuba. The protection afforded to the planters by their government, however, enables them to pursue the industry with considerable profit, notwithstanding the poor return for their labour in saleable produce. As an instance of the influence of climatic conditions combined with high cultivation the cane lands of the Sandwich Islands may be cited. Here the tropical heat is tempered by constant trade winds, there is perfect immunity from hurricanes, the soil is peculiarly suited for cane-growing, and by the use of specially-prepared fertilizers and an ample supply of water at command for irrigation the land yields from 50 to 90 tons of canes per acre, from which from 12 to 14 % of sugar is produced. To secure this marvellous return, with an annual rainfall of 26 in., as much as 52,000,000 gallons of water are pumped per 24 hours from artesian wells on one estate alone. With an inexhaustible supply of irrigation water obtainable, there is no reason why the lands in Upper Egypt, if scientifically cultivated and managed, should not yield as abundantly as those in the Sandwich Islands.

In the Paris Exhibition of 1900 a cane-crushing mill was shown with three rollers 32 in. in diameter by 60 in. long. It is driven by a powerful engine through triple gearing of 42 to 1, and speeded to have a surface velocity of rollers of 15 ft. 9 in. per minute. This mill is guaranteed to crush thoroughly and efficiently from 250 to 300 tons of canes in 24 hours. In Louisiana two mills, set one behind the other, each with three rollers 32 in. in diameter by 78 in. long, and driven by one engine through gearing of 15 to 1, are speeded to have a surface velocity of rollers of 25 ft. 6 in. per minute (or 60% more than that of the French mill described above), and they are efficiently crushing 900 to 1200 tons of canes in 24 hours. In Australia, Demerara, Cuba, Java and Peru *double crushing and maceration* (first used on a commercial scale in Demerara by the late Hon. William Russell) have been generally adopted; and in many places, especially in the Hawaiian Islands, *triple crushing* (*i.e.* passing the canes through three consecutive sets of rollers, in order to extract everything possible of extraction by pressure) is employed. In the south of Spain, in some favoured spots where sugar-canes can be grown, they are submitted even to four successive crushings.

It has been found in practice advantageous to prepare the canes for crushing in the mills, as above described, by passing them through a pair of preparing rolls which are grooved or indented in such manner as to draw in and flatten down the canes, no matter in which way they are thrown or heaped upon the cane-carrier, and thus prepare them for feeding the first mill of the series; thus the work of crushing is carried on uninterruptedly and without constant stoppages from the mills choking, as is often the case when the feed is heavy and the canes are not prepared.

Although it cannot be said that any one system of extraction is the best for all places, yet the following considerations are of general application:—

Yield from Crushing.

a. Whatever pressure be brought to bear upon it, the vegetable or woody fibre of crushed sugar-canes will hold and retain *for the moment* a quantity of moisture equal to its own weight, and in practice 10% more than its own weight; or in other words, 100 lb of the best crushed megass will consist of 47·62 lb of fibre and 52·38 lb of moisture—that is, water with sugar in solution, or juice.

b. Canes vary very much in respect of the quality and also as to the quantity of the juice they contain. The quantity of the juice is the test to which recourse must be had in judging the efficiency of the extraction, while the quality is the main factor to be taken into account with regard to the results of subsequent manufacture.

For the application of the foregoing considerations to practice, the subjoined table has been prepared. It shows the greatest quantity of juice that may be expressed from canes, according to the different proportions of fibre they contain, but without employing maceration or imbibition, to which processes reference is made hereafter. The percentages are percentages of the original weight of the uncrushed canes.

	Per Cent.	Per Cent.	Per Cent.	Per Cent.	Per Cent.	Per Cent.
Percentage of fibre in canes . . .	10	11	12	13	14	15
Percentage of juice in canes . . .	90	89	88	87	86	85
Percentage of juice retained in megass	10	11	12	13	14	15
Percentage of maximum expression.	80	78	76	74	72	70
Percentage of best average expression, in practice.	79	76·9	74·9	72·9	70·6	68·5
Percentage of juice left in megass, in practice . . .	11	12·1	13·2	14·3	15·4	16·5

The British Guiana Planters' Association appointed a sub-committee to report to the West India Commission on the manufacture of sugar, who stated the following:—

With canes containing 12% fibre the following percentages of sugar are extracted from the canes in the form of juice:—

Single crushing	76%
Double crushing	85%
Double crushing with 12% dilution	88%
Triple crushing with 10% dilution	90%
Diffusion with 25% dilution	94%

These results are equivalent to

66·88% extraction for single crushing.
74·80% ,, ,, double crushing.
77·44% ,, ,, double crushing with 12% dilution.
79·20% ,, ,, triple ,, ,, 10% ,,
82·72% ,, ,, diffusion with 25% ,,

Maceration or Imbibition.

To prevent the serious loss of juice left in the megass by even the best double and triple crushing, maceration or imbibition was introduced. The megass coming from the first mill was saturated with steam and water, in weight equal to between 20% and 30% and up to 40% of the original weight of the uncrushed canes. Consequently, after the last crushing the mixture retained by the residual megass was not juice, as was the case when crushing was employed without maceration, but juice mixed with water; and it was found that the loss in juice was reduced by one-half. A further saving of juice was sometimes possible if the market prices of sugar were such as to compensate for the cost of evaporating an increased quantity of added water, but a limit was imposed by the fact that water might be used in excess. Hence in the latest designs for large factories it has been proposed that as much normal juice as can be extracted by double crushing only shall be treated by itself, and that the megass shall then be soused with twice as much water as there is juice remaining in it; after which, on being subjected to a third crushing, it will yield a degraded juice, which would also be treated by itself. It is found that in reducing the juice of these two qualities to syrup, fit to pass to the vacuum pans for cooking to crystals, the total amount of evaporation from the degraded juice is about half that required from the normal juice produced by double crushing.

Mechanical Improvements.

Great improvements have been made in the means of feeding the mills with canes by doing away with hand labour and substituting mechanical feeders or rakes, which by means of a simple steam-driven mechanism will rake the canes from the cane waggons on to the cane-carriers. By the adoption of this system in one large plantation in the West Indies, crushing upwards of 1200 tons of canes per day, the labour of sixty-four hands was dispensed with, and was thus made available for employment in the fields. In Louisiana the use of mechanical feeders is almost universal.

With a view of safeguarding themselves from breakdowns caused by the inequality of feeding, or by the action of malicious persons introducing foreign substances, such as crowbars, bolts, &c., among the canes, and so into the mills, many planters have adopted so-called hydraulic attachments, applied either to the megass roll or the top roll bearings. These attachments, first invented by Jeremiah Howard, and described in the *United States Patent Journal* in 1858, are simply hydraulic rams fitted into the side or top caps of the mill, and pressing against the side or top brasses in such a manner as to allow the side or top roll to move away from the other rolls, while an accumulator, weighted to any desired extent, keeps a constant pressure on each of the rams. An objection to the top cap arrangement is, that if the volume or feed is large enough to lift the top roll from the cane roll, it will simultaneously lift it from the megass roll, so that the megass will not be as well pressed as it ought to be; and an objection to the side cap arrangement on the megass roll as well as to the top cap arrangement is, that in case more canes are fed in at one end of the rolls than at the other, the roll will be pushed out farther at one end than at the other; and though it may thus avoid a breakdown of the rolls, it is apt, in so doing, to break the ends off the teeth of the crown wheels by putting them out of line with one another. The toggle-joint attachment, which is an extremely ingenious way of attaining the same end as the hydraulic attachments, is open to the same objections.

Extraction by Diffusion.

Extraction of cane juice by diffusion (a process more fully described under the head of beetroot sugar manufacture) is adopted in a few plantations in Java and Cuba, in Louisiana and the Hawaiian Islands, and in one or two factories in Egypt; but hitherto, except under exceptional conditions (as at Aska, in the Madras Presidency, where the local price for sugar is three or four times the London price), it would not seem to offer any substantial advantage over double or triple crushing. With the latter system practically as much sugar is obtained from the canes as by diffusion, and the resulting megass furnishes, in a well-appointed factory, sufficient fuel for the crop. With diffusion, however, in addition to the strict scientific control necessary to secure the benefits of the process, fuel—that is, coal or wood—has to be provided for the working off of the crop, since the spent chips or slices from the diffusers are useless for this purpose; although it is true that in some plantations the spent chips have to a certain extent been utilized as fuel by mixing them with a portion of the molasses, which otherwise would have been sold or converted into rum. The best results from extraction by diffusion have been obtained in Java, where there is an abundance of clear, good water; but in the Hawaiian Islands, and in Cuba and Demerara, diffusion has been abandoned on several well mounted estates and replaced by double and triple crushing; and it is not likely to be resorted to again, as the extra cost of working is not compensated by the slight increase of sugar produced. In Louisiana diffusion is successfully worked on two or three large estates; but the general body of planters are shy of using it, although there is no lack of water, the Mississippi being near at hand.

Purification.—The second operation is the coagulation of the albumen, and the separation of it with other impurities from the juice which holds them in suspension or solution. The moment the juice is expelled from the cells of the canes chemical inversion commences, and the sooner it is stopped the better. This is effected by the addition of lime to neutralize the free acid. As cold juice has a greater affinity for lime than hot juice, it is best to treat the juice with lime when cold. This is easily done in liming or measuring tanks of known capacity, into which the juice is run from the mill. The requisite amount of milk of lime set up at 10° Beaumé is then added. Cream of lime of 17° Beaumé is sometimes used, but the weaker solution is preferable, since the proper proportion is more easily adjusted. In Demerara and other places the juice is then heated under pressure up to 220° F. to 250° F. for a few moments, on its way to a steam and juice separator, where the steam due to the superheated juice flashes off, and is either utilized for aiding the steam supplied to the multiple effect evaporators, or for heating cold juice on its way to the main heater, or it is allowed to escape into the atmosphere. The boiling juice is run down into subsiding tanks, where it cools, and at the same time the albumen, which has been suddenly coagulated by momentary exposure to high temperature, falls to the bottom of the tank, carrying with it the vegetable and other matters which were in suspension in the juice. After reposing some time, the clear juice is carefully decanted by means of a pipe fixed by a swivel joint to an outlet in the bottom of the tank, the upper end of the pipe being always kept at the surface of the liquor by a float attached to it. Thus clear liquor alone is run off, and the mud and cloudy liquor at the bottom of the tank are left undisturbed, and discharged separately as required.

Subsiding Tanks.

Continuous Juice Separator.

In Australia a continuous juice separator is generally used, and preferred to ordinary subsiding or filtering tanks. It is a cylindrical vessel about 6 ft. deep, fitted with a conical bottom of about the same depth. Such a vessel is conveniently made of a diameter which will give the cylindrical portion sufficient capacity to hold the juice expressed from the cane-mill in one hour. The hot liquor is conducted downwards in a continuous steady stream by a central pipe to eight horizontal branches, from which it issues into the separator at the level of the junction of the cylindrical and conical portions of the vessel. Since the specific gravity of hot liquor is less than that of cold liquor, and since the specific gravity of the scum and particles of solid matter in suspension varies so slightly with the temperature that practically it remains constant, the hot liquor rises to the top of the vessel, and the scums and particles of solid matter in suspension separate themselves from it and fall to the bottom. By the mode of admission the hot liquor at its entry is distributed over a large area relatively to its volume, and while this is necessarily effected with but little disturbance to the contents of the vessel, a very slow velocity is ensured for the current of ascending juice. In a continuous separator of which the cylindrical portion measures 13 ft. in diameter and 6 ft. deep (a suitable size for treating a juice supply of 4000 to 4500 gallons per hour), the upward current will have a velocity of about 1 inch per minute, and it is found that all the impurities have thus ample time to separate themselves. The clear juice when it arrives at the top of the separator flows slowly over the level edges of a cross canal and passes in a continuous stream to the service tanks of the evaporators or vacuum pan. The sloping sides of the conical bottom can be freed from the coating of scum which forms upon them every two or three hours by two rotatory scrapers, formed of L-irons, which can be slowly turned by an attendant by means of a central shaft provided with a suitable handle. The scums then settle down to the bottom of the cone, whence they are run off to the scum tank. Every twenty-four hours or so the flow of juice may be conveniently stopped, and, after all the impurities have subsided, the superincumbent clear liquor may be decanted by a cock placed at the side of the cone for the purpose, and the vessel may be washed out. These separators are carefully protected by non-conducting cement and wood lagging, and are closed at the top to prevent loss of heat; and they will run for many hours without requiring to be changed, the duration of the run depending on the quality of the liquor treated and amount of impurities therein. Smaller separators of the same construction are used for the treatment of syrup.

Double-bottomed Defecators.

In Cuba, Martinique, Peru and elsewhere the old-fashioned double-bottomed defecator is used, into which the juice is run direct, and there limed and heated. This defecator is made with a hemispherical copper bottom, placed in an outer cast-iron casing, which forms a steam jacket, and is fitted with a cylindrical curb or breast above the bottom. If double-bottomed defecators are used in sufficient number to allow an hour and a half to two hours for making each defecation, and if they are of a size which permits any one of them to be filled up by the cane-mill with juice in ten to twelve minutes, they will make as perfect a defecation as is obtainable by any known system; but their employment involves the expenditure of much high-pressure steam (as exhaust steam will not heat the juice quickly enough through the small surface of the hemispherical inner bottom), and also the use of filter presses for treating the scums. A great deal of skilled superintendence is also required, and first cost is comparatively large. When a sufficient number are not available for a two hours' defecation, it is the practice in some factories to skim off the scums that rise to the top, and then boil up the juice for a few minutes and skim again, and, after repeating the operation once or twice, to run off the juice to separators or subsiders of any of the kinds previously described. In Java and Mauritius, where very clean canes are grown, double-bottomed defecators are generally used, and to them, perhaps as much as to the quality of the canes, may be attributed the very strong, fine sugars made in those islands. They are also employed in Egypt, being remnants of the plant used in the days when the juice passed through bone-black before going to the evaporators.

Continuous Defecation.

A modification of the system of double-bottom defecators has lately been introduced with considerable success in San Domingo and in Cuba, by which a continuous and steady discharge of clear defecated juice is obtained on the one hand, and on the other a comparatively hard dry cake of scum or cachaza, and without the use of filter presses. These results are brought about by adding to the cold juice as it comes from the mill the proper proportion of milk of lime set up at 8° B., and then delivering the limed juice in a constant steady stream as near the bottom of the defecator as possible; it is thus brought into immediate contact with the heating surface and heated once for all before it ascends, with the result of avoiding the disturbance caused in the ordinary defecator by pouring cold juice from above on to the surface of the heated juice, and so establishing down-currents of cold juice and up-currents of hot juice. In the centre of the defecator an open-topped cylindrical vessel is placed, with its bottom about 6 in. above the bottom of the defecator and its top about 12 in. below the top of the defecator. In this vessel is placed the short leg of a draw-off siphon, reaching to nearly the bottom. The action of the moderate heat, 210° F., on the limed juice causes the albumen in it to coagulate; this rising to the surface collects the cachazas, which form and float thereon. The clear juice in the meantime flows over the edge of the cylindrical vessel without disturbance and finds its way out by the short leg of the siphon, and so passes to the canal for collecting the defecated juice. The admission of steam must be regulated with the greatest nicety, so as to maintain an equable temperature, 208° to 210° F., hot enough to act upon the albumen and yet not enough to cause ebullition or disturbance in the juice, and so prevent a proper separation of the cachazas. This is attained by the aid of a copper pipe, 4 in. in diameter, which follows the curve of the hemispherical bottom, and is fitted from one side to the other of the defecator; one end is entirely closed, and the other is connected by a small pipe to a shallow circular vessel outside the defecator, covered with an india-rubber diaphragm, to the centre of which is attached a light rod actuating a steam throttle-valve, and capable of being adjusted as to length, &c. The copper pipe and circular vessel are filled with cold water, which on becoming heated by the surrounding juice expands, and so forces up the india-rubber diaphragm and shuts off the steam. By adjusting the length of the connecting rod and the amount of water in the vessel, the amount of steam admitted can be regulated to a nicety. To make this apparatus more perfectly automatic, an arrangement for continually adding to and mixing with the juice the proper proportion of milk of lime has been adapted to it; and although it may be objected that once the proportion has been determined no allowance is made for the variation in the quality of the juice coming from the mill owing to the variations that may occur in the canes fed into the mills, it is obviously as easy to vary the proportion with the automatic arrangement from time to time as it is to vary in each separate direction, if the man in charge will take the trouble to do so, which he very seldom does with the ordinary defecators, satisfying himself with testing the juice once or twice in a watch. The scums forming on the top of the continuous defecator become so hard and dry that they have to be removed from time to time with a specially constructed instrument like a flat spade with three flat prongs in front. These scums are not worth passing through the filter presses, and are sent to the fields direct as manure.

Treatment of the Scums.

The scums separated from the juice by ordinary defecation entangle and carry away with them a certain amount of the juice with its contained saccharine. In some factories they are collected in suitable tanks, and steam is blown into them, which further coagulates the albuminous particles. These in their upward passage to the top, where they float, free themselves from the juice, which they leave below them comparatively clear. The juice is then drawn off and pumped up to one of the double-bottomed defecators and redefecated, or, where juice-heaters have been used instead of defecators, the scums from the separators or subsiders are heated and forced through filter presses, the juice expressed going to the evaporators and the scum cakes formed in the filter presses to the fields as manure.

In diffusion plants the milk of lime is added, in proper proportion, in the cells of the diffusion battery, and the chips or slices themselves act as a mechanical filter for the juice; while in the Sandwich Islands coral-sand filters have been employed for some years, in addition to the chips, to free the juice from impurities held in mechanical suspension. In Germany very similar filters have also been used, pearl-quartz gravel taking the place of coral sand, which it closely resembles. In Mexico filters filled with dry powdered megass have been found very efficient for removing the large quantity of impurities contained in the juice expressed from the very vigorous but rank canes grown in that wonderfully fertile country, but unless constant care is taken in managing them, and in changing them at the proper time, there is great risk of inversion taking place, with consequent loss of sugar.

After the juice has been defecated or purified by any of the means above mentioned it is sent to the evaporating apparatus, hereinafter described, where it is concentrated to 26° or 28° Beaumé, and is then conducted in a continuous stream either into the service tanks of the vacuum pan, if dark sugars are required, or, if a better colour is wanted, into clarifiers. The latter are circular or rectangular vessels, holding from 500 to 1500 gallons each, according to the capacity of the factory, and fitted with steam coils at the bottom and skimming troughs at the top. In them the syrup is quickly brought up to the boil and skimmed for about five minutes, when it is run off to the service tanks of the vacuum pans. The heat at which the syrup boils in the clarifiers, 220° F., has the property of separating a great deal of the gum still remaining in it, and thus cleansing the solution of sugar and water for crystallization in the vacuum pans; and if after skimming the syrup is run into separators or subsiders of any description, and allowed to settle down and cool before being drawn into the vacuum pan for crystallization, this cleansing process will be more thorough and the quality of the final product will be improved. Whether the improvement will be profitable or not to the planter or manufacturer depends on the market for the sugar, and on the conditions of foreign tariffs, which are not infrequently hostile.

Evaporation of the Juice to Syrup.—The third operation is the concentration of the approximately pure, but thin and watery, juice to syrup point, by driving off a portion of the water in vapour through some system of heating and evaporation. Since on an average 70% by measurement of the normal defecated cane juice has to be evaporated in order to reduce it to syrup ready for final concentration and crystallization in the vacuum pan, and since to attain the same end as much as 90 to 95% of the volume of mixed juices has to be evaporated when maceration or imbibition is employed, it is clear that some more economical mode of evaporation is necessary in large estates than the open-fire batteries still common in Barbados and some of the West Indian islands, and in small haciendas in Central America and Brazil, but seldom seen elsewhere. With open-fire batteries for making the syrup, which was afterwards finished in the vacuum pan, very good sugar was produced, but at a cost that would be ruinous in to-day's markets.

In the best days of the so-called Jamaica Trains in Demerara, three-quarters of a ton of coal in addition to the megass was burned per ton of sugar made, and with this for many years planters were content, because they pointed to the fact that in the central factories, then working in Martinique and Guadeloupe, with charcoal filters and triple-effect evaporation, 750 kilos of coal in addition to the megass were consumed to make 1000 kilos of sugar. All this has now been changed. It is unquestionably better and easier to evaporate *in vacuo* than in an open pan, and with a better system of firing, a more liberal provision of steam generators, and multiple-effect evaporators of improved construction, a far larger yield of sugar is obtained from the juice than was possible of attainment in those days, and the megass often suffices as fuel for the crop.

Multiple-Effect Evaporators.

The multiple-effect evaporator, originally invented and constructed by Norberto Rilleux in New Orleans in 1840, has undergone many changes in design and construction since that year. The growing demand for this system of evaporation for application in many other industries besides that of sugar has brought to the front a large number of inventors. Forgetful or ignorant of the great principle announced and established by Rilleux, they have mostly devoted their energies and ingenuity to contriving all sorts of complicated arrangements to give the juice the density required, by passing and repassing it over the heating surface of the apparatus, the saving of a few square feet of which would seem to have been their main object. In some instances the result has been an additional and unnecessary expenditure of high-pressure steam, and in all the well-known fact—of the highest importance in this connexion—appears to have been disregarded, that the shorter the time the juice is exposed to heat the less inversion will take place in it, and therefore the less will be the loss of sugar. But this competition among inventors, whatever the incentive, has not been without benefit, because to-day, by means of very simple improvements in details, such as the addition of circulators and increased area of connexions, what may be taken to be the standard type of multiple-effect evaporator (that is to say, vertical vacuum pans fitted with vertical heating tubes, through which passes the liquor to be treated, and outside of which the steam or vapour circulates) evaporates nearly double the quantity of water per square foot of heating surface per hour which was evaporated by apparatus in use so recently as 1885—and this without any increase in the steam pressure. That evaporation *in vacuo*, in a multiple-effect evaporator, is advantageous by reason of the increased amount of sugar obtained from a given quantity of juice, and by reason of economy of fuel, there is no doubt, but whether such an apparatus should be of double, triple, quadruple or quintuple effect will depend very much on the amount of juice to be treated per day, and the cost of fuel. Thus, supposing that 1000 lb of coal were required to work a single vacuum pan, evaporating, say, 6000 lb of water in a given time, then 500 lb of coal would be required for a double-effect apparatus to do the same work, 333 lb for a triple effect, 250 for a quadruple effect, and 200 lb for a quintuple effect. In some places where coal costs 60s. a ton, and where steam is raised by coal, as in a beetroot factory, it might pay to adopt a quintuple-effect apparatus, but on a cane-sugar estate, where the steam necessary for the evaporator is raised by burning the megass as fuel, and is first used in the engines working the mills, the exhaust alone passing to the evaporator, there would be very little, if any, advantage in employing a quadruple effect instead of a triple effect, and practically none at all in having a quintuple-effect apparatus, for the interest and sinking fund on the extra cost would more than counterbalance the saving in fuel.

With the juice of some canes considerable difficulty is encountered in keeping the heating surfaces of the evaporators clean and free from incrustations, and cleaning by the use of acid has to be resorted to. In places where work is carried on day and night throughout the week, the standard type of evaporator lends itself more readily to cleaning operations than any other. It is obviously easier to brush out and clean vertical tubes open at both ends, and about 6 ft. long, on which the scale has already been loosened by the aid of boiling with dilute muriatic acid or a weak solution of caustic soda in water, than it is to clean either the inside or the outside of horizontal tubes more than double the length. This consideration should be carefully remembered in the future by the planter who may require an evaporator and by the engineer who may be called upon to design or construct it, and more especially by a constructor without practical experience of the working of his constructions.

Concentration and Crystallization.—The defecated cane juice, having lost about 70% of its bulk by evaporation in the multiple-effect evaporator, is now syrup, and ready to enter the vacuum pan for further concentration and crystallization.

Howard's Vacuum Pan.

In a patent (No. 3607, 1812) granted to E. C. Howard it is stated, among other things, that "water dissolves the most uncrystallizable in preference to that which is most crystallizable sugar," and the patentee speaks of "a discovery I have made that no solution, unless highly concentrated, of sugar in water can without material injury to its colouring and crystallizing power, or to both, be exposed to its boiling temperature during the period required to evaporate such solution to the crystallizing point." He stated that "he had made a magma of sugar and water at atmospheric temperature, and heated the same to 190° or 200° F. in a water or steam bath, and then added more sugar or a thinner magma, and the whole being then in a state of imperfect fluidity, but so as to close readily behind the stirrer, was filled into moulds and purged" (drained). "I do further declare," he added, "that although in the application of heat to the refining of sugar in my said invention or process I have stated and mentioned the temperature of about 200° F. scale as the heat most proper to be used and applied in order to secure and preserve the colour and crystallizability of the sugars, and most easily to be obtained with precision and uniformity by means of the water bath and steam bath, yet when circumstances or choice may render the same desirable I do make use of higher temperatures, although less beneficial." Howard at any rate saw clearly what was one of the indispensable requisites for the economical manufacture of fine crystal sugar of good colour—the treatment of saccharine solutions at temperatures very considerably lower than 212° F., which is the temperature of water boiling at normal atmospheric pressure. Nor was he long in providing means for securing these lower temperatures. His patent (No. 3754 of 1813) describes the closed vacuum pan and the air pump with condenser for steam by injection, the use of a thermometer immersed in the solution in the pan, and a method of ascertaining the density of the solution with a proof stick, and by observations of the temperature at which, while fluid and not containing grain, it could be kept boiling under different pressures shown by a vacuum gauge. A table is also given of boiling points from 115° F. to 175° F., corresponding to decimal parts of an inch of mercury of the vacuum gauge. Since Howard published his invention the vacuum pan has been greatly improved and altered in shape and power, and especially of recent years, and the advantages of concentrating *in vacuo* having been acknowledged, the system has been adopted in many other industries, and crowds of inventors have turned their attention to the principle. In endeavouring to make a pan of less power do as much and as good work as one of greater power, they have imagined many ingenious mechanical contrivances, such as currents produced mechanically to promote evaporation and crystallization, feeding the pan from many points in order to spread the feed equally throughout the mass of sugar being cooked, and so on. All their endeavours have obtained at best but a doubtful success, for they have overlooked the fact that to evaporate a given weight of water from the syrup in a vacuum pan at least an equal weight (or in practice about 15% more) of steam must be condensed, and the first cost of mechanical agitators, together with the expenditure they involve for motive power and maintenance, must be put against the slight saving in the heating surface effected by their employment. On the other hand, the advocates of admitting the feed into a vacuum pan in many minute streams appeal rather to the ignorant and incompetent sugar-boiler than to a man who, knowing his business thoroughly, will boil 150 tons of hot raw sugar in a pan in a few hours, feeding it through a single pipe and valve 10 in. in diameter. Nevertheless, it has been found in practice, when syrups with low quotient of purity and high quotient of impurity are being treated, injecting the feed at a number of different points in the pan does reduce the time required to boil the pan, though of no practical advantage with syrups of high quotient of purity and free from the viscosity which impedes circulation and therefore quick boiling. Watt, when he invented the steam engine, laid down the principles on which it is based, and they hold good to the present day. So also the principles laid down by Howard with respect to the vacuum pan hold good to-day: larger pans have been made and their heating surface has been increased, but it has been found by practice now, as it was found then, that an ordinary worm or coil 4 in. in diameter and 50 ft. long will be far more efficient per square foot of surface than a similar coil 100 ft. long. Thus the most efficient vacuum pans of the present day are those which have their coils so arranged that no portion of them exceeds 50 or 60 ft. in length; with such coils, and a sufficient annular space in the pan free from obstruction, in order to allow a natural down-current of the cooking mass, while an up-current all round is also naturally produced by the action of the heated worms or coils, rapid evaporation and crystallization can be obtained, without any mechanical adjuncts to require attention or afford excuse for negligence.

The choice of the size of the crystals to be produced in a given pan depends upon the market for which they are intended. It is of course presupposed that the juice has been properly defecated, because without this no amount of skill and knowledge in cooking in the pan will avail; the sugar resulting must be bad, either in colour or grain, or both, and certainly in polarizing power. If a very large firm grain like sugar-candy is required the syrup when first brought into the pan must be of low density, say 20° to 21° Beaumé, but if a smaller grain be wanted it can easily be obtained from syrup of 27° to 28° Beaumé. On some plantations making sugar for particular markets and use in refineries it is the custom to make only one class of sugar, by boiling the molasses produced by the purging of one strike with the sugar in the next strike. On other estates the second sugars, or sugars produced from boiling molasses alone, are not purged to dryness, but when sufficiently separated from their mother-liquor are mixed with the defecated juice, thereby increasing its saccharine richness, and after being converted into syrup in the usual manner are treated in the vacuum pan as first sugars, which in fact they really are.

In certain districts, notably in the Straits Settlements, syrup is prepared as described above for crystallization in a vacuum pan, but instead of being cooked *in vacuo* it is slowly boiled up in open double-bottom pans. These pans are sometimes heated by boiling oil, with the idea that under such conditions the sugar which is kept stirred all the time as it thickens cannot be burnt or caramelized; but the same object can be attained more economically with steam of a given pressure by utilizing its latent heat. The sugar thus produced, by constant stirring and evaporation almost to dryness, forms a species of small-grained concrete. It is called "basket sugar," and meets with a brisk sale, at remunerative prices, among the Chinese coolies; and as the sugar as soon as cooled is packed ready for market, without losing any weight by draining, this branch of sugar-making is a most lucrative one wherever there is sufficient local demand. Very similar kinds of sugar are also produced for local consumption in Central America and in Mexico, under the names of "Panela" and "Chancaca," but in those countries the sugar is generally boiled in pans placed over special fire-places, and the factories making it are on a comparatively small scale, whereas in the Straits Settlements the "basket sugar" factories are of considerable importance, and are fitted with the most approved machinery.

Curing or Preparation of Crystals for the Market.—The crystallized sugar from the vacuum pan has now to be separated from the molasses or mother-liquor surrounding the crystals. In some parts of Mexico and Central America this separation is still effected by running the sugar into conical moulds, and placing on the top a layer of moist clay or earth which has been kneaded in a mill into a stiff paste. The moisture from the clay, percolating through the mass of sugar, washes away the adhering molasses and leaves the crystals comparatively free and clear. It may be noted that sugar that will not purge easily and freely with clay will not purge easily and freely in centrifugals. But for all practical purposes the system of claying sugar is a thing of the past, and the bulk of the sugar of commerce is now purged in centrifugals, as indeed it has been for many years. The reason is obvious. The claying system involved the expense of large curing houses and the employment of many hands, and forty days at least were required for completing the operation and making the sugar fit for the market, whereas with centrifugals sugar cooked to-day can go to market to-morrow, and the labour employed is reduced to a minimum.

When Cuba was the chief sugar-producing country making clayed sugars it was the custom (followed in refineries and found advantageous in general practice) to discharge the strike of crystallized sugar from the vacuum pan into a receiver heated below by steam, and to stir the mass for a certain time, and then distribute it into the moulds in which it was afterwards clayed. When centrifugals were adopted for purging the whole crop (they had long been used for curing the second or third sugars), the system then obtaining of running the sugar into wagons or coolers, which was necessary for the second and third sugars cooked only to string point, was continued, but latterly "crystallization in movement," a development of the system which forty years ago or more existed in refineries and in Cuba, has come into general use, and with great advantage, especially where proprietors have been able to erect appropriate buildings and machinery for carrying out the system efficiently. The vacuum pan is erected at a height which commands the crystallizers, each of which will, as in days gone by in Cuba, hold the contents of the pan, and these in their turn are set high enough to allow the charge to fall into the feeding-trough of the centrifugals, thus obviating the necessity of any labour to remove the raw sugar from the time it leaves the vacuum pan to the time it falls into the centrifugals. For this reason alone, and without taking into consideration any increase in the yield of sugar brought about by "crystallization in movement," the system is worthy of adoption in all sugar factories making crystal sugar.

Crystallizers. The crystallizers are long, horizontal, cylindrical or semi-cylindrical vessels, fitted with a strong horizontal shaft running from end to end, which is kept slowly revolving. The shaft carries arms and blades fixed in such a manner that the mass of sugar is quietly but thoroughly moved, while at the same time a gentle but sustained evaporation is produced by the continuous exposure of successive portions of the mass to the action of the atmosphere. Thus also the crystals already formed come in contact with fresh mother-liquor, and so go on adding to their size. Some crystallizers are made entirely cylindrical, and are connected to the condenser of the vacuum pan; in order to maintain a partial vacuum in them, some are fitted with cold-water pipes to cool them and with steam pipes to heat them, and some are left open to the atmosphere at the top. But the efficiency of all depends on the process of almost imperceptible yet continuous evaporation and the methodical addition of syrup, and not on the idiosyncrasies of the experts who manage them; and there is no doubt that in large commercial processes of manufacture the simpler the apparatus used for obtaining a desired result, and the more easily it is understood, the better it will be for the manufacturer. The sugar made from the first syrups does not require a crystallizer in movement to prepare it for purging in the centrifugals, but it is convenient to run the strike into the crystallizer and so empty the pan at once and leave it ready to commence another strike, while the second sugars will be better for twenty-four hours' stirring and the third sugars for forty-eight hours' stirring before going to the centrifugals. To drive these machines electricity has been applied, with indifferent success, but they have been very efficiently driven, each independently of the others in the set, by means of a modification of a Pelton wheel, supplied with water under pressure from a pumping engine. A comparatively small stream strikes the wheel with a pressure equivalent to a great head, say 300 ft., and as the quantity of water and number of jets striking the wheel can be regulated with the greatest ease and nicety, each machine can without danger be quickly brought up to its full speed when purging high-class sugars, or allowed to run slowly when purging low-class sugars, until the heavy, gummy molasses have been expelled; and it can then be brought up to its full speed for finally drying the sugar in the basket, a boon which all practical sugar-makers will appreciate. The water forced by the force-pump against the Pelton wheels returns by a waste-pipe to the tank, from which the force-pump takes it again.

Recent Progress.—The manufacture of cane sugar has largely increased in volume since the year 1901–1902. This, apart from the effect of the abolition of the sugar bounties, has been mainly the result of the increased employment of improved processes, carried on in improved apparatus, under skilled supervision, and with due regard to the importance of the chemical aspects of the work.

Central Factories. Numerous central factories have been erected in several countries with plant of large capacity, and many of them work day and night for six days in the week. There were 173 of these factories working in Cuba in 1908–1909, among which the "Chaparra," in the province of Oriente, turned out upwards of 69,000 tons of sugar in the crop of about 20 weeks, and the "Boston" had an output of about 61,000 tons in the same time. Of the 178 factories at work in Java in 1908–1909, nearly all had most efficient plant for treating the excellent canes grown in that favoured island. (See *Jaarboek voor suikerfabrikanten op Java, 13e Jaargang 1908–1909*, pp. 22–61, Amsterdam, J. H. de Bussy.) The severance of the agricultural work, *i.e.* cane-growing, from the manufacturing work, sugar-making, must obviously conduce to better and more profitable work of both kinds.

The use of multiple-effect evaporation made it possible to raise the steam for all the work required to be done in a well-equipped factory, making crystals, under skilful management, by means of the bagasse alone proceeding from the canes ground, without the aid of other fuel. The bagasse so used is now commonly taken straight from the cane mill to furnaces specially designed for burning it, in its moist state and without previous drying, and delivering the hot gases from it to suitable boilers, such as those of the multitubular type or of the water-tube type. The value of fresh bagasse, or as it is often called "green" bagasse, as fuel varies with the kind of canes from which it comes, with their treatment in the mill, and with the skill used in firing; but it may be stated broadly that 1 lb of fresh bagasse will produce from 1½ lb to 2¼ lb of steam, according to the conditions.

Green Bagasse as Fuel.

The use of preparing rolls with corrugations, to crush and equalize the feed of canes to the mill, or to the first of a series of mills, has become general. The Krajewski crusher has two such steel rolls, with V-shaped corrugations extending longitudinally across them. These rolls run at a speed about 30% greater than the speed of the first mill, to which they deliver the canes well crushed and flattened, forming a close mat of pieces of cane 5 to 6 in. long, so that the subsequent grinding can be carried on without the stoppages occasioned by the mill choking with a heavy and irregular feed. The crusher is preferably driven by an independent engine, but with suitable gearing it can be driven by the mill engine. The Krajewski crusher was invented some years ago by a Polish engineer resident in Cuba, who took out a patent for it and gave it his name. The patent has expired. The increase in the output for a given time obtained by the use of the Krajewski crusher has been estimated at 20 to 25% and varies with the quality of the canes; while the yield of juice or extraction is increased by 1 or 2%.

Extraction of Juice.

The process of continuous defecation which was introduced into Cuba from Santo Domingo about 1900 had by 1910 borne the test of some ten years' use with notable success. The Hatton defecator, which is employed for working it, has been already described, but it may be mentioned that the regulation of the admission of steam is now simplified and secured by a patent thermostat—a self-acting apparatus in which the unequal expansion of different metals by heat actuates, through compressed air, a diaphragm which controls the steam stop-valve—and by this means a constant temperature of 210° F. (98·8° C.) is maintained in the juice within the defecator during the whole time it is at work.

Purification.

Earthy matter and other matter precipitated and fallen on the copper double bottom may be dislodged by a slowly revolving scraper—say every twelve hours—and ejected through the bottom discharge cock; and thus the heating surface of the copper bottom will be kept in full efficiency. With ordinary care on the part of the men in charge Hatton defecators will work continuously for several days and nights, and the number required to deal with a given volume of juice is half the number of ordinary defecators of equal capacity which would do the same work; for it must be borne in mind that an ordinary double-bottomed defecator takes two hours to deliver its charge and be in readiness to receive a fresh charge, *i.e.* 20 minutes for filling and washing out after emptying; 60 minutes for heating up and subsiding; and 40 minutes for drawing off the defecated juice, without agitating it. Apart from increased yield in sugar of good quality, we may sum up the advantages procurable from the use of Hatton defecators as follows: cold liming; heating gently to the temperature required to coagulate the albumen and not beyond it, whereby disturbance would ensue; the continuous separation of the scums; the gradual drying of the scums so as to make them ready for the fields, without carrying away juice or requiring treatment in filter presses; and the continuous supply of hot defecated juice to the evaporators, without the use of subsiding tanks or eliminators; and, finally, the saving in expenditure on plant, such as filter presses, &c., and wages.

Beetroot Sugar Manufacture.—The sugar beet is a cultivated variety of *Beta maritima* (nat. ord. Chenopodiaceae), other varieties of which, under the name of mangold or mangel-wurzel, are grown as feeding roots for cattle.

About 1760 the Berlin apothecary Marggraff obtained in his laboratory, by means of alcohol, 6·2% of sugar from a white variety of beet and 4·5% from a red variety. At the present day, thanks to the careful study of many years, the improvements of cultivation, the careful selection of seed and suitable manuring, especially with nitrate of soda, the average beet worked up contains 7% of fibre and 93% of juice, and yields in Germany 12·79% and in France 11·6% of its weight in sugar. In Great Britain in 1910 the cultivation of beet for sugar was being seriously undertaken in Essex, as the result of careful consideration during several years. The pioneer experiments on Lord Denbigh's estates at Newnham Paddox, in Warwickshire, in 1900, had produced excellent results, both in respect of the weight of the beets per acre and of the saccharine value and purity of the juice. The average weight per acre was over 25½ tons, and the mean percentage of pure sugar in the juice exceeded 15½. The roots were grown under exactly the same cultivation and conditions as a crop of mangel-wurzel—that is to say, they had the ordinary cultivation and manuring of the usual root crops. The weight per acre, the saccharine contents of the juice, and the quotient of purity compared favourably with the best results obtained in Germany or France, and with those achieved by the Suffolk farmers, who between 1868 and 1872 supplied Mr Duncan's beetroot sugar factory at Lavenham; for the weight of their roots rarely reached 15 tons per acre, and the percentage of sugar in the juice appears to have varied between 10 and 12. On the best-equipped and most skilfully managed cane sugar estates, where the climate is favourable for maturing the cane, a similar return is obtained. Therefore, roughly speaking, one ton of beetroot may be considered to-day as of the same value as one ton of canes; the value of the refuse chips in one case, as food for cattle, being put against the value of the refuse bagasse, as fuel, in the other. Before beetroot had been brought to its present state of perfection, and while the factories for its manipulation were worked with hydraulic presses for squeezing the juice out of the pulp produced in the raperies, the cane sugar planter in the West Indies could easily hold his own, notwithstanding the artificial competition created and maintained by sugar bounties. But the degree of perfection attained in the cultivation of the roots and their subsequent manipulation entirely altered this situation and brought about the crisis in the sugar trade referred to in connexion with the bounties (see *History* below) and dealt with in the Brussels convention of 1902.

In beetroot sugar manufacture the operations are washing, slicing, diffusing, saturating, sulphuring, evaporation, concentration and curing.

Slicing.—The roots are brought from the fields by carts, canals and railways. They are weighed and then dumped into a washing machine, consisting of a large horizontal cage, submerged in water, in which revolves a horizontal shaft carrying arms. The arms are set in a spiral form, so that in revolving they not only stir the roots, causing them to rub against each other, but also force them forward from the receiving end of the cage to the other end. Here they are discharged (washed and freed from any adherent soil) into an elevator, which carries them up to the top of the building and delivers them into a hopper feeding the slicer. Slicers used to be constructed with iron disks about 33 to 40 in. diameter, which were fitted with knives and made 140 to 150 revolutions per minute, under the hopper which received the roots. This hopper was divided into two parts by vertical division plates, against the bottom edge of which the knives in the disk forced the roots and sliced and pulped them. Such machines were good enough when the juice was expelled from the small and, so to speak, chopped slices and pulp by means of hydraulic presses. But hydraulic presses have now been abandoned, for the juice is universally obtained by diffusion, and the small slicers have gone out of use, because the large amount of pulp they produced in proportion to slices is not suitable for the diffusion process, in which evenly cut slices are required, which present a much greater surface with far less resistance to the diffusion water. Instead of the small slicers, machines made on the same principle, but with disks 7 ft. and upwards in diameter, are used. Knives are arranged around their circumference in such a way that the hopper feeding them presents an annular opening to the disk, say 7 ft. outside diameter and 5 ft. inside, with the necessary division plates for the knives to cut against, and instead of making 140 to 150 revolutions the disks revolve only 60 to 70 times per minute. Such a slicer is capable of efficiently slicing 300,000 kilos of roots in twenty-four hours, the knives being changed four times in that period, or oftener if required, for it is necessary to change them the moment the slices show by their rough appearance that the knives are losing their cutting edges.

Diffusion.—The diffusion cells are closed, vertical, cylindrical vessels, holding generally 60 hectolitres, or 1320 gallons, and are arranged in batteries of 12 to 14. Sometimes the cells are erected in a circle, so that the spout below the slicing machine revolving above them with a corresponding radius can discharge the slices into the centre of any of the cells. In other factories the cells are arranged in lines and are charged from the slicer by suitable telescopic pipes or other convenient means. A circular disposition of the cells facilitates charging by the use of a pipe rotating above them, but it renders the disposal of the hot spent slices somewhat difficult and inconvenient. The erection of the cells in straight lines may cause some little complication in charging, but it allows the hot spent slices to be discharged upon a travelling band which takes them to an elevator, an arrangement simpler than any which is practicable when the cells are disposed in a circle. Recently, however, a well-known sugar maker in Germany has altered his battery in such manner that instead of having to open a large door below the cells in order to discharge them promptly, he opens a comparatively small valve and, applying compressed air at the top of the cell, blows the whole contents of spent slices up a pipe to the drying apparatus, thus saving not only a great deal of time but also a great deal of labour of a kind which is both arduous and painful, especially during cold weather. The slices so blown up, or elevated, are passed through a mill which expels the surplus water, and are then pressed into cakes and dried until they hold about 12% of water and 88% of beet fibre. These cakes, sold as food for cattle, fetch as much as £4 per ton in Rumania, where four or five beetroot factories are now at work. A cell when filled with fresh slices becomes the head of the battery, and where skilled scientific control can be relied upon to regulate the process, the best and most economical way of heating the slices, previous to admitting the hot liquor from the next cell, is by direct steam; but as the slightest inattention or carelessness in the admission of direct steam might have the effect of inverting sugar and thereby causing the loss of some portion of saccharine in the slices, water heaters are generally used, through which water is passed and heated up previous to admission to the freshly-filled cell. When once a cell is filled up and the slices are warmed through, the liquor from the adjoining cell, which hitherto has been running out of it to the saturators, is turned into the new cell, and beginning to displace the juice from the fresh slices, runs thence to the saturators. When the new cell comes into operation and becomes the head of the battery, the first or tail cell is thrown out, and number two becomes the tail cell, and so the rounds are repeated; one cell is always being emptied and one filled or charged with slices and heated up, the latter becoming the head of the battery as soon as it is ready.

Saturation.—The juice, previously treated with lime in the diffusion battery, flows thence into a saturator. This is a closed vessel, into which carbonic acid gas (produced as described hereafter) is forced, and combining with the lime in the juice forms carbonate of lime. The whole is then passed through filter presses, the clear juice being run off for further treatment, while the carbonate of lime is obtained in cakes which are taken to the fields as manure. The principal improvement made of recent years in this portion of the process has been the construction of pipes through which the carbonic acid gas is injected into the juice in such a manner that they can be easily withdrawn and a clean set substituted. The filter presses remain substantially unchanged, although many ingenious but slight alterations have been made in their details. The juice, which has now become comparatively clear, is again treated with lime, and again passed through a saturator and filter presses, and comes out still clearer than before. It is then treated with sulphurous acid gas, for the purpose of decolorization, again limed to neutralize the acid, and then passed through a third saturator wherein all traces of lime and sulphur are removed.

A process for purifying and decolorizing the juice expressed from beetroots by the addition of a small quantity of manganate of lime (20 to 50 grammes per hectolitre of juice), under the influence of an electric current, was worked with considerable success in a sugar factory in the department of Seine-et-Marne in the year 1900–1901. A saving of 40% is stated to be effected in lime. The use of sulphurous acid gas is entirely abandoned, and instead of three carbonatations with corresponding labour and plant only one is required. The coefficient of purity is increased and the viscosity of the juice diminished. The total saving effected is stated to be equivalent to 3 francs per ton of beetroot worked up. This system is also being tried on a small scale with sugar-cane juice in the West Indies. If by this process a more perfect defecation and purification of the juice is obtained, it will no doubt be highly beneficial to the cane planter, though no great economy in lime can be effected, because but very little is used in a cane factory in comparison with the amount used in a beet factory.

Evaporation and Crystallization.—The clear juice thus obtained is evaporated in a multiple-effect evaporator and crystallized in a vacuum pan, and the sugar is purged in centrifugals. From the centrifugal the sugar is either turned out without washing as raw sugar, only fit for the refinery, or else it is well washed with a spray of water and air until white and dry, and it is then offered in the market as refined sugar, although it has never passed through animal charcoal (bone-black). The processes of evaporation and concentration are carried on as they are in a cane sugar factory, but with this advantage, that the beet solutions are freer from gum and glucose than those obtained from sugar-canes, and are therefore easier to cook.

Curing.—There are various systems of purging refined, or so-called refined, sugar in centrifugals, all designed with a view of obtaining the sugar in lumps or tablets, so as to appear as if it had been turned out from moulds and not from centrifugals, and great ingenuity and large sums of money have been spent in perfecting these different systems, with more or less happy results. But the great achievement of recent manufacture is the production, without the use of animal charcoal, of a cheaper, but good and wholesome article, in appearance equal to refined sugar for all intents and purposes, except for making preserves of fruits in the old-fashioned way. The wholesale jam manufacturers of the present day use this sugar; they boil the jam *in vacuo* and secure a product that will last a long time without deteriorating, but it lacks the delicacy and distinctive flavour of fruit preserved by a careful housekeeper, who boils it in an open pan with cane sugar to a less density, though exposed for a short time to a greater heat.

Carbonatation.—The carbonic acid gas injected into the highly limed juice in the saturators is made by the calcination of limestone in a kiln provided with three cleaning doors, so arranged as to allow the lime to be removed simultaneously from them every six hours. The gas generated in the kiln is taken off at the top by a pipe to a gas-washer. In this it passes through four sheets of water, by which it is not only freed from any dust and dirt that may have come over with it from the kiln, but is also cooled to a temperature which permits an air-pump to withdraw the gas from the kiln, through the gas-washer, and force it into the saturators, without overheating. In some factories for refining sugar made from beet or canes this system of carbonatation is used, and enables the refiner to work with syrups distinctly alkaline and to economize a notable amount of animal charcoal.

Refining.—Briefly, sugar-refining consists of melting raw or unrefined sugar with water into a syrup of 27° to 28° Beaumé, or 1230 specific gravity, passing it through filtering cloth to remove the sand and other matters in mechanical suspension, and then through animal charcoal to remove all traces of colouring matter and lime, thus producing a perfectly clear white syrup, which, cooked in the vacuum pan and crystallized, becomes the refined sugar of commerce.

Melting Pans.—The melting pans are generally circular vessels, fitted with a perforated false bottom, on which the sugar to be melted is dumped. The pans are provided with steam worms to keep the mass hot as required, and with mechanical stirrers to keep it in movement and thoroughly mixed with the water and sweet water which are added to the sugar to obtain a solution of the specific gravity desired. Any sand or heavy matter in suspension is allowed to fall to the bottom of the pan into the "sandbox" before the melted sugar is run off to the cloth filters. In a process employed with great success in some refineries the raw sugars are washed before being melted, and thus a purer article is obtained for subsequent treatment. In this process the raw sugar is mixed with a small amount of syrup so as to form a suitable magma, and is then run into a continuous centrifugal, where it is sufficiently washed, and from which it runs out, comparatively clean, into the melting pans described above.

Filters.—Taylor bag filters are generally used for clearing the melted liquor of its mechanical impurities. They were introduced years ago by the man whose name they still retain, but they are very different in construction to-day from what they were when first employed. They consist of tanks or cisterns fitted with "heads" from which a number of bags of specially woven cloth are suspended in a suitable manner, and into which the melted sugar or liquor to be filtered flows from the melting pans. The bags, though 60 in. or more in circumference, are folded up in such a way that a sheath about 15 in. in circumference can be passed over them. Thus a maximum of filtering surface with a minimum of liquor in each bag is obtained, and a far greater number of bags are got into a given area that would otherwise be possible, while the danger of bursting the bags by leaving them unsupported is avoided. As the liquor goes on filtering through the bags they gradually get filled up with slime and sludge, and the clear liquor ceases to run. Steam is then turned on to the outside of the bags and sheaths, and hot water is run through them to wash out all the sweets they contain. Large doors at the side of the cistern are then opened, and as soon as the bags are cool enough they are removed at the expense of very exacting labour and considerable time, and fresh bags and sheaths are fixed in their places ready for filtering fresh liquor. The dirty bags and sheaths are then washed, mangled and dried, and made ready for use again. In a refinery in Nova Scotia a system has been introduced by which a travelling crane above the bag filters lifts up any head bodily with all its bags attached, and runs it to the mud and washing tanks at the end of the battery, while another similar crane drops another head, fitted with fresh bags, into the place of the one just removed. The whole operation of thus changing a filter occupies about ten minutes, and there is no need for anyone to enter the hot cistern to detach the bags, which are removed in the open air above the mud tank. By this arrangement the work of a refinery can be carried on with about one-half the cisterns otherwise required, because, although it does not reduce the number of bags required per day for a given amount of work, it enables the refiner to use one cistern twice a day with fresh bags, instead of only once as heretofore. In some refineries the travelling cranes are now run by electricity, which still further facilitates the work. Another method of enabling more work to be done in a given time in a given cistern is the use of a bag twice the ordinary length, open at both ends. This, being folded and placed in its sheath, is attached by both ends to the head, so that the melted liquor runs into both openings at the same time. The mud collects at the bottom of the U, and allows the upper part of the bag to filter for a longer time than would be the case if the bottom end were closed and if the bag hung straight like the letter I.

The clear, bright syrup coming from the bag filters passes to the charcoal cisterns or filters. These are large cylindrical vessels from 20 to 50 ft. high, and of such diameter as to hold a given quantity of animal charcoal (also called "bone-black" and "char") in proportion to the contemplated output of the refinery. A very usual size of cistern forming a convenient unit is one that will hold 20 tons of char. Each cistern is fitted with a perforated false bottom, on which a blanket or specially woven cloth is placed, to receive the char which is poured in from the top, and packed as evenly as possible until the cistern is filled. The char is then "settled" by water being slowly run on to it, in order to prevent the syrup making channels for itself and not permeating the whole mass evenly. The cistern being thus packed and settled is closed, and the syrup from the bag filters, heated up to nearly boiling point, is admitted at the top until the cistern is quite full. A small pipe entering below the false bottom allows the air in the cistern to escape as it is displaced by the water or syrup. In some refineries this pipe, which is carried up to a higher level than the top of the cistern, is fitted with a whistle which sounds as long as the air escapes. When the sound ceases the cistern is known to be full, and the entrance of further water or syrup is stopped. The syrup in the cistern is allowed to remain for about twelve hours, by which time the char will have absorbed all the colouring matter in it, as well as the lime. A cistern well packed with 20 tons of char will hold, in addition, about 10 tons of syrup, and after settling, this can be pressed out by allowing second quality syrup, also heated to nearly boiling point, to enter the cistern slowly from the top, or it may be pressed out by boiling water. By carefully watching the flow from the discharge cock of the cistern the change from the first liquor to the next is easily detected, and the discharge is diverted from the canal for the first liquor to the canal for the second liquor, and, when required, to the canals for the third and fourth liquors. Finally, boiling water is admitted and forces out all the last liquor, and then continues to run and wash out the sweets until only a trace remains. This weak solution, called "sweet water," is sometimes used for melting the raw sugar, or it is evaporated in a multiple-effect apparatus to 27° Beaumé density, passed through the char filter, and cooked in the vacuum pan like the other liquors. After the sweets have come away, cold water is passed through the char until no trace of lime or sulphate of lime is found in it; then a large manhole at the bottom of the cistern is opened, and the washed and spent char is removed. In most modern refineries the cisterns are so arranged that the spent char falls on to a travelling band and is conducted to an elevator which carries it up to the drying floor of the charcoal kiln.

Retorts for Reburning Char.—The kilns are made with either fixed or revolving retorts. The former perhaps produce a little better char, but the latter, working almost automatically, require less labour and attention for an equal amount of work, and on the whole have proved very satisfactory. From the drying floor on which the spent char is heaped up it falls by gravitation into the retorts. These are set in a kiln or oven, and are kept at as even a temperature as possible, corresponding to a dull cherry-red. Below each retort, and attached to it, is a cooler formed of thin sheet-iron, which receives the hot char as it passes from the retort, and at the bottom of the cooler is an arrangement of valves which permits a certain amount of char to drop out and no more. With the fixed retorts these valves are worked from time to time by the attendant, but with revolving retorts they are worked continuously and automatically and allow from sixteen to twenty-four ounces of char to escape per minute from each cooler, and so make room in the retort above for a corresponding quantity to enter from the drying floor. The reburnt and cooled char is collected and sent back to the char cisterns. In the best-appointed refineries the whole of the work in connexion with the char is performed mechanically, with the exception of packing the filter cisterns with fresh char and emptying the spent and washed char on to the carrying bands. In former days, when refining sugar or "sugar baking" was supposed to be a mystery only understood by a few of the initiated, there was a place in the refinery called the "secret room," and this name is still used in some refineries, where, however, it applies not to any room, but to a small copper cistern, constructed with five or six or more divisions or small canals, into which all the charcoal cisterns discharge their liquors by pipes led up from them to the top of the cistern. Each pipe is fitted with a cock and swivel, in such a manner that the liquor from the cistern can be turned into the proper division according to its quality.

Vacuum Pans and Receivers.—The filtered liquors, being collected in the various service tanks according to their qualities, are drawn up into the vacuum pans and boiled to crystals. These are then discharged into large receivers, which are generally fitted with stirrers, and from the receivers the cooked mass passes to the centrifugal machines. As in the beetroot factories, these machines work on different systems, but nearly all are arranged to turn out sugar in lumps or tablets presenting an appearance similar to that of loaf sugar made in moulds, as this kind of sugar meets with the greatest demand. Granulated sugar, so called, is made by passing the crystals, after leaving the centrifugals, through a large and slightly inclined revolving cylinder with a smaller one inside heated by steam. The sugar fed into the upper end of the cylinder gradually works its way down to the lower, showering itself upon the heated central cylinder. A fan blast enters the lower end, and, passing out at the upper end, carries off the vapour produced by the drying of the sugar, and at the same time assists the evaporation. The dry sugar then passes into a rotating screen fitted with two meshes, so that three grades of sugar are obtained, the coarsest being that which falls out at the lower end of the revolving screen.

Recent Improvements.—Systematic feeding for the vacuum pan and systematic washing of the massecuite have been recently introduced not only into refineries, but also into sugar houses or factories on plantations of both cane and beetroot, and great advantages have resulted from their employment. The first-mentioned process consists of charging and feeding the vacuum pan with the richest syrup, and then as the crystals form and this syrup becomes thereby less rich the pan is fed with syrup of lower richness, but still of a richness equal to that of the mother-liquor to which it is added, and so on until but little mother-liquor is left, and that of the poorest quality. The systematic washing of the massecuite is the reverse of this process. When the massecuite, well pugged and prepared for purging, is in the centrifugals, it is first washed with syrup of low density, to assist the separation of mother-liquor of similar quality, this washing being supplemented by the injection of pure syrup of high density, or "clairce," when very white sugar is required. The manufacturers who have adopted this system assert that, as compared with other methods, not only do they obtain an increased yield of sugar of better quality, but that they do so at a less cost for running their machines and with a reduced expenditure in sugar and "clairce." "Clairce" is the French term for syrup of 27° to 30° Beaumé specially prepared from the purest sugar.

Apart from modifications in the details of sugar refining which have come into use in late years, it should be mentioned that loaf sugar made in conical moulds, and sugars made otherwise, to resemble loaf sugar, have practically disappeared from the trade, having been replaced by cube sugar, which is found to be more economical as subject to less waste by grocers and housekeepers, and also less troublesome to buy and sell. Its manufacture was introduced into England many years ago by Messrs Henry Tate & Sons, and they subsequently adopted and use now the improved process and apparatus patented in March 1890 by M Gustave Adant, a foreman sugar refiner of Brussels.

The following is a brief description of the process and apparatus, as communicated by the courtesy of Messrs Henry Tate & Sons, Ltd.: Groups of cells or moulds are built within and against a cylindrical iron casing, by means of vertical plates inserted in grooves and set radially to the axis of the casing. Each cell is of suitable dimensions to turn out a slab of sugar about 14 in. long—this being about the height of the cell—and about 8 in. wide and about ½ in. to ⅝ in. thick. By means of a travelling crane the casing is placed within an iron drum, to which it is secured, and is then brought under an overhead vacuum pan, from which the cells are filled with massecuite. After cooling, the casing is lifted out of the drum by a crane, assisted by compressed air, and is then conveyed by a travelling crane to a vertical centrifugal, inside of which it is made fast. Suitable provision is made for the egress of syrup from the massecuite in the cells when undergoing purging in the centrifugal; and the washing of the crystals can be aided by the injection of refined syrup and completed by that of "clairce." When this is done, the casing is hoisted out of the centrifugal and the vertical plates and the slabs of sugar are extracted. The slabs are sent by a conveyor to a drying stove, whence they issue to pass through a cutting machine, provided with knives so arranged that the cutting takes place both downwards and upwards, and here the slabs are cut into cubes. The cubes fall from the cutting machine on to a riddling machine, which separates those which are defective in size from the rest. These latter pass to automatic weighing machines, which drop them, in quantities of 1 cwt., into wooden boxes of uniform measurement, made to contain that weight; and the boxes are then conveyed to the storehouse, ready for sale.

History and Statistics.—Strabo xv. i. 20, has an inaccurate notice from Nearchus of the Indian honey-bearing reed, and various classical writers of the first century of our era notice the sweet sap of the Indian reed or even the granulated salt-like product which was imported from India, or from Arabia and Opone (these being entrepôts of Indian trade),[1] under the name of saccharum or σάκχαρι (from Skr. *sarkara*, gravel, sugar), and used in medicine. The art of boiling sugar was known in Gangetic India, from which it was carried to China in the first half of the 7th century; but sugar refining cannot have then been known, for the Chinese learned the use of ashes for this purpose only in the Mongol period, from Egyptian visitors.[2] The cultivation of the cane in the West spread from Khūzistān in Persia. At Gundē-Shāpūr in this region "sugar was prepared with art" about the time of the Arab conquest,[3] and manufacture on a large scale was carried on at Shuster, Sūs and Askar-Mokram throughout the middle ages.[4] It has been plausibly conjectured that the art of sugar refining, which the farther East learned from the Arabs, was developed by the famous physicians of this region, in whose pharmacopoeia sugar had an important place. Under the Arabs the growth and manufacture of the cane spread far and wide, from India to Sūs in Morocco (Edrīsī, ed. Dozy, p. 62), and were also introduced into Sicily and Andalusia.

In the age of discovery the Portuguese and Spaniards became the great disseminators of the cultivation of sugar; the cane was planted in Madeira in 1420; it was carried to San Domingo in 1494; and it spread over the occupied portions of the West Indies and South America early in the 16th century. Within the first twenty years of the 16th century the sugar trade of San Domingo expanded with great rapidity, and it was from the dues levied on the imports brought thence to Spain that Charles V. obtained funds for his palace-building at Madrid and Toledo. In the middle ages Venice was the great European centre of the sugar trade, and towards the end of the 15th century a Venetian citizen received a reward of 100,000 crowns for the invention of the art of making loaf sugar. One of the earliest references to sugar in Great Britain is that of 100,000 ℔ of sugar being shipped to London in 1319 by Tomasso Loredano, merchant of Venice, to be exchanged for wool. In the same year there appears in the accounts of the chamberlain of Scotland a payment at the rate of 1s. 9½d. per ℔ for sugar. Throughout Europe it continued to be a costly luxury and article of medicine only, till the increasing use of tea and coffee in the 18th century brought it into the list of principal food staples. The increase in the consumption is exemplified by the fact that, while in 1700 the amount used in Great Britain was 10,000 tons, in 1800 it had risen to 150,000 tons, and in 1885 the total quantity used was almost 1,100,000 tons.

In 1747 Andreas Sigismund Marggraf, director of the physical classes in the Academy of Sciences, Berlin, discovered the existence of common sugar in beetroot and in numerous other fleshy roots which grow in temperate regions. But no practical use was made of the discovery during his lifetime. The first to establish a beet-sugar factory was his pupil and successor, Franz Carl Achard, at Cunern (near Breslau) in Silesia in 1801. The processes used were at first very imperfect, but the extraordinary increase in the price of sugar on the Continent caused by the Napoleonic policy gave an impetus to the industry, and beetroot factories were established at many centres both in Germany and in France. In Germany the enterprise came to an end almost entirely with the downfall of Napoleon I.; but in France, where at first more scientific and economical methods of working were introduced, the manufacturers were able to keep the industry alive. It was not, however, till after 1830 that it secured a firm footing; but from 1840 onwards it advanced with giant strides.

Under the bounty system, by which the protectionist countries of Europe stimulated the beet sugar industry by bounties on exports, the production of sugar in bounty-paying countries was encouraged and pushed far beyond the limits it could have reached without state aid. At the same time the consumption of sugar was greatly restricted owing to the heavy excise duties imposed mainly to provide for the payment of the bounties. The very large quantity of output made available for export under these exceptional conditions brought about the flooding of the British and other markets with sugars at depressed prices, not unfrequently below the prime cost of production, to the harassment of important industries carried on by British refiners and sugar-growing colonies. In these circumstances, the British government sent out invitations on the 2nd of July 1887 for an international conference to meet in London. The conference met, and on the 30th of August 1888 a convention was signed by all the powers represented except France—namely, by Austria, Belgium, Germany, Great Britain, Italy, the Netherlands, Russia and Spain. France withdrew because the United States was not a party to it. The first article declared that "The high contracting parties engage to take such measures as shall constitute an absolute and complete guarantee that no open or disguised bounty shall be granted on the manufacture or exportation of sugar." The seventh article provided that bountied sugars (*sucres primés*) must be excluded from import into the territories of the signatory powers, by absolute prohibition of entry or by levying thereon a special duty in excess of the amount of the bounties, from which duty sugars coming from the contracting countries, and not bounty-fed, must be free. The convention was to be ratified on the 1st of August 1890, and was to be put in force on the 1st of September 1891.

The convention of 1888 was never ratified, and it is doubtful whether its ratification was urged, for a bill introduced by the British government in 1889 to give it effect was not pressed, and it was manifest that there was hesitation—which presently became refusal—to uphold the policy of the penalties on the importation of bountied sugar imposed by the seventh article, without which the convention would be so much waste paper.

Eight years later, on the 1st of August 1896, the bounties offered by the governments of Germany and Austria-Hungary were approximately doubled, and France had a bill in preparation to increase hers correspondingly, although it was computed that they were even then equivalent to a grant of £3, 5s. per ton. So wrote Mr Chamberlain, the colonial secretary, on the 9th of November following, to the treasury. The minute plainly stated that it had become a question whether the continued enjoyment of advantages resulting from the importation of cheap bounty-fed sugar to some British industries did not involve the ruin of the British sugar-producing colonies; and that he was not prepared, as secretary of state for the colonies, to accept the responsibility of allowing matters to take their course and to acquiesce in the policy of non-intervention hitherto pursued in regard to the bounties without having satisfied himself as to what such a policy might entail as regarded both the colonies and the exchequer. Mr Chamberlain concluded by asking whether the treasury would consent to sending a royal commission to the West Indies to inquire into the effect of the foreign sugar bounties on their principal industry.

The treasury accepted the proposal, and a royal commission proceeded to the West Indies in December 1896, and reported a few months later in 1897. Only one commissioner, however, denounced the bounties as the real cause of the utter breakdown of trade and of the grievous distress which all three had witnessed

[1] Lucan iii. 237; Seneca, *Epist.* 84; Pliny, *H.N.* xii. 8 (who supposes that sugar was produced in Arabia as well as in India); *Peripl. mar. Eryth.* § 14; Dioscorides ii. 104. The view, often repeated, that the saccharum of the ancients is the hydrate of silica, sometimes found in bamboos and known in Arabian medicine as *tabāshīr*, is refuted by Yule, *Anglo-Indian Glossary*, p. 654; see also *Not. et extr. des MSS. de la bibl. nat.* xxv. 267 seq.

[2] Marco Polo, ed. Yule, ii. 208, 212. In the middle ages the best sugar came from Egypt (Kazwīnī i. 262), and in India coarse sugar is still called Chinese and fine sugar Cairene or Egyptian.

[3] So the Armenian *Geography* ascribed to Moses of Chorene (*q.v.* for the date of the work); St Martin, *Mém. sur l'Arménie*, ii. 372.

[4] Iṣṭakhrī p. 91; Yākūt ii. 497. Tha'ālibī, a writer of the 11th century, says that Askar-Mokram had no equal for the quality and quantity of its sugar, "notwithstanding the great production of 'Irāk, Jorjān and India." It used to pay 50,000 ℔ of sugar to the sultan in annual tribute (*Laṭāif*, p. 107). The names of sugar in modern European languages are derived through the Arabic from the Persian *shakar*.

and fully acknowledged. But the minute and commission were not barren of result. A fresh conference of the powers assembled at Brussels, on the invitation of the Belgian government, on the 7th of June 1898; and although the British delegates were not empowered to consent to a penal clause imposing countervailing duties on bountied sugar, the Belgian premier, who presided, was able to assure them that if Great Britain would agree to such a clause, he could guarantee the accession of the governments of Germany, Austria, Holland and his own. Of all the countries represented—Germany, Austria-Hungary, Belgium, Spain, France, Great Britain, the Netherlands, Russia and Sweden—only one, namely France, was opposed to the complete suppression of all export bounties, direct or indirect; and Russia declined to discuss the question of her internal legislation, contending that her system did not amount to a bounty on exportation.

Apart from the proceedings at the sittings, much of the actual work of the conference was done by informal discussion, undertaken to discover some means of arriving at a common understanding. Was a compromise possible which would bring about a satisfactory settlement? The British delegates wrote that it appeared that there were at that time but two methods of securing the suppression of the bounty system—an arrangement for limitation of the French and Russian bounties acceptable to the other sugar-producing states, in return for the total abolition of their bounties; or, a convention between a certain number of these states, providing for the total suppression of their bounties, and for the prohibition of entry into their territory of bounty-fed sugars, or countervailing duties prohibiting importation.

The Belgian government thought a compromise might be possible. A proposal was annexed to the *procès-verbal* of the final sitting, and the president closed the first session of the conference on the 25th of June 1898 with the expression of a hope that the delegates would soon reassemble.

The annual aggregate output of cane and date sugar in India was short of 4,000,000 tons. Exportation had long ceased, partly owing to the bountied competition of beet sugar, and partly because the people had become able to afford the consumption of a greater quantity than they produced; and German and Austrian sugars were pouring into the country to supply the deficiency. But the importation of foreign sugar, cheapened by foreign state aid to a price which materially reduced the fair and reasonable profit of native cultivators, was a state of things the Indian government could not accept. On the 20th of March 1899 an act, authorizing the imposition of countervailing duties on bounty-fed articles at the port of importation, was passed by the Council of India, and received the assent of the governor-general.

This decisive step was not long in making itself felt in the chanceries of Europe. In October 1900 a conditional agreement for the reduction of the bounties was made in Paris between France, Germany and Austria-Hungary; in February 1901 the Belgian government proposed a new session of the Conference of 1898, and on the 16th of December following Brussels welcomed once more the delegates of all the powers, with the exception of Russia, to the eighth European Sugar Bounty Conference since that of Paris in 1862. The discussion lasted over eight sittings, but the conference, to which the British delegates had come with powers to assent to a penal clause, arrived at an understanding, and a convention was signed in March 1902. This was ratified on the 1st of February 1903, subject to a declaration by Great Britain that she did not consent to penalize bounty-fed sugar from the British colonies.

It was agreed "to suppress the direct and indirect bounties which might benefit the production or export of sugar, and not to establish bounties of this kind during the whole duration of the convention," which was to come into force on the 1st of September 1903, and to remain in force five years, and thenceforward from year to year, in case no state denounced it twelve months before the 1st of September in any year. A permanent commission was established to watch its execution.

The full text in French, with an English translation, of the Sugar Convention, signed at Brussels on the 5th of March 1902 by the plenipotentiaries of the governments of Germany, Austria-Hungary, Belgium, Spain, France, Great Britain, Italy, the Netherlands and Sweden, will be found in a return presented to parliament in April 1902 (Miscellaneous, No. 5, 1902, Cd. 1013).

Sir H. Bergne reported on the 27th of July 1907 to Sir Edward Grey that—

"The permanent session had met in special session on the 25th of July, to consider the suggestion of His Britannic Majesty's government to the effect that, if Great Britain could be relieved from the obligation to enforce the penal provisions of the convention, they would be prepared not to give notice on the 1st of September next of their intention to withdraw on the 1st of September 1908 a notice which they would otherwise feel bound to give at the appointed time"; and he added that "At this meeting, a very general desire was expressed that, in these circumstances, arrangements should, if possible, be made which would permit Great Britain to remain a party to the Sugar Convention."

On the 1st of August 1907 the Belgian minister in London transmitted to Sir Edward Grey a draft additional act prepared by the commission for carrying out the proposal of His Britannic Majesty's government, and on the 28th of August following an additional act was signed at Brussels by the plenipotentiaries of the contracting parties, by which they undertook to maintain the convention of the 5th of March 1902 in force for a fresh period of five years.

On the 2nd of December 1907 Sir H. Bergne wrote to the foreign office from Brussels, reporting that a special session of the permanent commission, established under the sugar bounties convention, had opened on the 18th of November, and the principal matter for its consideration had been the application of Russia to become a party to the convention on special terms. A protocol admitting Russia to the sugar convention was signed at Brussels on the 19th of December 1907.

Sir A. H. Hardinge on behalf of Great Britain made the following declaration:—

"The assent of His Majesty's government to the present protocol is limited to the provisions enabling Russia to adhere to the convention, and does not imply assent to the stipulation tending to restrict the importation of Russian sugar."

When, in April 1908, Mr Asquith became premier, and Mr Lloyd George chancellor of the exchequer, the sugar convention

TABLE II.

The world's trade in cane and beet sugar in tons avoirdupois at decennial periods from 1840 to 1870, inclusive, and yearly from 1871 to 1901 inclusive, with the percentage of beet sugar and the average price per cwt. in shillings and pence. Tons avoirdupois of 2240 ℔ = 1016 kilogrammes.

The quantities of cane sugar are based on the trade circulars of Messrs Willett & Gray of New York; those of beet sugar on the trade circulars of Messrs F. O. Licht of Magdeburg; and the prices are obtained from statements supplied by importers into the United States of the cost in foreign countries of the sugars which they import. The table has been adapted from the Monthly Summary of Commerce and Finance of the United States, January 1902, prepared in the Bureau of Statistics, Treasury Department, Washington Government Printing Office, 1902.

TABLE III.

Quantities of raw and refined cane and beet sugar in tons avoirdupois imported into the United Kingdom in 1870 and in 1875, and yearly from 1880 to 1901 inclusive, with the consumption per head of the population in ℔ and the price per cwt. of raw and refined sugar.

Year.	Raw Cane.	Raw Beet.	Refined Cane.	Refined Beet.	Total.	Consumption per head.		Total.	Price per cwt.

of 1902 had thus been renewed in a modified form. Great Britain, instead of agreeing to prohibit the importation of bounty-fed sugar, was allowed to permit it under certain limits. Russia, which gave bounties, was to be allowed to send into European markets not more than 1,000,000 tons within the next five years, and Great Britain undertook to give certificates guaranteeing that sugar refined in the United Kingdom and exported had not been bounty-fed. The renewal of the convention was disapproved by certain Liberal politicians, who insisted that the price of sugar had been raised by the convention; and Sir Edward Grey said that the government had intended to denounce the convention, but other countries had urged that Great Britain had induced them to enter into it, and to alter their fiscal system for that purpose, and it would be unfair to upset the arrangement. Besides, denunciation would not have meant a return to prior conditions; for other countries would have continued the convention, and probably with success, and would have proposed prohibitive or retaliatory duties in respect of British sugar, with bad results politically. Still the British government had been prepared to denounce the convention in view of the penal clause which had ensured the exclusion of bounty-fed sugar, either directly or through the imposition of an extra duty. But this had been removed, and it was now unreasonable to insist on denunciation. Russia would have made the same arrangement she had obtained had we seceded from the convention. She had formerly sent to England about 40,000 tons of sugar yearly; she might now send 200,000 tons. Was this limitation a reason for sacrificing the advantages we had gained? Under the original terms of the convention Great Britain might have been asked to close her ports to sugar proceeding from one country or another. This was now impossible.

TABLE IV.

The cane and beet sugar crops of the world for 1909–1910, with the average of the crops for the seven preceding years from 1902–1903, in tons of 2240 lb.

A.—Cane sugar (compiled from the *Weekly Statistical Sugar Trade Journal* of Messrs Willett & Gray of New York, and books and reports published under the authority of the government of India).

The matter temporarily dropped, but certain Liberal members of parliament continued to press for the withdrawal of Great Britain from the convention, it being stated that a promise had been privately given by Sir Henry Campbell-Bannerman that the government would withdraw as soon as practicable. On the 15th of July 1908, Mr Asquith said that Sir Edward Grey had announced in the House of Commons on the 6th of June 1907 that the British government intended to negotiate with the powers for the renewal of the convention, on condition that they would relinquish the penal clause, and that none of the obligations in the convention as renewed were penal or required statutory authority.

Tables II., III. (p. 773) and IV. (p. 774) give statistics of cane and beet sugar production.

The quantities for India have been computed from information furnished by the India office, and publications made under authority of the secretary of state and the commercial intelligence department of the Indian government.

The whole of the sugar produced in India is consumed in the country and sugar is imported, the bulk of it being cane sugar coming from Mauritius and Java, and about 85% of the import is of high quality resembling refined sugar.

It would appear that the purchasing power of the inhabitants of India has increased of late years, and there is a growing demand for refined sugar, fostered by the circumstance that modern processes of manufacture can make a quality of sugar, broadly speaking, equal to sugar refined by animal charcoal, without using charcoal, and so the religious objections to the refined sugars of old days have been overcome. (A. Ch.; V. W. Ch.)

SUGAR-BIRD, the English name commonly given in the West India Islands to the various members of the genus *Certhiola* (belonging to the Passerine family Coerebidae[1]) for their habit of frequenting the curing-houses where sugar is kept, apparently attracted thither by the swarms of flies. They often come into dwelling-houses, hopping from one piece of furniture to another and carefully exploring the surrounding objects with intent to find a spider or insect. In their figure and motions they remind a northern naturalist of a nuthatch, while their coloration—black, yellow, olive, grey and white—recalls to him a titmouse. They generally keep in pairs and build a domed but untidy nest, laying therein three eggs, white, blotched with rusty-red. Many species are recognized, some of them with a very limited range; three are continental, with a joint range extending from southern Mexico to Peru, Bolivia and south-eastern Brazil, while others are peculiar to certain of the Antilles, and several of them to one island only. Thus *C. caboti* is limited, so far as is known, to Cozumel (off Yucatan), *C. tricolor* to Old Providence, *C. flaveola* (the type of the genus) to Jamaica, and so on, while islands that are in sight of one another are often inhabited by different "species." The genus furnishes an excellent example of the effects of isolation in breaking up an original form, while there is comparatively little differentiation among the individuals which inhabit a large and continuous area. The non-appearance of this genus in Cuba is very remarkable. (A. N.)

SUGER (*c.* 1081–1151), French ecclesiastic, statesman and historian, was born of poor parents either in Flanders, at St Denis near Paris or at Toury in Beauce. About 1091 he entered the abbey of St Denis. Until about 1104 he was educated at the priory of St Denis de l'Estrée, and there first met his pupil King Louis VI. From 1104 to 1106 Suger attended another school, perhaps that attached to the abbey of St Benoît-sur-Loire. In 1106 he became secretary to the abbot of St Denis. In the following year he was made provost of Berneval in Normandy, and in 1109 of Toury. In 1118 he was sent by Louis VI. to the court of Pope Gelasius II. at Maguelonne, and lived from 1121 to 1122 at the court of his successor, Calixtus II. On his return from Italy Suger was appointed abbot of St Denis. Until 1127 he occupied himself at court mainly with the temporal affairs of the kingdom, while during the following decade he devoted himself to the reorganization and reform of St Denis. In 1137 he accompanied the future king, Louis VII., into Aquitaine on the occasion of that prince's marriage to Eleanor of Aquitaine, and during the second crusade was one of the regents of the kingdom (1147–1149). He was bitterly opposed to the king's divorce, having himself advised the marriage. Although he disapproved of the second crusade, he himself, at the time of his death, on the 31st of January 1151, was preaching a new crusade.

Suger was the friend and counsellor both of Louis VI. and Louis VII. He urged the king to destroy the feudal bandits, was responsible for the royal tactics in dealing with the communal movements, and endeavoured to regularize the administration of justice. He left his abbey, which possessed considerable property, enriched and embellished by the construction of a new church built in the nascent Gothic style.

Suger was the foremost historian of his time. He was the author of a panegyric on Louis VI. (*Vita Ludovici regis*), and part-author of the perhaps more impartial history of Louis VII. (*Historia gloriosi regis Ludovici*). In his *Liber de rebus in administratione sua gestis*, and its supplement *Libellus de consecratione ecclesiae S. Dionysii*, he treats of the improvements he had made to St Denis, describes the treasure of the church, and gives an account of the rebuilding. Suger's works served to imbue the monks of St Denis with a taste for history, and called forth a long series of quasi-official chronicles.

See O. Cartellieri, *Abt Suger von Saint-Denis* (Berlin, 1898); A. Luchaire, *Louis le Gros* (Paris, 1890); F. A. Gervaise, *Histoire de Suger* (Paris, 1721).

SUGGESTION. By the older British writers on psychology the words "suggest" and "suggestion" were used in senses very close to those which they have in common speech; one idea was said to suggest another when it recalled that other to mind or (in the modern phrase) reproduced it. Modern studies in mental pathology and hypnotism (*q.v.*) have led to the use of these words by psychologists in a special and technical sense. The hypnotists of the Nancy school rediscovered and gave general currency to the doctrine that the most essential feature of the hypnotic state is the unquestioning obedience and docility with which the hypnotized subject accepts, believes, and acts in accordance with every command or proposition of the hypnotizer. Commands or propositions made to the subject (they may be merely implied by a gesture, a glance, or a chance remark to a third person) and accepted with this peculiarly uncritical and intense belief were called "suggestions"; and the subject that accepted them in this fashion was said to be "suggestible." It has also been made abundantly clear, chiefly by the labours of French physicians, that a high degree of "suggestibility" is a leading feature of hysteria, and that this fact is the key to the understanding of very many of its protean manifestations.

It is also becoming widely recognized that the suggestibility of hypnosis and of hysteria is conditioned by a peculiar state of the brain, namely a cerebral or mental dissociation, which in hypnosis is temporarily induced by the operations of the hypnotist, and in hysteria arises from some deficiency of energy in the whole psycho-physical system. In respect to these points there is now a wide consensus of opinion among the leading authorities; but as to the range and scope of suggestion in our mental life great differences of opinion still obtain. We may distinguish three principal views. Firstly, it is maintained by a number of physicians (notably by Professor Pierre Janet, whose profound studies of hysterical patients are justly celebrated) that all hypnotizable persons are hysterical and that suggestibility is a condition peculiar to hysterical subjects. In view of the assertions in recent years of several physicians of high repute to the effect that they find more than 90% of all subjects hypnotizable, it would seem that this view cannot be maintained, and that this restriction of suggestion to hysterical subjects only, and the stigmatization of suggestibility as in every case a morbid symptom, are errors arising from too exclusive occupation with its manifestations in this field. A second group consists of writers who admit that suggestion may operate in normal minds, but who, while recognizing that it is not an essentially pathological process, maintain that it is a process of very peculiar and exceptional nature that has little or no affinity with normal mental operations. They hold that suggestion, whether it occurs in morbid or in healthy subjects, always implies the coming into operation of some obscurely conceived faculty or region of the mind which is present in all men, but which usually lies hidden or submerged beneath the flow of our more commonplace mental activities. This submerged faculty or system of faculties, which is held by these authors to be operative in all processes of suggestion, is variously designated by them the secondary or submerged stratum of consciousness, the subconscious or subliminal self (see Subliminal Self). The writers of this group insist upon the more startling of the effects producible by suggestion, the more profound changes of bodily and mental processes, such as paralysis,

[1] Known in French as *Guitguits*, a name used for them also by some English writers. The *Guitguit* of Hernandez (*Rer. medic. N. hisp. thesaurus*, p. 56), a name said by him to be of native origin, can hardly be determined, though thought by Montbeillard (*Hist. nat. oiseaux*, v. 529) to be what is now known as *Coereba caerulea*, but that of later writers is *C. cyanea*. The name is probably onomatopoetic, and very likely analogous to the "quit" applied in Jamaica to several small birds.

contracture, hyperaesthesia, increased power of recollection, hallucinations (*q.v.*), &c.; and they regard dissociation as the process by which the submerged and supernormal faculty (or faculties) that they postulate is liberated from the dominance of the normal waking self.

A third view has been rapidly gaining ground and is now predominant. It connects itself with, and bases itself upon, the view of Professor Bernheim and his colleagues of the Nancy school of hypnotism. According to this view all men are normally suggestible under favourable conditions, and the hypnotic subject and the hysteric patient differ from the normal human being chiefly in that their normal suggestibility is more or less (sometimes very greatly) increased, owing to the prevalence of the state of cerebral dissociation.

According to this third view, suggestion may be defined as the communication of any proposition from one person (or persons) to another in such a way as to secure its acceptance with conviction, in the absence of adequate logical grounds for its acceptance. The idea or belief so introduced to the mind of the recipient is held to operate powerfully upon his bodily and mental processes in proportion to the degree of its dominance over all other ideas or mental processes; and the extraordinary character of the effects, both bodily and mental, of suggestion in hypnotic and hysterical subjects is held to be due to the fact that, in these conditions of mental dissociation, the dominance of the suggested idea is complete and absolute; whereas in the absence of such dissociation the operation of the suggested idea is always subject to some weakening or inhibition through the influence of many opposed or incompatible tendencies and ideas, even if these do not rise into explicit consciousness.

This third view seems justified by the facts that no sharp line can be drawn between the suggestibility of normal men and that of hypnotized or hysterical subjects, and that under favourable conditions many of the most striking results of suggestion (*e.g.* hallucinations, contractures, inability to move, insensibility of various sense-organs, and so forth) may be produced in subjects who present at the time no other symptom of the hypnotic or hysterical condition.

If, then, we recognize, as we must, that the alogical production of conviction is the essence of suggestion, and that this frequently occurs in normal minds as well as in those suffering from various degrees of dissociation, it becomes necessary to define the conditions that favour the operation of suggestion in normal minds.

These conditions are resident, on the one hand, in the recipient of the suggestion, and, on the other hand, in the source from which the suggestion comes. Of the conditions of the former class three seem to be of principal importance.

(*a*) Defect of knowledge: the defect may be quantitative or qualitative, *i.e.* it may consist in the lack of knowledge or of firmly established beliefs about the subject of the proposition, or it may consist in the lack of systematic organization of such knowledge as the mind possesses. The well-trained mind is relatively insuggestible, firstly because it possesses large stores of knowledge and belief; secondly, because this mass of knowledge and belief is systematically organized in such a way that all its parts hang together and mutually support one another. On the other hand, the young child, the uncultured adult, and especially the savage, are apt to be suggestible in regard to very many topics, first, because they have relatively little knowledge; secondly, because what little they have is of a low degree of organization; *i.e.* it does not form a logically coherent system whose parts reciprocally support one another. Suggestion in such cases may be said to be conditioned by primitive credulity or the suggestibility of ignorance. (*b*) But the same person will not be found to be equally suggestible at all times under similar external conditions. There are changes of mental state which, without overstepping the limits of the normal, condition varying degrees of increased suggestibility. A man is least suggestible when his mind works most efficiently, when he is most vigorous and most wide awake; every departure from this state, due to fatigue, bodily ill-health, emotional perturbation, drugs or any other cause, favours suggestibility. (c) Persons of equal degrees of knowledge or ignorance will be found, even at their times of greatest mental efficiency, to be unequally suggestible owing to differences of native disposition; one person is by nature more open than another to personal influence, more easily swayed by others, more ready to accept their dicta and adopt their opinions for his own. Differences of this kind are probably the expression of differences in the native strength of one of the fundamental instinctive dispositions of the human mind, an instinct which is called into play by the presence of persons of superior powers and the excitement of which throws the subject into an attitude of submission or subjection towards the impressive personality.

Considered from the side of the agent, suggestion is favoured by whatever tends to render him impressive to the subject or patient—great bodily strength or stature, fine clothes, a confident manner, superior abilities of any kind, age and experience, any reputation for special capacities, high social position or the occupation of any position of acknowledged authority; in short, all that is summed up by the term "personality," all that contributes to make a personality "magnetic" or to give it prestige renders it capable of evoking on the part of others the submissive suggestible attitude. A group of persons in agreement is capable of evoking the suggestible attitude far more effectively than any single member of the group, and the larger the group the more strongly does it exert this influence. Hence the suggestive force of the popularly accepted maxims and well-established social conventions; such propositions are collective suggestions which carry with them all the immense collective prestige of organized society, both of the present and the past; they embody the wisdom of the ages. It is in the main through the suggestive power of moral maxims, endowed with all the prestige of great moral teachers and of the collective voice of society, that the child is led to accept with but little questioning the code of morals of his age and country; and the propagation of all religious and other dogma rests on the same basis. The normal suggestibility of the child is thus a principal condition of its docility, and it is in the main by the operation of normal suggestion that society moulds the characters, sentiments, and beliefs of its members, and renders the mass of its elements harmonious and homogeneous to the degree that is a necessary condition of its collective mental life. Normal suggestion produces its most striking effects in the form of mass-suggestion, *i.e.* when it operates in large assemblies or crowds, especially if the members have but little positive knowledge and culture. For, when a belief is propagated by collective suggestion through the large mass of men, each falls under the suggestive sway of the whole mass; and under these conditions the operation of suggestion is further aided by the universal tendency of mankind to imitation and sympathy, the tendency to imitate the actions of, and to experience the emotions expressed by, those about one.

Conditions very favourable to mass-suggestion prevailed during the middle ages of European history; for these "dark ages" were characterized by the existence of dense populations, among whom there was free intercourse but very little positive knowledge of nature, and who were dominated by a church wielding immense prestige. Hence the frequent and powerful operations of suggestion on a large scale. From time to time fantastic beliefs, giving rise to most extravagant behaviour, swept over large areas of Europe like virulent epidemics—epidemics of dancing, of flagellation, of hallucination, of belief in the miraculous powers of relics or of individuals, and so forth. In these epidemics all the conditions favourable to normal suggestion were generally present in the highest degree, with the result that in great numbers of persons there were produced the more extreme effects of suggestion, such as are usually associated with the hysterical or hypnotic state. At the present time similar manifestations occur in a modified form, as *e.g.* the popular pilgrimages to Lourdes, Holywell and other places that from time to time acquire reputations for miraculous curative powers.

Auto-suggestion.—Although auto-suggestion does not strictly fall under the definition of suggestion given above, its usage to denote a mental process which produces effects very similar to those producible by suggestion is now so well established that it must be accepted. In auto-suggestion a proposition is formulated in the mind of the subject rather than communicated from another mind, and is accepted with conviction in the absence of adequate logical grounds. Generally the belief is initiated by some external event or some bodily change, or through some interpretation of the behaviour of other persons; *e.g.* a man falls on the road and a wagon very nearly passes over his legs, perhaps grazing them merely; when he is picked up, his legs are found to be paralysed. The event has induced the conviction that his legs are seriously injured, and this conviction operates so effectively as to realize itself. Or a savage, suffering some slight indisposition, interprets the behaviour of some person in a way which leads him to the conviction that this person is compassing his death by means of magical practices; accordingly he lies down in deep despondency and, in the course of some days or weeks, dies, unless his friends succeed in buying off, or in some way counteracting, the malign influence. Or, as a more familiar and trivial instance of auto-suggestion, we may cite the case of a man who, having taken a bread pill in the belief that it contains a strong purgative or emetic, realizes the results that he expects.

SUHL, a town of Germany, in the province of Prussian Saxony, picturesquely situated on the Lauter, on the southern slope of the Thuringian Forest, 6½ m. N.E. of Meiningen and 29 m. S.W. of Erfurt by rail. Pop. (1905), 13,814. The armourers of Suhl are mentioned as early as the 9th century, but they enjoyed their highest vogue from 1550 to 1634. The knights of south Germany especially prized the swords and armour of this town, and many of the weapons used in campaigns against the Turks and in the Seven Years' War are said to have been manufactured at Suhl. It has suffered considerably in modern times from the competition of other towns in this industry, especially since the introduction of the breech-loading rifle. It still contains, however, large factories for firearms military and sporting, and side arms, besides ironworks, machine-works, potteries and tanneries. The once considerable manufacture of fustian has declined. A brine spring (Soolquelle) at the foot of the neighbouring Domberg is said to have given name to the town.

Suhl, which obtained civic rights in 1527, belonged to the principality of Henneberg, and formed part of the possessions of the kingdom of Saxony assigned to Prussia by the Congress of Vienna in 1815.

See Werther, *Chronik der Stadt Suhl* (2 vols., Suhl, 1846–1847).

SUICIDE (from Lat. *sui*, of oneself, and *cidium*, from *caedere*, to kill), the act of intentionally destroying one's own life. The phenomenon of suicide has at all times attracted a large amount of attention from moralists and social investigators. Its existence is looked upon, in Western civilization, as a sign of the presence of maladies in the body politic which, whether remediable or not, deserve careful examination. It is, of course, impossible to compare Western civilization in this respect with, say, Japan, where suicide in certain circumstances is part of a distinct moral creed. In Christian ethics and Christian law it is wrong, indeed illegal, as a *felo de se*, self-murder. It is within comparatively recent years that the study of suicide by means of the vital statistics of various European countries has demonstrated that while the act may be regarded as a purely voluntary one, yet that suicide as a whole conforms there to certain general laws, and is influenced by conditions other than mere individual circumstances or surroundings. Thus it can be shown that each country has a different suicide-rate, and that while the rate for each country may fluctuate from year to year, yet it maintains practically the same relative proportions to the rates of other countries. The following table shows the suicide-rate for various European countries (Bertillon):—

TABLE I.

Country.	Period of Observation.	Annual Number of Suicides per Million Inhabitants.
Saxony	1878–1882	392
Denmark	1880–1882	251
Switzerland	1878–1882	239
Baden	"	198
Württemberg	1877–1881	189
France	1878–1882	180
Prussia	"	166
Belgium	"	100
Sweden	"	92
England and Wales	"	75
Norway	"	69
Scotland	1877–1881	49
Ireland	1878–1882	17

In addition to furnishing materials for an approximately accurate estimate of the number of suicides which will occur in any country in a year, statistics have demonstrated that the proportion of male to female suicides is practically the same from year to year, viz. 3 or 4 males to 1 female; that it is possible to predict the month of greatest prevalence, the modes of death adopted by men on the one hand and women on the other, and even the relative frequency of suicide amongst persons following different professions and employments; and that in most of the countries of Europe the suicide-rate is increasing. In England and Wales the annual death-rate per million from suicide has steadily advanced, as is shown by the following figures for quinquennial periods:—

1861–1865	65 per million living.
1866–1870	66 " "
1871–1875	66 " "
1876–1880	74 " "
1881–1885	75 " "
1886–1890	79 " "
1891–1895	88 " "
1896–1900	89 " "
1901–1905	100 " "

The next table illustrates the continued increase in recent years, and at the same time shows the total number and the number of male and female suicides each year from 1886 to 1905.

TABLE II.

Total Suicides—Male and Female—in England and Wales, 1886–1905, together with the annual rate per million living (Registrar-General's Reports).

Year.	Male.	Female.	Total.	Suicide-rate per Million Living.
1886	1694	560	2254	82
1890	1635	570	2205	77
1895	2071	726	2797	92
1896	1979	677	2656	86
1897	2090	702	2792	90
1898	2166	711	2877	91
1899	2121	723	2844	89
1900	2166	730	2896	90
1901	2318	803	3121	96
1902	2460	807	3267	99
1903	2640	871	3511	105
1904	2523	822	3345	99
1905	2683	862	3545	104
Total.	28,546	9564	38,110	—

The reason of the high suicide-rate in some countries as compared with others, and the causes of its progressive increase, are not easily determined. Various explanations have been offered, such as the influence of climate, the comparative prevalence of insanity, and the proportionate consumption of alcoholic drinks, but none satisfactorily accounts for the facts. It may, however, be remarked that suicide is much more common amongst

Protestant than amongst Roman Catholic communities, while Jews have a smaller suicide-rate than Roman Catholics. A point of considerable interest is the increase of suicide in relation to the advance of elementary education. Ogle states that suicide is more common among the educated than the illiterate classes. It is also more prevalent in urban than in rural districts. A curious feature in large towns is the sudden outbreak of self-destruction which sometimes occurs, and which has led to its being described as epidemic. In such cases force of example and imitation undoubtedly play a considerable part, as it is well recognized that both these forces exert an influence not only in causing suicide, but also in suggesting the method, time and place for the act. No age above five years is exempted from furnishing its quota of suicidal deaths, although self-destruction between five and ten years is very rare. Above this age the proportion of suicides increases at each period, the maximum being reached between fifty-five and sixty-five. Among females there is a greater relative prevalence at earlier age periods than among males. The modes of suicide are found to vary very slightly in different countries. Hanging is most common amongst males; then drowning, injuries from fire-arms, stabs and cuts, poison and precipitation from heights. Amongst females, drowning comes first, while poison and hanging are more frequent than other methods entailing effusion of blood and disfigurement of the person. The methods used in England and Wales by suicides during 1888–1897, and in Scotland during the years 1881–1897, are given in the following table:—

TABLE III.

Modes of Suicide in England and Wales, 1888–1897.

Order of Frequency.	Males.		Females.		Both Sexes.	
	Mode.	Number.	Mode.	Number.	Mode.	Number.
1	Hanging	5669	Drowning	2089	Hanging	7005
2	Stab-cut	3594	Poison	1652	Drowning	5532
3	Drowning	3443	Hanging	1336	Stab-cut	4365
4	Poison	2264	Stab-cut	771	Poison	3916
5	Fire-arms	2152	Fire-arms	52	Fire-arms	2204
6	Otherwise	1773	Otherwise	527	Otherwise	2300
	Total	18,895	Total	6427	Total	25,322

Modes of Suicide in Scotland, 1881–1897.

Order of Frequency.	Males.		Females.		Both Sexes.	
	Mode.	Number.	Mode.	Number.	Mode.	Number.
1	Hanging	741	Drowning	430	Drowning	1060
2	Drowning	630	Hanging	257	Hanging	998
3	Stab-cut	556	Poison	145	Stab-cut	700
4	Poison	257	Stab-cut	144	Poison	402
5	Fire-arms	245	Fire-arms	6	Fire-arms	251
6	Otherwise	207	Otherwise	100	Otherwise	307
	Total	2636	Total	1082	Total	3718

The season of the year influences suicide practically uniformly in all European countries, the number increasing from the commencement of the year to a maximum in May or June, and then declining again to a minimum in winter. Morselli attempts to account for this greater prevalence during what may well be called the most beautiful months of the year by attributing it to the influence of increased temperature upon the organism, while Durkheim suggests that the determining factor is more probably to be found in the length of the day and the effect of a longer period of daily activity. The suicide-rate is higher in certain male occupations and professions than in others (Ogle). Thus it is high amongst soldiers, doctors, innkeepers and chemists, and low for clergy, bargemen, railway drivers and stokers. The suicide-rate is twice as great for unoccupied males as for occupied males.

(H. H. L.)

SŪÏDAS, Greek lexicographer. Nothing is known of him, except that he must have lived before Eustathius (12th–13th century), who frequently quotes him. Under the heading "Adam" the author of the lexicon (which a prefatory note states to be "by Sūïdas") gives a brief chronology of the world, ending with the death of the emperor John Zimisces (975), and under "Constantinople" his successors Basil and Constantine are mentioned. It would thus appear that Sūïdas lived in the latter part of the 10th century. The passages in which Michael Psellus (end of the 11th century) is referred to are considered later interpolations. The lexicon of Sūïdas is arranged alphabetically with some slight deviations, letters and combinations of letters having the same sound being placed together; thus, αι and ε follow δ, and ει, η, ι follow ζ. It partakes of the nature of a dictionary and encyclopaedia. It includes numerous quotations from ancient writers; the scholiasts on Aristophanes, Homer, Sophocles and Thucydides are also much used. The biographical notices, the author tells us, are condensed from the *Onomatologion* or *Pinax* of Hesychius of Miletus; other sources were the excerpts of Constantine Porphyrogenitus, the chronicle of Georgius Monachus, the biographies of Diogenes Laërtius and the works of Athenaeus and Philostratus. The work deals with scriptural as well as pagan subjects, from which it is inferred that the writer was a Christian. A prefatory note gives a list of dictionaries from which the lexical portion was compiled, together with the names of their authors. Although the work is uncritical and probably much interpolated, and the value of the articles is very unequal, it contains much information on ancient history and life.

Editio princeps, by Demetrius Chalcondyles (1499); later editions by L. Küster (1705), T. Gaisford (1834), G. Bernhardy (1834–1853) and I. Bekker (1854); see A. Daub, *De S. Biographicorum origine et fide* (1880) and *Studien zu den Biographika des S.* (1882); and J. E. Sandys, *Hist. of Cassical Scholarship* (1906), p. 407.

SUIDUN (Chinese, *Sui-din-chen*), a town of China, capital of the province of Kulja. It is the residence of the governor-general, and was founded in 1762 during the Mussulman rising, and rebuilt in 1883. It is a military town, with provision stores, an arsenal and an arms workshop. Its walls are armed with steel guns.

SUINA, a group of non-ruminating artiodactyle ungulate mammals typified by the swine (Suidae), but also including the hippopotamus (Hippopotamidae), and certain extinct forms. (See ARTIODACTYLA; HIPPOPOTAMUS; PECCARY; SWINE.)

SUITE (*Suite de pièces*; *Ordre*; *Partita*), in music, a group of dance tunes, mostly in binary form, of a type which may be described as "decorative" (see SONATA FORMS); constituting that classical form of early 18th-century instrumental music which most nearly foreshadows the later sonata. As understood by Bach, it consists essentially of four principal movements with the insertion of one or more lighter movements between the third and the last. The first movement is the *allemande*, of solid and intricate texture, in slow common time and rich flowing rhythm, beginning with one or three short notes before the first full bar. The second movement is the *courante*, of which there are two kinds. The French courante is again an intricate movement, also beginning with one or three notes before the main beat, and in a triple time ($\frac{3}{2}$) which, invariably at the cadences and sometimes elsewhere, drops into a crossing triple rhythm of twice the pace ($\frac{6}{4}$). The effect is restless and confused, and was supposed to form a contrast to the allemande; but it seldom did so effectively. Bach's study of Couperin led him to use the French courante frequently, but he was happier with the Italian type of *corrente*, which did not owe its name, like the French type, to the use of spasmodic runs, but was a brilliant continuously running piece in quick triple time ($\frac{3}{4}$ or $\frac{3}{8}$), forming a clear and lively contrast both to the allemande and to the third movement, which is generally a *sarabande*.

The *sarabande* is a slow movement in triple time beginning on the full bar, and with at least a tendency to the rhythm of which Handel's aria *Lascia ch'io pianga* is a familiar example.

Bach's sarabandes are among the most simply eloquent and characteristic of his smaller compositions. Then come the *galanteries*, from one to three in number. These are the only suite-movements which ever have an alternative section and a *da capo* (with the exception of Couperin's courantes and the courante in Bach's first English suite). The commonest galanteries are: (1) the *minuet*, often with a second minuet which is called "trio" only when it is in real three-part writing. It is a little faster than the stately minuet in Mozart's *Don Giovanni*, but it is never so quick as the lively minuets of Haydn's quartets and symphonies which led to the Beethoven scherzo; and it invariably begins, unlike many later minuets, on the full bar; (2) the *gavotte*, a lively dance in a not too rapid *alla breve* time (the textbooks say $\frac{4}{4}$ time, but there is no case in Bach which could possibly be played so slowly, whatever the time signature may be). The gavotte always begins on the half-bar. A second alternating gavotte is frequently founded on a pedal or drone-bass, and is then called *musette*; (3) the *bourrée*, which is not unlike the gavotte, but quicker, and beginning on the last quarter of the bar; (4) the *passepied*, a lively dance in quick triple time, beginning on the third beat. These dances are not always cast in binary form, and there are famous examples of gavottes and passepieds *en rondeau.* Other less common galanteries are (5) the *loure*,[1] a slow dance in $\frac{6}{4}$ time and dotted rhythm (dactylic in accent and amphimacer in quantity); (6) the *polonaise*, a leisurely triple-time piece, either a shade quicker or (as in the exquisite unattached examples of Friedemann Bach) much slower than the modern dance-rhythm of that name, with cadences on the second instead of the third beat of the bar; (7) the *air*, a short movement, quietly flowing, in a more florid style than its name would suggest. It sometimes precedes the sarabande. The suite concludes with a *gigue*, in the finest examples of which the decorative binary form is combined with a light fugue style of the utmost liveliness and brilliance. The gigue is generally in some triplet rhythm, *e.g.* $\frac{3}{8}$, $\frac{6}{8}$, $\frac{9}{8}$, $\frac{12}{8}$; but examples in a graver style may be found in slow square time with dotted rhythms, as in Bach's first French suite and the sixth Partita of the *Klavierübung*. In gigues in the typical fugato style Bach is fond of making the second part either invert the theme of the first, or else begin with a new subject to be combined with the first in double counterpoint. The device of inversion is also prominent in many of his allemandes and French courantes.

All suites on a large scale, with the exception of Bach's second and fourth solo violin sonatas, begin with a great prelude in some larger form. Bach's *French Suites* are small suites without prelude. His *English Suites* all have a great first movement which, except in the first suite, is in full *da capo* concerto form. His clavier *Partitas* show a greater variety of style in the dance movements and are preceded by preludes, in each case of a different type and title. Some large suites have finales after the gigue; the great chaconne for violin solo being the finale of a partita (see VARIATIONS).

Handel's suites are characteristically nondescript in form, but, in the probably earlier sets published after what is called his first set, there is a most interesting tendency to make several of the movements free variations of the first. Earlier composers had already shown the converse tendency to make variations take the forms of suite movements. In general Handel's suites are effective groups of movements of various lengths, with a tendency to use recognizable suite movements of a Franco-Italian type.

In modern times the term "suite" is used for almost any group of movements of which the last is in the same key as the first, and of which a fair proportion show traces of dance-rhythm, or at least use dance titles. It is often said that the suite-forms have shown more vitality under modern conditions than the classical sonata forms. But this only means that when composers do not feel inclined to write symphonies or sonatas they give their groups of movements the name of suite. Certainly there is no such thing as a definite modern suite-form distinguishable from the selection composers make, for use in concert rooms, of incidental music written for plays, such as Grieg's *Peer Gynt* suites. (D. F. T.)

[1] The *loure* of Bach's fifth French suite has in some editions been called the second *bourrée*, to the utter mystification of musicians.

SUKHUM-KALEH, a seaport of Russian Caucasia in the government of Kutais. Pop. (1900), about 16,000. It is situated 106 m. N. of Batum, and has the best roadstead on the east coast of the Black Sea, being sheltered by mountains on three sides and never freezing. In spite of the difficulties of communication with the interior, and the malarial marshes which surround the town, it has become important for the export of grain (chiefly maize). There is also a trade in tobacco. It stands on the site of the ancient Greek colony of Dioskurias. The annual mean temperature is 59° F. There are here a cathedral and a botanical garden. The town was captured by the Russians in 1809, but not formally relinquished by Turkey until 1829. In 1854 and again in 1877 it was occupied by the Turks.

SUKKUR, or SAKHAR, a town and district of British India, in Sind, Bombay. The town is situated on the right bank of the Indus, 24 m. N.W. of Skikarpur. Pop. (1901), 31,316. Sukkur has always commanded the trade of Sind, and the river is now crossed by a cantilever bridge carrying the North-Western railway to Kotri. The town was ceded to the Khairpur mirs between 1809 and 1824. In 1833 Shah Shuja defeated the Talpurs here with great loss. In 1842 it came under British rule.

The DISTRICT OF SUKKUR was created in 1901 out of part of Shikarpur district, the remainder of which was formed into the district of Larkana. Area, 5403 sq. m. It is chiefly alluvial plain, but there are slight hills at Sukkur and Rohri. In the higher-lying parts are salt lands (*Kalar*), or even desert in the area known as the Registan. The climate is hot, dry and enervating. The annual rainfall at Sukkur town averages only $4\frac{1}{2}$ in. The population in 1901 was 523,345, showing an increase of 10% in the decade. A considerable part of the district is irrigated, the principal crops being wheat, millets, rice, pulses and oil seeds. Earthen, leathern and metal ware, cotton cloth and tussore silk are manufactured, also pipe-bowls, snuff-boxes and scissors. Lines of the North-Western railway serve the district, and there is a branch from Sukkur towards Quetta.

SULA ISLANDS (Sulla, Xuila; Dutch *Soela*), a chain of islands forming a prolongation of the eastern peninsula of Celebes and the Banggai Islands, Dutch East Indies. The three main islands are long and narrow (Taliabu, 68 m. long, Mangoli or Mangala, 63 m. and Besi, 30 m.). The two first lie in line, separated by the narrow Chapalulu Strait; Besi extends at right angles to the south coast of Mangoli. The natives of Taliabu are allied to those of the Banggai Islands and the eastern peninsula of Celebes; but immigrant Malays are the principal inhabitants. Economically, Besi is the most important island. A Dutch commissioner resides at Sanana, at its northern extremity. It is fertile, and produces wax and honey, and coal has been found.

SULCI, an ancient town (mod. S. Antioco), situated on the east coast of an island on the south-west of Sardinia. The date of its foundation is not known, but it is certainly of Carthaginian origin. The assumption that it was originally an Egyptian colony is not justified. Its walls, of large rectangular blocks of stone, can be traced for a circuit of upwards of a mile: it extended to the low ground on the shore near the modern cemetery, where a dedicatory inscription set up by the people of Sulci in honour of Hadrian in A.D. 128 was found (F. Vivanet in *Notizie degli Scavi*, 1897, 407). Various discoveries have been made within the circuit, both of Phoenician and of Roman antiquities, including several statues[2] and inscriptions and many smaller objects, gems, &c., but at present few traces of ancient buildings are left, owing to their continued destruction in medieval and modern times. A cistern of fine masonry, perhaps dating from the Punic period,

[2] A statue of Drusus, the brother of Tiberius (?) was found in 1908.

in the low ground below the modern town, may be mentioned. Close to it, among the houses of the modern town, a solid base about 25 ft. square, belonging possibly to a lighthouse or a tomb, records the existence of a temple of Isis and Serapis during the imperial period. A bilingual inscription of the 1st century B.C. (?) in Latin and in neo-Punic records the erection of a statue to Himilkat, who had carried out a decree of the local *senatus* for the erection of a temple to a goddess (described in the Punic version as *domina dea*—possibly Tanit herself) by his son Himilkat (T. Mommsen in *Corp. inscr. lat.* x. 7513, 7514). The Phoenician tombs consist of a chamber cut in the rock, measuring about 14 ft. square and 8 ft. high, and approached by a staircase: some of these have been converted into dwellings in modern times. Many of the curious sculptured *stelae* found in these tombs are now in the museum of Cagliari. On many of them the goddess Tanit is represented, often in a form resembling Isis, which gave rise to the unfounded belief of the Egyptian origin of Sulci. The Roman tombs, on the other hand, are simply trenches excavated in the rock.

There are also several catacombs: a group still exists under the church, in which was discovered the body of the martyr St Antiochus, from whom the modern town takes its name. The church is cruciform, with heavy pillars between nave and aisles, and a dome over the crossing: it belongs to the Byzantine period, and contains an inscription of Torcotorius, protospatarius and Salusius, ἄρχων, dating from the 10th century A.D. (A. Taramelli in *Archivio storico sardo*, 1907, 83 sqq.). Others farther south-west were Jewish; they have inscriptions in red painted on the plaster with which they are lined, and the seven-branched candlestick occurs several times. The fort which occupies the highest point—no doubt the acropolis of the Punic period—is quite modern. The long, low isthmus which, with the help of bridges, connects the island with the mainland, is very likely in part or entirely of artificial origin; but neither it nor the bridges show any definite traces of Roman date. On either side of it ships could find shelter then as nowadays.

The origin of Sulci is attributed by Pausanias to the Carthaginians, and the Punic antiquities found there go to indicate the correctness of his account. It is mentioned in the account of the First Punic War as the place at which the Carthaginian admiral Hannibal took refuge after his defeat by C. Sulpicius, but was crucified. In 46 B.C. the city was severely punished by Caesar for the assistance given to Pompey's admiral Nasidius. Under the empire it was one of the most flourishing cities of Sardinia. It was attacked by the Vandals and Saracens, but ceased to exist before the 13th century. Previously to this it had been one of the four episcopal sees into which Sardinia was divided. A castle in the low ground, attributed to the index Torcotorius, to the south of the modern town, was destroyed in modern times.

See A. Tarawelli in *Notizie degli scavi* (1906), 135; (1908), 145, 192. (T. As.)

SULEIMAN I.[1] the "Magnificent" (1494–1566), sultan of Turkey, succeeded his father Selim I. in 1520. His birth coincided with the opening year of the 10th century of Mussulman chronology (A.H. 900), the most glorious period in the history of Islam. Eventful as the age was both in Europe, where the Renaissance was in full growth, and in India, where the splendour of the emperor Akbar's reign exceeded alike that of his predecessors and his successors, Suleiman's conquests overshadowed all these. It is noteworthy that though in Turkey he is distinguished only as the law-giver (*kanuni*), in European history he is known by such titles as the Magnificent. He was the most fortunate of the sultans. He had no rival worthy of the name. From his father he inherited a well-organized country, a disciplined army and a full treasury. He united in his person the best qualities of his predecessors, and possessed the gift of taking full advantage of the talents of the able generals, admirals and viziers who illustrated his reign. If his campaigns were not always so wisely and prudently planned as those of some of his predecessors, they were in the main eminently fortunate, and resulted in adding to his dominions Belgrade, Budapest, Temesvar, Rhodes, Tabriz, Bagdad, Nakshivan and Rivan, Aden and Algiers, and in his days Turkey attained the culminating point of her glory.

[1] Suleiman, eldest son of Bayazid I., who maintained himself as sultan at Adrianople from 1402 to 1410, is not reckoned as legitimate by the Ottoman historiographers, who reckon Suleiman the Magnificent as the first of the name. By others, however, the latter is sometimes styled Suleiman II.

The alliance concluded by him with France reveals him at once as rising superior to the narrow prejudices of his race and faith, which rejected with scorn any union with the unbeliever, and as gifted with sufficient political insight to appreciate the advantage of combining with Francis I. against Charles V. His Persian campaign was doubtless an error, but was due in part to a desire to find occupation, distant if possible, for his janissaries, who were always prone to turbulence while inactive at the capital. He was perhaps wanting in firmness of character, and the undue influence exercised over him by unscrupulous ministers, or by the seductions of fairer but no less ambitious votaries of statecraft, led him to make concessions which tarnished the glory of his reign, and were followed by baneful results for the welfare of his empire. It is from Suleiman's time that historians date the rise of that occult influence of the harem which has so often thwarted the best efforts of Turkey's most enlightened statesmen.

Suleiman's claims to renown as a legislator rest mainly on his organization of the Ulema, or clerical class, in its hierarchical order from the Sheikh-ul-Islam downwards. He reformed and improved the administration of the country both civil and military, inaugurated a new and improved system for the feudal tenures of limitary fiefs, and his amelioration of the lot of his Christian subjects is not his least title to fame. He was also not unknown to fame as a poet, under the pseudonym of "Muhibbr" (see Hammer-Purgstall, *Gesch. d. Osman. Reichs*, ii. 331; and further TURKEY: *History*).

Suleiman died on the 5th of September 1566, at the age of 72, while conducting the siege of Szigetvār.

SULEIMAN II. (1641–1691), sultan of Turkey, was a son of Sultan Ibrahim, and succeeded his brother Mahommed IV. in 1687. Forty-six years of enforced retirement had qualified him for the cloister rather than for the throne, and his first feeling when notified of his accession was one of terror for his brother's vengeance. Nor were the circumstances following on his elevation to the throne of a nature to reassure him, as one of the most violent of the revolts of the janissaries ended in the murder of the grand vizier and the brutal mutilation of his family, with general massacre and pillage throughout Constantinople. The war with Austria was for Turkey a succession of disasters. At this time, fortunately for the Ottoman Empire, a third great kuprili (Mustafa) arose and re-established order in the sorely-tried state (see KUPRILI). In the reforms which followed, whereby the situation of the Christian subjects of the Porte was greatly improved, Suleiman is at least to be given the credit of having allowed Mustafa Kuprili a free hand. With an improved administration Turkey's fortunes in the war began to revive, and the reconquest of Belgrade late in 1690 was the last important event of the reign, which ended in 1691 by Suleiman's death. (See also TURKEY: *History*.)

SULEIMANIEH, or SULEIMANIA, the chief town of a sanjak of the same name in Asiatic Turkey, in the vilayet of Mosul, situated on a treeless plain in the Kurdistan Mountains, in the region known as Shehrizor, some 40 or 50 m. from the Persian frontier, at an elevation of 2895 ft. It is a military station, and was founded towards the close of the 11th century. The estimated population is about 12,000, of whom 11,000 are Kurds, and the majority of the remaining 1000 Jews.

SULIMAN HILLS, a mountain system on the Dera Ismail Khan border of the north-west frontier of India. From the Gomal river southward commences the true Suliman system, presenting an impenetrable barrier between the plains of the Indus and Afghanistan. The Suliman Mountains finally merge into the hills of Baluchistan, which are inhabited by the Marri and Bugti tribes. The chief mass of the range is known as

Takht-i-Suliman or Solomon's throne. It may be seen on the western horizon from Dera Ismail Khan, a grey, flat-looking rampart rising from the lower line of mountains north and south of it, slightly saddle-backed in the middle, but culminating in a very well-defined peak at its northern extremity. The legend of the mountain is that Solomon visited Hindostan to marry Balkis, and that as they were returning through the air, on a throne supported by genii, the bride implored the bridegroom to let her look back for a few moments on her beloved land. Solomon directed the genii to scoop out a hollow for the throne on the summit of the mountain. The hollow is a cavity some 30 ft. square cut out of the solid rock, at the southern extremity of the mountain and is a place of pilgrimage for both Hindus and Mahommedans. The actual shrine is about two m. south of the highest peak. The whole mountain was traversed and surveyed by the Takht-i-Suliman Survey Expedition of 1883 (see SHERANI) and was found to consist of two parallel ridges running roughly north and south, the southern end of the eastern ridge culminating in a point 11,070 ft. high, which is the Takht proper on which the shrine is situated, and the western ridge culminating at its northern end in a point 11,300 ft. high known as Kaisargarh. Between these two ridges is a connecting tableland about 9000 ft. high. This plateau and the interior slopes of the ridges are covered with *chilghosa* (edible pine) forests. The mass of the mountain is composed of nummulitic limestone. No water is to be found on the summit.

SULINA, a town in Rumania, at the mouth of the Sulina branch of the Danube. Pop. (1900), 5611. Sulina is the only free port on the Danube, and is much used for the transhipment into sea-going vessels of grain which is brought down the river in large lighters from Rumania, Russia, Bulgaria, Servia and Austria-Hungary. No agricultural produce is grown in its neighbourhood, owing to the reed-covered swamps with which it is surrounded. Sulina is the headquarters of the technical department of the European Commission of the Danube (*q.v.*). Large steamers navigate up to Galatz and Braila. In 1901, 1411 steamers and sailing craft aggregating 1,830,000 tons register cleared from Sulina for European ports carrying, besides other merchandise, nearly 13,000,000 quarters of grain. Owing to the improvements effected by the European Commission, there is a depth of 24 ft. of water on the bar, and of 18 to 22 ft. in the fairway. A lighthouse overlooks the estuary. The town contains the only English church in Rumania.

SULITELMA, a mountain on the frontier between Norway and Sweden, forming a salient (6158 ft.) of the Kjöl or "keel" of the Scandinavian peninsula. The mass, composed of three peaks, is situated in 67° 10′ N., and covered with a snow-field from which many glaciers descend. In these rise feeders of the Swedish rivers Lilla Lule and Pite, flowing south-east. Westward, the foothills descend upon the Skjerstad Fjord, above which are two lakes, Nedre and Ovre Vand. From Sjönstaa steamers on the Langvand and a light railway give communication between the sea and Furulund, the headquarters of the Swedish Sulitelma Mining Company. A mountain track descends from Sulitelma to Kvickjock (or Kvikkjokk), a considerable village magnificently situated on the Tarrajock, a head-stream of the Lilla Lule. This is distant three days' journey on foot from Furulund.

SULLA, LUCIUS CORNELIUS (138–78 B.C.), surnamed *Felix*, Roman general, politician and dictator, belonged to a minor and impoverished branch of the famous patrician Cornelian gens. He received a careful education, and was a devoted student of literature and art. His political advancement was slow, and he did not obtain the quaestorship until 107, when he served in the Jugurthine war under Marius in Africa. In this he greatly distinguished himself, and claimed the credit of having terminated the war by capturing Jugurtha himself. In these African campaigns Sulla showed that he knew how to win the confidence of his soldiers, and throughout his career the secret of his success seems to have been the enthusiastic devotion of his troops, whom he continued to hold well in hand, while allowing them to indulge in plundering and all kinds of excess. From 104 to 101 he served again under Marius in the war with the Cimbri and Teutones and fought in the last great battle in the Raudian plains near Verona. It was at this time that Marius's jealousy of his legate laid the foundations of their future rivalry and mutual hatred. When the war was over, Sulla, on his return to Rome, lived quietly for some years and took no part in politics. In 93 he was elected praetor after a lavish squandering of money, and he delighted the populace with an exhibition of a hundred lions from Africa. Next year (92) he went as propraetor of Cilicia with special authority from the senate to make Mithradates VI. of Pontus restore Cappadocia to Ariobarzanes, one of Rome's dependants in Asia. Sulla with a small army soon won a victory over the general of Mithradates, and Rome's client-king was restored. An embassy from the Parthians now came to solicit alliance with Rome, and Sulla was the first Roman who held diplomatic intercourse with that remote people. In the year 91, which brought with it the imminent prospect of sweeping political change, with the enfranchisement of the Italian peoples, Sulla returned to Rome, and it was generally felt that he was the man to lead the conservative and aristocratic party.

Meanwhile Mithradates and the East were forgotten in the crisis of the Social or Italic War, which broke out in 91 and threatened Rome's very existence. The services of both Marius and Sulla were given; but Sulla was the more successful, or, at any rate, the more fortunate. Of the Italian peoples Rome's old foes the Samnites were the most formidable; these Sulla vanquished, and took their chief town, Bovianum. In recognition of this and other brilliant services, he was elected consul in 88, and brought the revolt to an end by the capture of Nola in Campania. The question of the command of the army against Mithradates again came to the front. The senate had already chosen Sulla; but the tribune Publius Sulpicius Rufus moved that Marius should have the command. Rioting took place at Rome at the prompting of the popular leaders, Sulla narrowly escaping to his legions in Campania, whence he marched on Rome, being the first Roman who entered the city at the head of a Roman army. Sulpicius was put to death, and Marius fled; and he and his party were crushed for the time.

Sulla, leaving things quiet at Rome, quitted Italy in 87, and for the next four years he was winning victory after victory against the armies of Mithradates and accumulating boundless plunder. Athens, the headquarters of the Mithradatic cause, was taken and sacked in 86; and in the same year, at Chaeroneia, the scene of Philip II. of Macedon's victory more than two and a half centuries before, and in the year following, at the neighbouring Orchomenus, he scattered immense hosts of the enemy with trifling loss to himself. Crossing the Hellespont in 84 into Asia, he was joined by the troops of C. Flavius Fimbria, who soon deserted their general, a man sent out by the Marian party, now again in the ascendant at Rome. The same year peace was concluded with Mithradates on condition that he should be put back to the position he held before the war; but, as he raised objections, he had in the end to content himself with being simply a vassal of Rome.

Sulla returned to Italy in 83, landing at Brundisium, having previously informed the senate of the result of his campaigns in Greece and Asia, and announced his presence on Italian ground. He further complained of the ill-treatment to which his friends and partisans had been subjected during his absence. Marius had died in 86, and the revolutionary party, specially represented by L. Cornelius Cinna, Cn. Papirius Carbo and the younger Marius, had massacred Sulla's supporters wholesale, confiscated his property, and declared him a public enemy. They felt they must resist him to the death, and with the troops scattered throughout Italy, and the newly enfranchised Italians, to whom it was understood that Sulla was bitterly hostile, they counted confidently on success. But on Sulla's advance at the head of his 40,000 veterans many of them lost heart and deserted their leaders, while the Italians themselves, whom he confirmed in their new privileges, were won over to his side. Only the Samnites, who were as yet without the Roman franchise, remained his enemies, and it seemed as if the old war between Rome and Samnium had to be fought once again. Several Roman nobles, among them Gnaeus Pompeius (Pompey the Great), Q. Caecilius Metellus Pius, Marcus Licinius Crassus, Marcus Licinius Lucullus, joined Sulla, and in the following year (82) he won a decisive victory over the younger Marius near Praeneste (mod. Palestrina) and then marched upon Rome, where again, just before his defeat of Marius, there had been a great massacre of his adherents, in which the learned jurist Q. Mucius Scaevola perished. Rome was at the same time in extreme peril from the advance of a Samnite army, and was barely saved by Sulla, who, after a hard-fought battle, routed the enemy under Pontius Telesinus at the Colline gate of Rome. With the death of the younger Marius, who killed himself after the surrender of Praeneste, the civil war was at an end, and Sulla was master of Rome and of the Roman world. Then came the memorable "proscription," when for the first time in Roman history a list of men declared to be outlaws and public enemies was exhibited in the forum, and a reign of terror began throughout Rome and Italy. The title of "dictator" was revived and Sulla was in fact emperor of Rome. After celebrating a splendid triumph for the Mithradatic War, and assuming the surname of "Felix" ("Epaphroditus," "Venus's favourite,"[1] he styled himself in addressing Greeks), he carried in 80 and 79 his great political reforms (see ROME: *History*, II. "*The Republic*"). The main object of these was to invest the senate, which he recruited with a number of his own party, with full control over the state, over every magistrate and every province; and the mainstay of his political system was to be the military colonies which he had established with grants of land throughout every part of Italy, to the ruin of the old Italian freeholders and farmers, who from this time dwindled away, leaving whole districts waste and desolate.

In 79 Sulla resigned his dictatorship and retired to Puteoli (mod. Pozzuoli), where he died in the following year, probably from the bursting of a blood-vessel. The story that he fell a victim to a disease similar to that which cut off one of the Herods (Acts xii. 23) is probably an invention of his enemies. The "half lion, half fox," as his enemies called him, the "Don Juan of politics" (Mommsen), the man who carried out a policy of "blood and iron" with a grim humour, amused himself in his last days with actors and actresses, with dabbling in poetry, and completing the *Memoirs* (*commentarii*, ὑπομνήματα) of his eventful life (see H. Peter, *Historicorum romanorum reliquiae*, 1870). Even then he did not give up his interest in state and local affairs, and his end is said to have been hastened by a fit of passion brought on by a remark of the quaestor Granius, who openly asserted that he would escape payment of a sum of money due to the Romans, since Sulla was on his death-bed. Sulla sent for him and had him strangled in his presence; in his excitement he broke a blood-vessel and died on the following day. He was accorded a magnificent public funeral, his body being removed to Rome and buried in the Campus Martius. His monument bore an inscription written by himself, to the effect that he had always fully repaid the kindnesses of his friends and the wrongs done him by his enemies. His military genius was displayed in the Social War and the campaigns against Mithradates; while his constitutional reforms, although doomed to failure from the lack of successors to carry them out, were a triumph of organization. But he massacred his enemies in cold blood, and exacted vengeance with pitiless and calculated cruelty; he sacrificed everything to his own ambition and the triumph of his party.

The ancient authorities for Sulla and his time are his *Life* by Plutarch (who made use of the *Memoirs*); Appian, *Bell. civ.*; for the references in Cicero see Orelli's *Onomasticon Tullianum*. Modern treatises by C. S. Zachariä, *L. Cornelius S. als Ordner des römischen Freystaates* (1834); T. Lau, *Lucius Cornelius Sulla* (1855); E. Linden, *De bello civili Sullano* (1896); P. Cantalupi, *La Guerra civile Sullana in Italia* (1892); C. W. Oman, *Seven Roman Statesmen* (1902); F. D. Gerlach, *Marius und Sulla* (1856); J. M. Sunden, "De tribunicia potestate a Lucio Sulla imminuta" in *Skrifter utgifna af k. humanistika Vetenskapssamfundet i Upsala*, v., 1897, in which it is argued against Mommsen that Sulla did not deprive the tribunes of the right of proposing rogations. See also Mommsen's *History of Rome*, vol. iii., bk. iv., ch., 8, 9; Drumann, *Geschichte Roms*, 2nd ed. by Groebe, ii. 364-432; Pauly-Wissowa, *Realencyclopädie*, iv. 1522-1566 (Fröhlich).

[1] A short epigram on Aphrodite in the *Greek Anthology* (Anth. Pal., *Appendix*, i. 153) is ascribed to him.

His nephew (as some say, though the degree of relationship cannot be clearly established), PUBLIUS CORNELIUS SULLA was consul in 66 B.C. with P. Autronius Paetus. Both were convicted of bribery, and Paetus subsequently joined Catiline in his first conspiracy. There is little doubt that Sulla also was implicated; Sallust does not mention it, but other authorities definitely assert his guilt. After the second conspiracy he was accused of having taken part in both conspiracies. Sulla was defended by Cicero and Hortensius, and acquitted. There is no doubt that, after his first conviction, Sulla remained very quiet, and, whatever his sympathies may have been, took no active part in the conspiracy. When the civil war broke out, Sulla took the side of Caesar, and commanded the right wing at the battle of Pharsalus. He died in 45.

See Cicero, *Pro Sulla, passim* (ed. J. S. Reid, 1882); *Ad Fam.* ix. 10, xv. 17; Dio Cassius xxxvi. 44, xxxvii. 25; Suetonius, *Caesar*, 9; Caesar, *Bell. civ.*, iii. 51, 89; Appian, *Bell. civ.* ii. 76.

SULLIVAN, SIR ARTHUR SEYMOUR (1842–1900), English musical composer, was born in London on the 13th of May 1842, being the younger of the two sons of Thomas Sullivan, a cultivated Irish musician who was bandmaster at the Royal Military College, Sandhurst, from 1845 to 1856, and taught at the Military School of Music at Kneller Hall from 1857 till his death in 1866. His mother, *née* Mary Coghlan (1811–1882), had Italian blood in her veins. Arthur Sullivan was brought up to music from boyhood, and he had learnt to play every wind instrument in his father's band by the age of eight. He was sent to school at Bayswater till he was twelve, and then, through Sir George Smart, he was, at his own persistent request, made a Chapel Royal chorister, and entered Mr Helmore's school for Chapel Royal boys in Cheyne Walk. He had a fine treble voice, and sang with exceptional taste. In 1856 the Mendelssohn Scholarship at the Royal Academy of Music was thrown open for the first time for competition, and was won by Sullivan, his nearest rival being Joseph Barnby. At the Academy he studied under Sterndale Bennett, Arthur O'Leary and John Goss, and did so well that he was given an extension of his scholarship for two years in succession. In 1858, his voice having broken, he was enabled by means of his scholarship to go to study at the conservatorium of Leipzig. There he had for teachers Moscheles and Plaidy for pianoforte, Hauptmann for counterpoint, Rietz and Reinecke for composition, and F. David for orchestral playing and conducting. Among his fellow-students were Grieg, Carl Rosa, Walter Bache, J. F. Barnett and Edward Dannreuther. Instead of the Mendelssohn *cultus* which represented orthodoxy in London, German musical interest at this period centred in Schumann, Schubert and the growing reputation of Wagner, whilst Liszt and Von Bülow were the celebrities of the day. Sullivan thus became acquainted for the first time with masterpieces which were then practically ignored in England. He entered enthusiastically into the spirit of the place, and after two years' hard study returned to London in April 1861. Before doing so, however, he had composed his incidental music for *The Tempest*, which he had begun as a sort of diploma work. Sullivan set himself to find converts in London to the enthusiasms he had imbibed at Leipzig. He became acquainted with George Grove, then secretary of the Crystal Palace, and August Manns, the conductor there; and at his instigation Schumann's First Symphony was introduced at one of the winter concerts. Early in 1862 Sullivan showed Grove and Manns his *Tempest* music, and on the 5th of April it was performed at the Crystal Palace. The production was an unmixed triumph, and Sullivan's exceptional gifts as a composer were generally recognized from that moment. He had hitherto been occupying himself with teaching, and he continued for some years to act as organist at St Michael's, Chester Square, but henceforth he devoted most of his time to composition. By 1864 he had produced his "Kenilworth" cantata (remembered chiefly for the lovely duet, "How sweet the Moonlight"), the "Sapphire Necklace" overture, and the five beautiful songs from Shakespeare, which include

" Orpheus with his Lute," "Oh Mistress Mine" and "The Willow Song." His attractive personality, combined with his undoubted genius and brilliant promise, brought him many friends. Costa, who was conductor at Covent Garden, gave him the post of organist, and in 1864 he produced there his *L'Île Enchantée* ballet. Some of his spare time was spent in Ireland, where in 1863 he began the composition of his (" Irish ") Symphony in E, which was produced at the Crystal Palace in 1866. The most important event, however, at this period, as bearing upon his later successes, was his co-operation with F. C. Burnand in the musical extravaganza *Cox and Box*, which first showed his capacity for musical drollery. This was acted privately in 1866, and was completed for public performance in 1867, in which year Sullivan again co-operated with Burnand in *Contrabandista*. Meanwhile he was in request as a conductor, and was made professor of composition at the Academy. His father's sudden death in 1866 inspired him to write the fine " In Memoriam " overture, which was produced at the Norwich Festival. In 1867, besides producing his " Marmion " overture, he and Grove did a great service to their art by bringing to light at Vienna a number of lost Schubert MSS., including the *Rosamunde* music. About this time Sullivan induced Tennyson to write his song-cycle " The Window," to be illustrated by Millais, with music by himself. But Millais abandoned the task, and Tennyson was not happy about his share; and the series, published in 1871, never became popular, in spite of Sullivan's dainty setting. In 1869 he brought out his oratorio *The Prodigal Son* at Worcester, and in 1870 his overture " Di Ballo " at Birmingham.

In 1871 Sullivan had become acquainted with W. S. Gilbert (*q.v.*), and in 1872 they collaborated in a piece for the Gaiety Theatre, called *Thespis; or, The Gods Grown Old*, which was a great success in spite of the limited vocal resources of the performers. In 1875 R. D'Oyly Carte, then acting as manager for Selina Dolaro at the Royalty, approached Gilbert with a view to his collaborating with Sullivan in a piece for that theatre. Gilbert had already suggested to Sullivan an operetta with its scene in a law court, and within three weeks of his completing the libretto of *Trial by Jury* the music was written. The piece succeeded beyond all expectation; and on the strength of its promise of further successes D'Oyly Carte formed his Comedy Opera Company and took the Opéra Comique Theatre. There in 1877 *The Sorcerer* was produced, George Grossmith and Rutland Barrington being in the cast. In 1878 *H.M.S. Pinafore* was brought out at the Opéra Comique. At first it did not attract large audiences, but eventually it became a popular success, and ran for 700 nights. In America it was enthusiastically received, and the two authors, with D'Oyly Carte, went over to the States in 1879, with a company of their own, in order to produce it in New York. To secure the American rights for their next opera, they brought out *The Pirates of Penzance* first at New York in 1879. In 1880, in London, it ran for nearly 400 nights. In 1881 *Patience* was produced at the Opéra Comique, and was transferred later in the year to the Savoy Theatre. There all the later operas came out: *Iolanthe* (1882), *Princess Ida* (1884), *The Mikado*—perhaps the most charming of all—(1885), *Ruddigore* (1887), *The Yeomen of the Guard* (1888), *The Gondoliers* (1889). This succession of pieces by Gilbert and Sullivan had made their united names stand for a new type of light opera. Its vogue owed something to such admirable performers as George Grossmith—famous for his " patter songs "—Rutland Barrington, Miss Jessie Bond, Miss Brandram, and later W. H. Denny and Walter Passmore; but these artistes only took advantage of the opportunities provided by the two authors. In place of the old adaptations of French *opéra bouffe* they had substituted a genuinely English product, humorous and delightful, without a tinge of vulgarity or the commonplace. But disagreements now arose between them which caused a dissolution of partnership. Sullivan's next Savoy opera, *Haddon Hall* (1892), had a libretto by Sydney Grundy; and the resumption of Gilbert's collaboration in 1893 in *Utopia, Limited*, and again in 1896 in *The Grand Duke*, was not as successful as before. Sullivan's music, however, still showed its characteristic qualities in *The Chieftain* (1894)—largely an adaptation of *Contrabandista*; *The Beauty Stone* (1898), with a libretto by A. W. Pinero and J. Comyns Carr; and particularly in *The Rose of Persia* (1900), with Captain Basil Hood.

In the public mind Sir Arthur Sullivan (who was knighted in 1883) had during these years become principally associated with the enormous success of the Savoy operas; but these by no means exhausted his musical energies. In 1872 his *Te Deum* for the recovery of the prince of Wales was performed at the Crystal Palace. In 1873 he produced at the Birmingham Musical Festival his oratorio *The Light of the World*, in 1877 he wrote his incidental music to *Henry VIII.*, in 1880 his sacred cantata *The Martyr of Antioch*, and in 1886 his masterpiece, *The Golden Legend*, was brought out at the Leeds Festival. *The Golden Legend* satisfied the most exacting critics that for originality of conception and grandeur of execution English music possessed in Sullivan a composer of the highest calibre. In 1891, for the opening of D'Oyly Carte's new English opera-house in Shaftesbury Avenue he wrote his " grand opera" *Ivanhoe* to a libretto by Julian Sturgis. The attempt to put an English opera on the stage for a long run was doomed to failure, but *Ivanhoe* was full of fine things. In 1892 he composed incidental music to Tennyson's *Foresters*. In 1897 he wrote a ballet for the Alhambra, called *Victoria and Merrie England*. Among his numerous songs, a conspicuous merit of which is their admirable vocal quality, the best known are " If Doughty Deeds " (1866), " The Sailor's Grave " (1872), " Thou'rt Passing Hence " (1875), " I would I were a King " (1878), " King Henry's Song " (1878) and " The Lost Chord " (1877). This last, hackneyed as it became, was probably the most successful English song of the 19th century. It was written in 1877, during the fatal illness of Sullivan's brother Frederic, who, originally an architect, had become an actor, and by means of his fine voice and powers as a comedian (best shown as the Judge in *Trial by Jury*) had won considerable success. Among Sullivan's many hymn tunes, the stirring " Onward, Christian Soldiers! " (1872) is a permanent addition to Church music. In 1876 he accepted the principalship of the National Training School of Music, which he held for six years; this was the germ of the subsequent Royal College. He received the honorary degree of Mus. Doc. from Cambridge (1876) and Oxford (1879). In 1878 he was a member of the royal commission for the Paris Exhibition. He was conductor of the Leeds Festivals from 1879 to 1898, besides being conductor of the Philharmonic Society in 1885. Apart from his broad sympathy and his practical knowledge of instruments, his work as a conductor must always be associated with his efforts to raise the standard of orchestral playing in England and his unwearying exertions on behalf of British music and British musicians. Sullivan liked to be associated in the public mind with patriotic objects, and his setting of Rudyard Kipling's " Absent-minded Beggar " song, at the opening of the Boer War in 1899, was, with the exception of *The Rose of Persia*, the last of his compositions brought out in his lifetime. He died somewhat suddenly of heart failure on the 22nd of November 1900, and his burial in St Paul's Cathedral was the occasion of a remarkable demonstration of public sorrow. He left unpublished a *Te Deum* written for performance at the end of the Boer War, and an unfinished Savoy opera for a libretto by Captain Hood, which, completed by Edward German, was produced in 1901 as *The Emerald Isle*.

Sullivan was the one really popular English composer of any artistic standing in his time; and his celebrity as a public man has somewhat interfered with a definite judgment as to his place in the history of English music. In his own time, English musical taste developed in a very remarkable degree; and musical criticism in serious quarters was a little disinclined to do justice to what was " popular." One of the most agreeable companions, broad-minded, and free from all affectation, he was intensely admired and loved in all circles of society; and though his health was not robust, for he suffered during many years at intervals from a painful ailment, he was a man of the world who enjoyed the life which his success opened out to him without being spoilt by it. He was always a devoted and an industrious musician, and from the day he left Leipzig his influence was powerfully exerted in favour of a wider and fuller recognition of musical culture. He was accused in some quarters of being unsympathetic towards Wagner and the post-Wagnerians, yet he had been one of the first to introduce Wagner's music to English audiences. He was keenly appreciative of new talent, but his tastes were too eclectic to satisfy the enthusiasts for any particular school; he certainly had no liking for what he considered uninspired academic writing. Serious critics deplored, with more justification, that he should have devoted so much of his great natural gift not merely to light comic opera, but to the production of a number of songs which, though always musicianly, were really of the nature of "pot-boiling." Sullivan was an extremely rapid worker, and his fertility in melody made it easy for him to produce what would please a large public. Moreover, it must be admitted that his great social success, so early achieved, was not calculated to nourish a rigidly artistic ideal. But when all is said, his genius remains undisputed; and it was a genius essentially English. His church music alone would entitle him to a high place among composers; and *The Golden Legend*, *Ivanhoe*, the *In Memoriam* overture, the "Irish" symphony and the charming "incidental music" to *The Tempest* and to *Henry VIII.* form a splendid legacy of creative effort, characterized by the highest scholarly qualities in addition to those beauties which appeal to every ear. Whether his memory will be chiefly associated with these works, or rather with the world-wide popularity of some of his songs and comic operas, time alone can tell. The Savoy operas did not aim at intellectual or emotional grandeur, but at providing innocent and wholesome pleasure; and in giving musical form to Gilbert's witty librettos Sullivan showed once for all what light opera may be when treated by the hand of a master. His scores are as humorous and fanciful *quâ* music as Gilbert's verses are *quâ* dramatic literature. Bubbling melody, consummate orchestration, lovely songs and concerted pieces (notably the famous vocal quintets) flowed from his pen in unexhausted and inimitable profusion. If he had written nothing else, his unique success in this field would have been a solid title to fame. As it was, it is Sir Arthur Sullivan's special distinction not only to have been prolific in music which went straight to the hearts of the people, but to have enriched the English *répertoire* with acknowledged masterpieces, which are no less remarkable for their technical accomplishment.

See also *Sir Arthur Sullivan: Life-story, Letters, and Reminiscences*, by Arthur Lawrence (London: Bowden, 1899). Besides being largely autobiographical, this volume contains a complete list of Sullivan's works, compiled by Mr Wilfrid Bendall, who for many years acted as Sir Arthur's private secretary. (H. Ch.)

SULLIVAN, JOHN (1740–1795), American soldier and political leader, was born in Somersworth, New Hampshire, on the 18th of February 1740. He studied law in Portsmouth, N.H., and practised at Berwick, Maine, and at Durham, N.H. He was a member of the New Hampshire Provincial Assembly in 1774, and in 1774–1775 was a delegate to the Continental Congress. In 1772 he had been commissioned a major of New Hampshire militia, and on the 15th of December 1774 he and John Langdon led an expedition which captured Fort William and Mary at New Castle. Sullivan was appointed a brigadier-general in the Continental army in June 1775 and a major-general in August 1776. He commanded a brigade in the siege of Boston. In June 1776 he took command of the American army in Canada and after an unsuccessful skirmish with the British at Three Rivers (June 8) retreated to Crown Point. Rejoining Washington's army, he served under General Israel Putnam in the battle of Long Island (August 27) and was taken prisoner. Released on parole, he bore a verbal message from Lord Howe to the Continental Congress, which led to the fruitless conference on Staten Island. In December he was exchanged, succeeded General Charles Lee in command of the right wing of Washington's army, in the battle of Trenton led an attack on the Hessians, and led a night attack against British and Loyalists on Staten Island, on the 22nd of August 1777. In the battle of Brandywine (Sept. 11, 1777) he again commanded the American right; he took part in the battle of Germantown (Oct. 4, 1777); in March 1778 he was placed in command in Rhode Island, and in the following summer plans were made for his co-operation with the French fleet under Count d'Estaing in an attack on Newport, which came to nothing. Sullivan after a brief engagement (Aug. 29) at Quaker Hill, at the N. end of the island of Rhode Island, was obliged to retreat. In 1779 Sullivan, with about 4000 men, defeated the Iroquois and their Loyalist allies at Newtown (now Elmira), New York, on the 29th of August, burned their villages, and destroyed their orchards and crops. Although severely criticised for his conduct of the expedition, he received, in October 1779, the thanks of Congress. In November he resigned from the army. Sullivan was again a delegate to the Continental Congress in 1780–1781 and, having accepted a loan from the French minister, Chevalier de la Luzerne, he was charged with being influenced by the French in voting not to make the right to the north-east fisheries a condition of peace. From 1782 to 1785 he was attorney-general of New Hampshire. He was president of the state in 1786–1787 and in 1789, and in 1786 suppressed an insurrection at Exeter immediately preceding the Shays Rebellion in Massachusetts. He presided over the New Hampshire convention which ratified the Federal constitution in June 1788. From 1789 until his death at Durham, on the 23rd of January 1795, he was United States District Judge for New Hampshire.

Amory, *General John Sullivan, A Vindication of his Character as a Soldier and a Patriot* (Morrisania, N.Y., 1867); John Scales, "Master John Sullivan of Somersworth and Berwick and his Family," in the *Proceedings of the New Hampshire Historical Society*, vol. iv. (Concord, 1906); and *Journals of the Military Expedition of Major-General John Sullivan against the Six Nations of Indians* (Auburn, N. Y., 1887).

SULLIVAN, THOMAS BARRY (1824–1891), Irish actor, was born at Birmingham, and made his first stage appearance at Cork about 1840. His earliest successes were in romantic drama, for which his graceful figure and youthful enthusiasm fitted him. His first London appearance was in 1852 in *Hamlet*, and he was also successful as Angiolo in Miss Vandenhoff's *Woman's Heart*, Evelyn in *Money* and Hardman in Lord Lytton's *Not so Bad as we Seem*. Claude Melnotte—with Helen Faucit as Pauline—was also a notable performance. A tour of America in 1857 preceded his going to Australia (1861) for six years, as actor and manager. He completed a trip round the world in 1866. From 1868–1870 he managed the Holborn theatre, where Beverley in *The Gamester* was one of his most powerful impersonations. Afterwards he travelled over the United States, Canada, Australia and England. Among his later London performances were several Shakespearian parts, his best, perhaps, being Richard III. He was the Benedick of the cast of *Much Ado About Nothing* with which the Shakespeare Memorial was opened at Stratford-on-Avon. He died on the 3rd of May 1891.

SULLY, JAMES (1842–), English psychologist, was born on the 3rd of March 1842 at Bridgwater, and was educated at the Independent College, Taunton, the Regent's Park College, Göttingen and Berlin. He was originally destined for the Nonconformist ministry, but in 1871 adopted a literary and philosophic career. He was Grote professor of the philosophy of mind logic at University College, London, from 1892 to 1903, when he was succeeded by Carveth Read. An adherent of the associationist school of psychology, his views had great affinity with those of Alexander Bain. His monographs, as that on pessimism, are ably and readably written, and his textbooks, of which *The Human Mind* (1892) is the most important, are models of sound exposition.

Works.—*Sensation and Intuition* (1874), *Pessimism* (1877), *Illusions* (1881; 4th ed., 1895), *Outlines of Psychology* (1884; many editions), *Teacher's Handbook of Psychology* (1886), *Studies of Childhood* (1895), *Children's Ways* (1897), and *An Essay on Laughter* (1902).

SULLY, MAXIMILIEN DE BÉTHUNE, Duc de (1560–1641), French statesman, was born at the château of Rosny near Mantes, on the 13th of December 1560, of a noble family of Flemish descent. His father, François de Béthune, baron de Rosny, (1532–1575), was the son of Jean de Béthune, to whom in 1529 his wife Anne de Melun brought as part of her dowry a seigneurie at Rosny-sur-Seine, which later (1601) was made a marquisate. Brought up in the Reformed faith, Maximilien was presented to Henry of Navarre in 1571 and was thenceforth attached to the future king of France. The young baron de Rosny was taken to Paris by his patron and was studying at the college of Bourgogne at the time of the massacre of St Bartholomew's Day, from which he escaped by discreetly carrying a book of hours under his arm. He then studied mathematics and history at the court of Henry of Navarre, and on the outbreak of civil war in 1575 he enlisted in the Protestant army. In 1576 he accompanied the duke of Anjou on an expedition into the Netherlands in order to regain the former Rosny estates, but being unsuccessful he attached himself for a time to the prince of Orange. Later rejoining Henry of Navarre in Guienne, he displayed bravery in the field and particular ability as an engineer. In 1583 he was Henry's special agent in Paris. In 1584 he married Anne de Courtenay, a wealthy heiress, who died, however, in 1589. On the renewal of civil war Rosny again joined Henry of Navarre, and at the battle of Ivry (1590) was seriously wounded. He counselled Henry IV.'s conversion to Roman Catholicism, but steadfastly refused himself to become a Roman Catholic. As soon as Henry's power was established, the faithful and trusted Rosny received his reward in the shape of numerous estates and dignities. On the death of D'O, the superintendent of finances, in 1594, the king had appointed a finance commission of nine members, to which he added Rosny in 1596. The latter at once made a tour of inspection through the generalities, and introduced some order into the country's affairs. He was probably made sole superintendent of finances in 1598, although this title does not appear in official documents until the close of 1601. He authorized the free exportation of grain and wine, reduced legal interest from $8\frac{1}{3}$ to $6\frac{1}{4}$%, established a special court for the trial of cases of peculation, forbade provincial governors to raise money on their own authority, and otherwise removed many abuses of tax-collecting, abolished several offices, and by his honest, rigorous conduct of the country's finances was able to save between 1600 and 1610 an average of a million livres a year. His achievements were by no means solely financial. In 1599 he was appointed grand commissioner of highways and public works, superintendent of fortifications and grand master of artillery; in 1602 governor of Mantes and of Jargeau, captain-general of the queen's gens d'armes and governor of the Bastille; in 1604 governor of Poitou; and in 1606 duke and peer of Sully, ranking next to princes of the blood. He declined the office of constable because he would not become a Roman Catholic. Sully encouraged agriculture, urged the free circulation of produce, promoted stock-raising, forbade the destruction of the forests, drained swamps, built roads and bridges, planned a vast system of canals and actually began the canal of Briare. He strengthened the French military establishment; under his direction Évrard began the construction of a great line of defences on the frontiers. Sully opposed the king's colonial policy as inconsistent with the French genius, and likewise showed little favour to industrial pursuits, although on the urgent solicitation of the king he established a few silk factories. He fought in company with Henry IV. in Savoy (1600–1601) and negotiated the treaty of peace in 1602; in 1603 he represented Henry at the court of James I. of England; and throughout the reign he helped the king to put down insurrections of the nobles, whether Roman Catholic or Protestant. It was Sully, too, who arranged the marriage between Henry IV. and Marie de Médicis.

The political rôle of Sully practically ended with the assassination of Henry IV. on the 14th of May 1610. Although a member of the council of regency, his colleagues were not disposed to brook his domineering leadership, and after a stormy debate he resigned as superintendent of finances on the 26th of January 1611, and retired to private life. The queen-mother gave him 300,000 livres for his services and confirmed him in possession of his estates. He attended the estates-general in 1614, and on the whole was in sympathy with the policy and government of Richelieu. He disavowed the plots at La Rochelle, in 1621, but in the following year was arrested at Moulins, though soon released. The baton of marshal of France was conferred on him on the 18th of September 1634. The last years of his life were spent chiefly at Villebon, Rosny and Sully. He died at Villebon, on the 22nd of December 1641. By his first wife Sully had one son, Maximilien, marquis de Rosny (1587–1634), who led a life of dissipation and debauchery. By his second wife, Rachel de Cochefilet, widow of the lord of Châteaupers, whom he married in 1592 and who turned Protestant to please him, he had nine children, of whom six died young, and one daughter married in 1605 Henri de Rohan.

Sully was not popular. He was hated by most Roman Catholics because he was a Protestant, by most Protestants because he was faithful to the king, and by all because he was a favourite, and selfish, obstinate and rude. He amassed a large personal fortune, and his jealousy of all other ministers and favourites was extravagant. Nevertheless he was an excellent man of business, inexorable in punishing malversation and dishonesty on the part of others, and opposed to the ruinous court expenditure which was the bane of almost all European monarchies in his day. He was gifted with executive ability, with confidence and resolution, with fondness for work, and above all with deep devotion to his master. He was implicitly trusted by Henry IV. and proved himself the most able assistant of the king in dispelling the chaos into which the religious and civil wars had plunged France. To Sully, next to Henry IV., belongs the credit for the happy transformation in France between 1598 and 1610 by which agriculture and commerce were benefited and foreign peace and internal order were maintained.

Sully left a curious collection of memoirs written in the second person and bearing the quaint title, *Mémoires des sages et royales œconomies d'estat, domestiques, politiques, et militaires de Henry le Grand, l'exemplaire des roys, le prince des vertus, des armes, et des loix, et le père en effet de ses peuples françois; et des servitudes utiles, obissances convenables, et administrations loyales de Maxim. de Béthune, l'un des plus confidens, familiers, et utiles soldats et serviteurs du grand Mars des François: dédiées à la France, à tous les bons soldats, et tous peuples françois.* The memoirs are very valuable for the history of the time and as an autobiography of Sully, in spite of the fact that they contain many fictions, such as a mission undertaken by Sully to Queen Elizabeth in 1601, and the famous "Grand Design," a plan for a Christian republic, which some historians have taken seriously. Two folio volumes of the memoirs were splendidly printed, nominally at Amsterdam, but really under Sully's own eye, at his château in 1638; two other volumes appeared posthumously in Paris in 1662. The abbé de l'Écluse rewrote the memoirs in ordinary narrative form and edited them in 1745. The best edition of the original is that in J. F. Michaud and J. J. F. Poujoulat, *Nouvelle collection des mémoires relatifs à l'histoire de France* (1854), vols. xvi.–xvii. An English translation by Charlotte Lennox appeared in 1756 and was later revised and republished (4 vols., London, 1856).

SULLY, THOMAS (1783–1872), American artist, was born at Horncastle, England, on the 8th of June 1783. His parents, who were actors, took him to America when he was nine years old, settling at Charleston, South Carolina, and he was first instructed in art by a French miniature painter. Afterwards he was a pupil of Gilbert Stuart in Boston, and in 1809 he went to London and entered the studio of Benjamin West. He returned in 1810, and made Philadelphia his home, but in 1837 again visited London, where he painted a full length portrait of Queen Victoria for the St George's Society of Philadelphia. Sully was one of the best of the early American painters. He died in Philadelphia on the 5th of November 1872. Among his portraits are those of Commodore Decatur (City Hall, New York); the actor George Frederick Cooke, as Richard III. (Pennsylvania Academy of the Fine Arts, Philadephia); Lafayette (Independence Hall); Thomas Jefferson (U.S. Military Academy, West Point, New York); Charles and Frances Anne Kemble, and Reverdy Johnson. His son ALFRED SULLY (1821–1879) an officer in the United States army, was a brigade-commander in the Army of the Potomac in 1862–63, and after 1863 commanded the department of Dakota and conducted several campaigns against hostile Indians in the north-west. In 1865 he was breveted brigadier-general in the regular army and major-general of volunteers.

SULLY-PRUDHOMME, RENE FRANÇOIS ARMAND PRUDHOMME (1839–1907), French poet, was born in Paris on the 16th of March 1839. He was educated at the Lycée Bonaparte, where after a time he took his degree as Bachelier ès Sciences. An attack of ophthalmia then interrupted his studies and necessitated an entire change in the course of his career. The scientific habit of mind, however, which he had derived from these years of technical study never left him; and it is in the combination of this scientific bent, with a soul aspiring towards what lies above and beyond science, and a conscience perpetually in agitation, that the striking originality of Sully-Prudhomme's character is to be found. He found employment for a time in the Schneider factory at Creuzot, but he soon abandoned an occupation to which he was eminently unsuited. He subsequently decided to read law, and entered a notary's office at Paris. It was during this period that he composed those early poems which were not long in acquiring celebrity among an ever-widening circle of friends. In 1865 he published his first volume of poems, which had for sub-title *Stances et poèmes*. This volume was favourably reviewed by Sainte-Beuve, to whose notice it had been brought by Gaston Paris. It was at this moment that the small circle of which Leconte de Lisle was the centre were preparing the *Parnasse*, to which Sully-Prudhomme contributed several pieces. In 1866 Lemerre published a new edition of the *Stances et poèmes* and a collection of sonnets entitled *Les Épreuves* (1866). From this time forward Sully-Prudhomme devoted his life entirely to poetry. It was in the volume of *Les Épreuves* that the note of melancholy which was to dominate through the whole work of his life was first clearly discernible. In 1869 he published a translation of the first book of Lucretius with a preface, and *Les Solitudes*. In 1870 a series of domestic bereavements and a serious paralytic illness resulting from the strain and fatigue of the winter of 1870, during which he served in the Garde Mobile, shattered his health. In 1872 he published *Les Écuries d'augias*, *Croquis italiens*, *Impressions de la guerre* (1866–72) and *Les Destins*, *La Révolte des heurs* in 1874, in 1875 *Les Vaines tendresses*, in 1878 *La Justice*, in 1886 *Le Prisme*, and in 1888 *Le Bonheur*. All these poems were collected and republished under the title of *Poésies*, occupying four volumes of his *Œuvres* (6 vols., 1883–1904). After the publication of *Le Bonheur* he practically ceased to produce verse, and devoted himself almost entirely to philosophy. He published two volumes of prose criticism *L'expression dans les beaux arts* (1884) and *Réflexions sur l'art des vers* (1892). Various monographs by him appeared from time to time in the philosophical reviews, and among them a remarkable series of essays (*Revue des deux mondes*, Oct. 15th, Nov. 15th, 1890) on Pascal, and a valuable study on the "Psychologie du libre arbitre" in the *Revue de métaphysique et de morale* (1906). He was elected to the Academy on the 8th of December 1881. On the 10th of December 1901 he was awarded the Nobel prize for literature, and devoted most of the money to the foundation of a prize for poetry to be awarded by the *Société de gens de lettres*. He was one of the earliest champions of Captain Dreyfus. In 1902 he wrote, in collaboration with Charles Richet, *Le Problème des causes finales*. During his later years he lived at Châtenay in great isolation, a victim of perpetual ill-health, and mainly occupied with his *Vraie religion selon Pascal* (1905). He had been partially paralysed for some time when he died suddenly on the 6th of September 1907. He left a volume of unpublished verse and a prose work, *Le Lien social*, which was a revision of an introduction which he had contributed to Michelet's *La Bible de l'humanité*.

What strikes the reader of Sully-Prudhomme's poetry first and foremost is the fact that he is a thinker; and moreover a poet who thinks, and not a thinker who turns to rhyme for recreation. The most strikingly original portion of his work is to be found in his philosophic and scientific poetry. If he has not the scientific genius of Pascal, he has at least the scientific habit of mind and a delight in mathematic certainties. In attempting to interpret the universe as science reveals it to us he has created a new form of poetry which is not lacking in a certain grandeur. One of his most beautiful poems, "L'Idéal" (*Stances et poèmes*), is inspired by the thought, which is due to scientific calculations, of stars so remote from our planet that their light has been on its way to us since thousands of centuries and will one day be visible to the eyes of a future generation. The second chief characteristic of Sully-Prudhomme's poetry is the extreme sensibility of soul, the profoundly melancholy note which we find in his love lyrics and his meditations. Sully-Prudhomme is above all things introspective; he penetrates into the hidden corners of his heart; he lays bare the subtle torments of his conscience, the shifting currents of his hopes and fears, belief and disbelief in face of the riddle of the universe to an extent so poignant as to be sometimes almost painful. And to render the fugitive phases and tremulous adventures of his spirit he finds incomparably delicate shades of expression, an exquisite and sensitive diction. We are struck in reading his poems by the nobility of his ideas, by a religious elevation like that of Pascal; for there is in his work something both of Lucretius and of Pascal. Yet he is far from being either an Epicurean or a Jansenist; he is rather a Stoic to whom the deceptions of life have brought pity instead of bitterness.

As an artist Sully-Prudhomme is remarkable for the entire absence of oratorical effect; for the extreme simplicity and fastidious precision of his diction. Other poets have been endowed with a more glowing imagination; his poetry is neither exuberant in colour nor rich in sonorous harmonies of rhyme. The grace of his verse is a grace of outline and not of colour, his melody one of subtle rhythm; his verse is as if carved in ivory, his music like that of a perfect unison of stringed instruments. His imagination is inseparable from his ideas, and this is the reason of the extraordinary perspicuity of his poetic style. He extends poetry to two extreme limits; on the one hand to the borderland of the unreal and the dreamlike, as in a poem such as "Le Rendezvous" (*Vaines tendresses*), in which he seems to express the inexpressible in precise language; on the other hand, in his scientific poems he encroaches on the province of prose. His poetry is plastic in the creation of forms which fittingly express his fugitive emotions and his elevated ideas. Both by the charm of his pure and perfect phrase, by his consummate art, and the dignity which informs all his work, Sully-Prudhomme deserves rank among the foremost of modern poets. (E. G.)

See C. Hémon, *La Philosophie de Sully-Prudhomme* (1907), *Sully-Prudhomme* by E. Zyromski (Paris 1907).

SULMONA, or SOLMONA (anc. *Sulmo*), a city and episcopal see of the Abruzzi, Italy, in the province of Aquila, 40 m. by rail S.E. by E. of that town, and 107 m. E. by N. of Rome (75 m. direct). Pop. (1901), 13,372 (town), 18,247 (commune). Sulmona is situated at a height of 1322 ft. above the sea on the Gizio, a tributary of the Pescara, which supplies water-power to its paper-mills, fulling-mills and copper-works. Its cathedral of San Panfilio has a 14th-century portal. The interior has been modernized, but in the crypt are some medieval sculptures.

Sulmona has also in S. Maria della Tomba a good example of pure Gothic. S. Francesco d'Assisi occupies the site of an older and larger church, the Romanesque portal of which still stands at the end of the Corso Ovidio, and forms the entrance to the meat market. Opposite is a picturesque aqueduct of 1266 with pointed arches. S. Agostino has a good Gothic portal. The Ospedale Civico, next to the church of the Annunziata, begun in the first half of the 15th century, shows an interesting mixture of Gothic and Renaissance styles. The window of the Palazzo Tabassi is similar, and both are due to Lombard masters. In the court of the grammar school is a fine 15th-century statue of Ovid, the most celebrated native of the town, whose memory is preserved among the peasants in songs and folk-lore. The Porta Napoli is an interesting gate of the early 14th century. Innocent VII. was a native of the town. In the vicinity of the town is Monte Morrone where Pietro di Morone lived (*c.* 1254) as a hermit and founded a monastery for his hermits, who after his elevation to the papacy as Celestine V. took the name of Celestines; the monastery (S. Spirito) remained till 1870, when it was transformed into a prison. There are some ruins of the imperial period, attributed, groundlessly, to the house of Ovid near it. The church contains a Gothic tomb of 1412 by a German master, in which Renaissance influence is, according to Burckhardt, traceable for the first time in south Italy in the realistic characterization of the portrait figures.

Sulmo, a city of the Paeligni, is first mentioned during the Second Punic War (211 B.C.). It was the second town of the Paeligni in importance, Corfinium coming first. It became a Roman colony probably in the reign of Augustus, and as a municipium it continued to flourish throughout the empire. It was situated 7 m. south-east of Corfinium on the road to Aesernia, and was famous for its ironsmiths. Hardly any remains of the ancient city exist above ground, owing to frequent earthquakes. A number of discoveries of tombs (both archaic and of the Roman period), &c., have however been made (cf. A. de Nino, in *Notizie degli Scavi*, passim). Charles V. erected it into a principality, which he bestowed on Charles Lannoy, who had captured Francis I. at the battle of Pavia. It ultimately passed to the Corno and Borghese families. The bishopric is known as that of Valva and Sulmona.

SULPHONAL, or acetone diethyl sulphone $(CH_3)_2C(SO_2C_2H_5)_2$, a valuable hypnotic prepared by condensing acetone with ethyl mercaptan in the presence of hydrochloric acid, the mercaptol $(CH_3)_2C(SC_2H_5)_2$ formed being subsequently oxidized by potassium permanganate (E. Baumann, *Ber.*, 1886, 19, p. 2808). It is also formed by the action of alcoholic potash and methyl iodide on ethylidene diethyl sulphine, $CH_3{\cdot}CH(SO_2C_2H_5)_2$ (which is formed by the oxidation of dithioacetal with potassium permanganate). It crystallizes in prisms melting at 125° C., which are practically insoluble in cold water, but dissolve in 15 parts of hot and also in alcohol and ether.

It is the *sulphonalum* of the B.P., and the *sulphomethanum* of the U.S.P. It produces lengthened sleep in functional nervous insomnia, and is also useful in insanity, being given with mucilage of acacia or in hot liquids, owing to its insolubility, or in large capsules. Its hypnotic power is not equal to that of chloral, but as it is not a depressant to the heart or respiration it can be used when morphine or chloral are contra-indicated. It is, however, very uncertain in its action, often failing to produce sleep when taken at bedtime, but producing drowsiness and sleep the following day. The drowsiness the next day following a medicinal dose can be avoided by a saline laxative the morning after its administration. It is unwise to use it continuously for more than a few days at a time, as it tends to produce the sulphonal habit, which is attended by marked toxic effects, disturbances of digestion, giddiness, staggering gait and even paralysis of the lower extremities. These effects are accompanied by skin eruptions, and the urine becomes of a dark red colour (haematoporphinuria). Sulphonal is cumulative in its effects. Many fatal cases of sulphonal poisoning are on record, both from chronic poisoning and from a single large dose. Trional $(CH_3)(C_2H_5)C(SO_2C_2H_5)_2$, and tetronal, $(C_2H_5)_2C(SO_2C_2H_5)_2$, are also hypnotics. They are faster in action than sulphonal, and trional does not disorder the digestion.

SULPHONIC ACIDS, in organic chemistry, a group of compounds of the type $R{\cdot}SO_3H$, where R is an alkyl or an aryl group.

Aliphatic Sulphonic Acids.—The members of this class may be prepared by the direct sulphonation of some paraffins (I. Worstall, *Amer. Chem. Journ.*, 1898, 20, p. 664); by the oxidation of mercaptans with concentrated nitric acid (H. Kopp, *Ann.*, 1840, 35, p. 346); in the form of their salts from the alkyl halides and alkaline sulphites, and as esters from the alkyl halides and silver sulphite. They are colourless oils or crystalline solids which are extremely hygroscopic, very soluble in water and have a strongly acid reaction. They are unaffected by heating with aqueous alkalis or acids and are stable towards concentrated nitric acid. Phosphorus pentachloride converts them into the corresponding acid chlorides, $R{\cdot}SO_2Cl$, which are decomposed slowly by water. These chlorides, on reduction by zinc and sulphuric acid, pass readily into the mercaptans, whilst if zinc dust and alcohol be used they are converted into the sulphinic acids, $R{\cdot}SO_2H$.

Methyl sulphonic acid, $CH_3{\cdot}SO_3H$, was obtained by H. Kolbe (*Ann.*, 1845, 54, p. 174) by reducing trichloromethyl sulphonic chloride (formed from chlorine and carbon bisulphide in the presence of water: $CS_2+5Cl_2+2H_2O=CCl_3{\cdot}SO_2Cl+4HCl+SCl_2$) with sodium amalgam. It is a colourless syrup which decomposes when heated above 130° C. The corresponding acid chloride is an extremely stable solid which melts at 135° C. It is formed by the action of carbon bisulphide on potassium bichromate in the presence of nitric and hydrochloric acids (Loew, *Zeit. f. Chem.*, 1869, p. 82). When heated under pressure it decomposes with the final production of carbonyl and thionyl chlorides: $CCl_3{\cdot}SO_2Cl=CCl_4+SO_2=COCl_2+SOCl_2$. *Ethyl sulphonic acid*, $C_2H_5{\cdot}SO_3H$, is a crystalline deliquescent solid formed by oxidizing ethyl mercaptan or by reducing vinyl sulphonic acid, $CH_2{:}CH{\cdot}SO_3H$ (Kohler, *Amer. Chem. Journ.*, 1898, 20, p. 687).

Thiosulphonic acids of the type $R{\cdot}SO_2{\cdot}SH$ are formed by the action of the sulphochlorides on a concentrated solution of potassium sulphide: $R{\cdot}SO_2Cl+K_2S=R{\cdot}SO_2K+S+KCl=KCl+R{\cdot}SO_2{\cdot}SK$; or by the action of the salt of a sulphinic acid on an alkaline sulphide in the presence of iodine (Otto, *Ber.*, 1891, 24, p. 144).

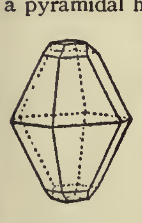
Aromatic Sulphonic Acids.—The acids of this group are very similar to the corresponding aliphatic sulphonic acids and are usually obtained by the direct heating of an aromatic hydrocarbon with concentrated sulphuric acid, fuming sulphuric acid or sulphur chlorhydrin. After the action is completed they may frequently be "salted out" by adding common salt to the acid solution until no more dissolves, when the sodium salt of the acid separates (L. Gattermann, *Ber.*, 1891, 24, p. 2121). They are also formed by oxidizing thiophenols or by decomposing diazonium salts with sulphurous acid. The free acids are usually hygroscopic, crystalline solids which are readily soluble in water. When heated under pressure with concentrated hydrochloric acid to about 150° C. they yield hydrocarbons and sulphuric acid. The salts usually crystallize well, and those of the alkali metals are employed in the preparation of phenols, into which they pass when fused with the caustic alkalis. When distilled with potassium cyanide they yield the aromatic nitriles. The sulphonic acids with phosphorus pentachloride are converted into sulphochlorides which are stable to cold water, but with ammonia they yield sulphonamides, $R{\cdot}SO_2NH_2$, and with alcohols esters of the sulphonic acids.

Benzene sulphonic acid, $C_6H_5{\cdot}SO_3H,1\frac{1}{2}H_2O$, crystallizes in small plates and is very deliquescent. *Benzene sulphochloride*, $C_6H_5{\cdot}SO_2Cl$, is a colourless fuming liquid which boils at 120° C. (10 mm.). The aminobenzene sulphonic acids, particularly the meta and para compounds, are of importance owing to their employment in the colour industry. The direct sulphonation of aniline yields the para acid, *sulphanilic acid*, $C_6H_4(NH_2)(SO_3H)$, which crystallizes in small plates and is sparingly soluble in cold water. When fused with caustic potash it yields aniline, whilst oxidation with chromic acid yields benzoquinone. In constitution it is probably to be regarded as a cyclic ammonium salt, $C_6H_4\left\langle\begin{array}{l}NH_3\\SO_3\end{array}\right\rangle$. When diazotized in acid solution and coupled with dimethyl aniline it yields helianthine, the sodium salt of which is used as an indicator (*q.v.*). *Metanilic acid* $C_6H_4(NH_2)(SO_3H)$ [1.3], which crystallizes in prisms, is formed by the reduction of meta-nitrobenzene sulphonic acid and is used in the preparation of various azo dyes.

Sulphinic acids, $R \cdot SO_2H$, are formed by reducing sulphochlorides with zinc dust; by the action of sulphur dioxide on the zinc aikyls (Hobson, *Ann*, 1857, 102, p. 72; 1858, 106, p. 287); by the action of sulphochlorides on mercaptans in alkaline solution; and by the action of the Grignard reagent on sulphur dioxide or thionyl chloride (Rosenheim, *Ber.*, 1904, 37, p. 2152; Oddo, *R. Accad. Lin.*, 1905 (5), 14 (i.), p. 169). The free acids are unstable. They are readily oxidized to sulphonic acids and reduced to mercaptans. Their alkali salts on treatment with the alkyl halides yield sulphones, R_2SO_2. Ethyl sulphinic acid, $C_2H_5 \cdot SO_2H$, is a colourless syrup. Benzene sulphinic acid, $C_6H_5 \cdot SO_2H$, crystallizes in large prisms and acts as a reducing agent. It decomposes when heated with water under pressure: $3C_6H_5 \cdot SO_2H = C_6H_5 \cdot SO_2H + C_6H_5 \cdot SO_2 \cdot S \cdot C_6H_5 + H_2O$. The potassium salt when fused with caustic potash yields benzene and potassium sulphite.

SULPHUR [symbol S, atomic weight 32·07 (O=16)], a non-metallic chemical element, known from very remote times and regarded by the alchemists, on account of its inflammable nature, as the principle of combustion; it is also known as brimstone (*q.v.*). The element occurs widely and abundantly distributed in nature both in the free state and in combination. Free or native sulphur, known also as "virgin sulphur," occurs in connexion with volcanoes and in certain stratified rocks in several modes, viz. as crystals, and as stalactitic, encrusting, reniform, massive, earthy and occasionally pulverulent forms as "sulphur meal." It seems rather doubtful whether the unstable monoclinic modification of sulphur (β–sulphur) is ever found in a native state.

The crystals belong to the orthorhombic system, and have usually a pyramidal habit (fig.), but may be sphenoidal or tabular. Twins are rare. The cleavage is imperfect, but there is a well-marked conchoidal fracture. The hardness ranges from about 1 to 2, and the sp.gr. from 1·9 to 2·1. Crystals of sulphur are transparent or translucent and highly refractive with strong birefringence; they have a resinous or slightly adamantine lustre, and present the characteristic sulphur-yellow colour. Impurities render the mineral grey, greenish or reddish, bituminous matter being often present in the massive varieties. Sulphur containing selenium, such as occurs in the isle of Vulcano in the Lipari Isles, may be orange-red; and a similar colour is seen in sulphur which contains arsenic sulphide, such as that from La Solfatara near Naples. The presence of tellurium in native sulphur is rare, but is known in certain specimens from Japan.



Volcanic sulphur usually occurs as a sublimate around or on the walls of the vents, and has probably been formed in many cases by the interaction of sulphur dioxide and hydrogen sulphide. Sublimed sulphur also results from the spontaneous combustion of coal seams containing pyrites. Deposits of sulphur are frequently formed by the decomposition of hydrogen sulphide, on exposure to the atmosphere: hence natural sulphureous waters, especially hot springs, readily deposit sulphur. The reduction of sulphates to sulphides by means of organic matter, probably through the agency of sulphur-bacteria, may also indirectly furnish sulphur, and hence it is frequently found in deposits of gypsum. Free sulphur may also result from the decomposition of pyrites, as in pyritic shales and lignites, or from the alteration of galena: thus crystals of sulphur occur, with anglesite, in cavities in galena at Monteponi near Iglesias in Sardinia; whilst the pyrites of Rio Tinto in Spain sometimes yield sulphur on weathering. It should be noted that the oxidation of sulphur itself by atmospheric influence may give rise to sulphuric acid, which in the presence of limestone will form gypsum: thus the sulphur-deposits of Sicily suffer alteration of this kind, and have their outcrop marked by a pale earthy gypseous rock called *briscale.*

Some of the most important deposits of sulphur in the world are worked in Sicily, chiefly in the provinces of Caltanisetta and Girgenti, as at Racalmuto and Cattolica; and to a less extent in the provinces of Catania, Palermo (Lercara) and Trapani (Gibellina). The sulphur occurs in Miocene marls and limestone, associated with gypsum, celestine, aragonite and calcite. It was formerly believed that the sulphur had a volcanic origin, but it is now generally held that it has either been reduced from gypsum by organic agencies, or more probably deposited from sulphur-bearing waters. Liquid occasionally enclosed in the sulphur and gypsum has been found by O. Silvestri and by C. A. H. Sjögren to contain salts like those of sulphur-springs. An important zone of sulphur-bearing Miocene rocks occurs on the east side of the Apennines, constituting a great part of the province of Forli and part of Pesaro, Cesena and Perticara are well-known localities in this district, the latter yielding crystals coated with asphalt. Sulphur is occasionally found crystallized in Carrara marble; and the mineral occurs also in Calabria. Fine crystals occur at Conil near Cadiz; whilst in the province of Teruel in Aragon, sulphur in a compact form replaces fresh-water shells and plant-remains, suggesting its origin from sulphur-springs. Nodular forms of sulphur occur in Miocene marls near Radoboj in Croatia, and near Swoszowic, south of Cracow. Russia possesses large deposits of sulphur in Daghestan in Transcaucasia, and in the Transcaspian steppes. Important deposits of sulphur are worked at several localities in Japan, especially at the Kosaka mine in the province of Rikuchiu, and at Yatsukoda-yama, in the province of Mutsu. Sulphur is worked in Chile and Peru. A complete list of localities for sulphur would include all the volcanic regions of the world. In the United States, sulphur occurs in the following states, in many of which the mineral has been worked: Louisiana (*q.v.*), Utah, Colorado, California, Nevada, Alaska, Idaho, Texas and Wyoming. The Rabbit Hole sulphur-mines are in Nevada, and a great deposit in Utah occurs at Cove Creek, Beaver county. In the British Islands native sulphur is only a mineralogical rarity, but it occurs in the Carboniferous Limestone of Oughterard in Co. Galway, Ireland.[1]

In combination the element chiefly occurs as metallic sulphides and sulphates. The former are of great commercial importance, being, in most cases, valuable ores, *e.g.* copper pyrites (copper), galena (lead), blende (zinc), cinnabar (mercury), &c. Of the sulphates we notice gypsum and anhydrite (calcium), barytes (barium) and kieserite (magnesium). Gaseous compounds, *e.g.* sulphur dioxide and sulphuretted hydrogen, are present in volcanic exhalations (see VOLCANO) and in many mineral waters. The element also occurs in the animal and vegetable kingdoms. It is present in hair and wool, and in albuminous bodies; and is also a constituent of certain vegetable oils, such as the oils of garlic and mustard. There is, in addition, a series of bacteria which decompose sulphureous compounds and utilize the element thus liberated in their protoplasm (see BACTERIOLOGY).

Extraction.—As quarried or mined free sulphur is always contaminated with limestone, gypsum, clay, &c.; the principle underlying its extraction from these impurities is one of simple liquation, *i.e.* the element is melted, either by the heat of its own combustion or other means, and runs off from the earthy residue.

In the simplest and crudest method, as practised in Sicily, a mass of the ore is placed in a hole in the ground and fired; after a time the heat melts a part of the sulphur which runs down to the bottom of the hole and is then ladled out. This exceptionally wasteful process, in which only one-third of the sulphur is recovered, has been improved by conducting the fusion in a sort of kiln. A semicircular or semi-elliptical pit (*calcarone*) about 33 ft. in diameter and 8 ft. deep is dug into the slope of a hill, and the sides are coated with a wall of stone. The sole consists of two halves slanting against each other, the line of intersection forming a descending gutter which runs to the outlet. This outlet having been closed by small stones and sulphate of lime cement, the pit is filled with sulphur ore, which is heaped up considerably beyond the edge of the pit and covered with a layer of burnt-out ore. In building up the heap a number of narrow vertical passages are left to afford a draught for the fire. The ore is kindled from above and the fire so regulated (by making or unmaking air-holes in the covering) that, by the heat produced

[1] *References.*—A very full article ("Zolfo") by G. Aichino, of the Geological Survey of Italy, will be found in the *Enciclopedia delle arte e industrie* (Turin, 1898). This includes a full bibliography. See also J. F. Kemp in Rothwell's *Mineral Industry* (1893), vol. ii.; Jules Brunfaut, *De l'Exploitation des soufres* (2nd ed., 1874); Georgio Spezia, *Sull' origine del solfo nei giacementi solfiferi della Sicilia* (Turin, 1892). For Japanese sulphur see T. Wada, *Minerals of Japan* (Tōkyō, 1904).

by the combustion of the least sufficient quantity of sulphur, the rest is liquefied. The molten sulphur accumulates on the sole, whence it is from time to time run out into a square stone receptacle, from which it is ladled into damp poplar-wood moulds and so brought into the shape of truncated cones weighing 110 to 130 lb each. These cakes are sent out into commerce. A calcarone with a capacity of 28,256 cub. ft. burns for about two months, and yields about 200 tons of sulphur. The yield is about 50%. The immense volumes of sulphurous acid evolved give rise to many complaints; all the minor pits suspend work during the summer to avoid destruction of the crops. A calcarone that is to be used all the year round must be at least 220 yds. from any inhabited place and 110 yds. from any field under cultivation.

More efficient is the Gill kiln which uses coke as a fuel. The kiln consists of two (or more) connected cells which are both charged with the ore. The first cell is heated and the products of combustion are led into the second cell where they give up part of their heat to the contained ore, so that by the time the first cell is exhausted the mass in the second cell is at a sufficiently high temperature to ignite spontaneously when air is admitted. Other methods have been employed, but with varying commercial success. For example, in the Gritti and Orlando processes the ore is charged into retorts and the fusion effected by superheated steam, the sulphur being run off as usual; or as was suggested by R. E. Bollman in 1867 the ore may be extracted by carbon bisulphide.

Crude sulphur, as obtained from kilns, contains about 3% of earthy impurities, and consequently needs refining. The following apparatus (invented originally by Michel of Marseilles and improved subsequently by others) enables the manufacturer to produce either of two forms of "refined" sulphur which commerce demands. It consists of a large stone chamber which communicates directly with two slightly slanting tubular retorts of iron. The retorts are charged with molten sulphur from an upper reservoir, which is kept at the requisite temperature by means of the lost heat of the retort fires. The chamber has a safety value at the top of its vault, which is so balanced that the least surplus pressure from within sends it up. The first puff of sulphur vapour which enters the chamber takes fire and converts the air of the chamber into a mixture of nitrogen and sulphur dioxide. The next following instalments of vapour, getting diffused throughout a large mass of relatively cold gas, condense into a kind of "snow," known in commerce and valued as "flowers of sulphur" (*flores sulphuris*). By conducting the distillation slowly, so that the temperature within the chamber remains at a sufficiently low degree, it is possible to obtain the whole of the product in the form of "flowers." If compact ("roll") sulphur is wanted the distillation is made to go on at the quickest admissible rate. The temperature of the interior of the chamber soon rises to more than the fusing-point of sulphur (113° C.), and the distillate accumulates at the bottom as a liquid, which is tapped off from time to time to be cast into the customary form of rods.

The Louisiana deposits are worked by a process devised by Herman Frasch in 1891. It consists in sinking a bore-hole, after the manner of a petroleum well, and letting in four pipes centrally arranged, the outer pipe being 10 in. in diameter, the next 6 in., the next 3 in. and the innermost 1 in. The operation consists in forcing down the 3-in. pipe superheated steam at 330° F. to melt the sulphur. Compressed air is now driven down the 1-in. pipe and bubbles into the melted sulphur and water; the specific gravity of which is greatly diminished, so that it rises to the surface through the outer pipes; it is then run off to settling tanks. The sulphur so obtained is 98% pure.

In some places sulphur is extracted from iron pyrites by one of two methods. The pyrites is subjected to dry distillation from out of iron or fire-clay tubular retorts at a bright red heat. One-third of the sulphur is volatilized—$3FeS_2 = Fe_3S_4 + 2S$—and obtained as a distillate. The second method is analogous to the calcarone method of liquation: the ore is placed in a limekiln-like furnace over a mass of kindled fuel to start a partial combustion of the mineral, and the process is so regulated that, by the heat generated, the unburnt part is decomposed with elimination of sulphur, which collects in the molten state on an inverted roof-shaped sole below the furnace and is thence conducted into a cistern. Such pyrites sulphur is usually contaminated with arsenic, and consequently is of less value than Sicilian sulphur, which is characteristically free from this impurity.

Large quantities are also recovered from alkali waste (see ALKALI MANUFACTURE); another source is the spent oxide of gas manufacture (see GAS).

The substance known as "milk of sulphur" (*lac sulphuris*) is very finely divided sulphur produced by the following, or some analogous, chemical process. One part of quicklime is slaked with 6 parts of water, and the paste produced diluted with 24 parts of water; 2·3 parts of flowers of sulphur are added; and the whole is boiled for about an hour or longer, when the sulphur dissolves. The mixed solution of polysulphides and thiosulphate of calcium thus produced is clarified, diluted largely, and then mixed with enough of pure dilute hydrochloric acid to produce a feebly alkaline mixture when sulphur is precipitated. The addition of more acid would produce an additional supply of sulphur (by the action of the $H_2S_2O_3$ on the dissolved H_2S); but this thiosulphate sulphur is yellow and compact, while the polysulphide part has the desired qualities, forming an extremely fine, almost white, powder. The precipitate is washed, collected, and dried at a very moderate heat.

Properties.—Sulphur exists in several allotropic modifications, but before considering these systematically we will deal with the properties of ordinary (or rhombic) sulphur. Commercial sulphur forms yellow crystals which melt at 113° and boil at 444·53° C. under ordinary pressure (H. L. Callendar, *Chem. News*, 1891, 63, p. 1); just above the boiling point the vapour is orange-yellow, but on continued heating it darkens, being deep red at 500°; at higher temperatures it lightens, becoming straw-yellow at 650°. These colour changes are connected with a dissociation of the molecules. At 524° Dumas deduced the structure S_6 from vapour-density determinations, whilst for the range 860° to 1040°, Sainte-Claire Deville and Troost deduced the formula S_2. Biltz (*Ber.*, 1888, 21, p. 2013; 1901, 34, p. 2490) showed that the vapour density decreased with the temperature, and also depended on the pressure. G. Preuner and W. Schupp (*Zeit. phys. Chem.*, 1909, 69, p. 157), in a study of the dissociation isotherms over 300°–850°, detected molecules of S_8, S_6 and S_2, whilst S_1 appears to exist below pressures of 30 mm. Boiling and freezing-point determinations of the molecular weight in solution indicate the formula S_8. The density of solid sulphur is 2·062 to 2·070, and the specific heat 0·1712; it is a bad conductor of electricity and becomes negatively electrified on friction. It ignites in air at 363° and in oxygen at 275–280° (H. Moissan, *Compt. rend.*, 1903, 137, p. 547), burning with a characteristic blue flame and forming much sulphur dioxide, recognized by its pungent odour. At the same time a little trioxide is formed, and, according to Hempel (*Ber.*, 1890, 23, p. 1455), half the sulphur is converted into this oxide if the combustion be carried out in oxygen at a pressure of 40 to 50 atmospheres. Sulphur also combines directly with most of the elements to form sulphides. The atomic weight was determined by Berzelius, Erdmann and Marchand, Dumas and Stas. Thomsen (*Zeit. phys. Chem.*, 1894, 13, p. 726) obtained the value 32·0606.

Allotropic Modifications.—Sulphur assumes crystalline, amorphous and (possibly) colloidal forms. Historically the most important are the rhombic (S_α) and monoclinic (S_β) forms, discussed by E. Mitscherlich in 1822 (see *Ann. chim. phys.*, 1823, 24, p. 264). The transformations of these two forms are discussed in CHEMISTRY: *Physical.* Rhombic sulphur may be obtained artificially by slowly crystallizing a solution of sulphur in carbon bisulphide, or, better, by exposing pyridine saturated with sulphuretted hydrogen to atmospheric oxidation (Ahrens, *Ber.*, 1890, 23, p. 2708). It is insoluble in water,[1] but readily soluble in carbon bisulphide, sulphur chloride and oil of turpentine. The common monoclinic variety is obtained by allowing a crust to form over molten sulphur by partially cooling it, and then breaking the crust and pouring off the still liquid portion, whereupon the interior of the vessel will be found coated with long needles of this variety. Like S_α it is soluble in carbon bisulphide. Three other monoclinic forms have been described. By acting upon a solution of sodium hyposulphite with potassium bisulphate, Gernez (*Compt. rend.*, 1884, 98, p. 144) obtained a form which he termed *nacré* (or pearly) sulphur; the same modification was obtained by Sabatier (ibid., 1885, 100, p. 1346) on shaking hydrogen persulphide with alcohol or ether. It is readily transformed into rhombic sulphur. Another form, mixed with the variety just described, is obtained by adding 3 to 4 volumes of alcohol to a solution of ammonium sulphide saturated with sulphur and exposing the mixture to air at about 5°. Engel's monoclinic form (*Compt. rend.*, 1891, 112, p. 866) is obtained by mixing a solution of sodium hyposulphite with double its volume of hydrochloric acid, filtering and extracting with chloroform; the extract yielding the variety on evaporation. A triclinic form is claimed to be obtained by Friedel (*Bull. soc. chim.*, 1879, 32, p. 14) on subliming ordinary sulphur.

[1] It is a common practice of keepers of dogs to place a piece of roll sulphur in the animal's water but this serves no useful purpose owing to this property.

Amorphous sulphur or S_γ exists in two forms, one soluble in carbon bisulphide, the other insoluble. Milk of sulphur (see above), obtained by decomposing a polysulphide with an acid, contains both forms. The insoluble variety may also be obtained by decomposing sulphur chloride with water and by other reactions. It gradually transforms itself into rhombic sulphur.

The colloidal sulphur, S_δ, described by Debus as a product of the interaction of sulphuretted hydrogen and sulphur dioxide in aqueous solution, is regarded by Spring (*Rec. trav. chim.*, 1906, 25, p. 253) as a hydrate of the formula $S_8 \cdot H_2O$. The "blue sulphur," described by Orloff, has been investigated by Paternò and Mazzucchelli (*Abs. Journ. Chem. Soc.*, 1907, ii. 451).

Molten Sulphur.—Several interesting phenomena are witnessed when sulphur is heated above its melting point. The solid melts to a pale yellow liquid which on continued heating gradually darkens and becomes more viscous, the maximum viscosity occurring at 180°, the product being dark red in colour. This change is associated with a change in the spectrum (N. Lockyer). On continuing the heating, the viscosity diminishes while the colour remains the same. If the viscous variety be rapidly cooled, or the more highly heated mass be poured into water, an elastic substance is obtained, termed plastic sulphur. This substance, however, on standing becomes brittle. The character of molten sulphur has been mainly elucidated by the researches of A. Smith and his collaborators. Smith (*Abs. Journ. Chem. Soc.*, 1907, ii. 20, 451, 757) regards molten sulphur as a mixture of two isomers S_λ and S_μ in dynamic equilibrium, S_λ being light in colour and mobile, and S_μ dark and viscous. At low temperatures S_λ predominates, but as the temperature is raised S_μ increases; the transformation, however, is retarded by some gases, *e.g.* sulphur dioxide and hydrochloric acid, and accelerated by others, *e.g.* ammonia. The solid derived from S_λ is crystalline and soluble in carbon bisulphide, that from S_μ is amorphous and insoluble. As to the formation of precipitated sulphur, Smith considers that the element first separates in the liquid S_μ condition, which is transformed into S_λ and finally into S_α; the insoluble (in carbon bisulphide) forms arise when little of the S_μ has been transformed; whilst the soluble consist mainly of S_α. Similar views are adopted by H. Erdmann (*Ann.*, 1908, 362, p. 133), but he regards S_μ as the polymer S_3, analogous to ozone O_3; Smith, however, regards S_μ as S_8.

Compounds.

Sulphuretted hydrogen, H_2S, a compound first examined by C. Scheele, may be obtained by heating sulphur in a current of hydrogen, combination taking place between 200° C. and 358° C., and being complete at the latter temperature, dissociation taking place above this temperature (M. Bodenstein, *Zeit. phys. Chem.*, 1899, 29, p. 315); by heating some metallic sulphides in a current of hydrogen; by the action of acids on various metallic sulphides (ferrous sulphide and dilute sulphuric acid being most generally employed); by the action of sulphur on heated paraffin wax or vaseline, or by heating a solution of magnesium sulphydrate. It is also produced during the putrefaction of organic substances containing sulphur and is found among the products obtained in the destructive distillation of coal. To obtain pure sulphuretted hydrogen the method generally adopted consists in decomposing precipitated antimony sulphide with concentrated hydrochloric acid. As an alternative, H. Moissan (*Comp. rend.*, 1903, 137, p. 363) condenses the gas by means of liquid air and fractionates the product.

Sulphuretted hydrogen is a colourless gas possessing an extremely offensive odour. It acts as a strong poison. It burns with a pale blue flame, forming sulphur dioxide and water. It is moderately soluble in water, the solution possessing a faintly acid reaction. This solution is not very stable, since on exposure to air it slowly oxidizes and becomes turbid owing to the gradual precipitation of sulphur. The gas is much more soluble in alcohol. It forms a hydrate of composition $H_2S \cdot 7H_2O$. (De Forcrand, *Compt. rend.*, 1888, 106, p. 1357.) The gas may be liquefied by a pressure of about 17 atmospheres, the liquid so obtained boiling at −61·8° C.; and by further cooling it yields a solid, the melting point of which is given by various observers as −82° to −86° C. (see Ladenburg, *Ber.*, 1900, 33, p. 637). It is decomposed by the halogens, with liberation of sulphur. Concentrated sulphuric acid also decomposes it: $H_2SO_4 + H_2S = 2H_2O + SO_2 + S$. It combines with many metals to form sulphides, and also decomposes many metallic salts with consequent production of sulphides, a property which renders it extremely useful in chemical analysis. It is frequently used as a reducing agent: in acid solutions it reduces ferric to ferrous salts, arsenates to arsenites, permanganates to manganous salts, &c., whilst in alkaline solution it converts many organic nitro compounds into the corresponding amino derivatives. Oxidizing agents rapidly attack sulphuretted hydrogen, the primary products of the reaction being water and sulphur.

By the action of dilute hydrochloric acid on metallic polysulphides, an oily product is obtained which C. L. Berthollet considered to be H_2S_5. L. Thénard, on the other hand, favoured the formula H_2S_2. It was also examined by W. Ramsay (*Journ. Chem. Soc.*, 1874, 12, p. 857). Hofmann, who obtained it by saturating an alcoholic solution of ammonium sulphide with sulphur and mixing the product with an alcoholic solution of strychnine, considered the resulting product to be H_2S_3; while P. Sabatier by fractionating the crude product in vacuo obtained an oil which boiled between 60° and 85° C. and possessed the composition H_4S_5.

Several halogen compounds of sulphur are known, the most stable of which is sulphur fluoride, SF_6, which was first prepared by H. Moissan and Lebeau (*Compt. rend.*, 1900, 130, p. 865) by fractionally distilling the product formed in the direct action of fluorine on sulphur. It is tasteless, colourless and odourless gas, which is exceedingly stable and inert. It may be condensed and yields a solid which melts at −55° C. Sulphuretted hydrogen decomposes it with formation of hydrofluoric acid and liberation of sulphur. Sulphur chloride, S_2Cl_2, is obtained as a by-product in the manufacture of carbon tetrachloride from carbon bisulphide and chlorine, and may also be prepared on the small scale by distilling sulphur in a chlorine gas, or by the action of sulphur on sulphuryl chloride in the presence of aluminium chloride (O. Ruff). It is an amber-coloured, fuming liquid possessing a very unpleasant irritating smell. It boils at 139° C. and is solid at −80° C. It is soluble in carbon bisulphide and in benzene. It is gradually decomposed by water: $2S_2Cl_2 + 3H_2O = 4HCl + 2S + H_2S_2O_3$, the thiosulphuric acid produced in the primary reaction gradually decomposing into water, sulphur and sulphur dioxide. Sulphur chloride dissolves sulphur with great readiness and is consequently used largely for vulcanizing rubber; it also dissolves chlorine. The chloride SCl_2 according to the investigations of O. Ruff and Fischer (*Ber.*, 1903, 36, p. 418) did not appear to exist, but E. Beckmann (*Zeit. phys. Chem.*, 1909, 42, p. 1839) obtained it by distilling the product of the interaction of chlorine and S_2Cl_2 at low pressures. The tetrachloride, SCl_4, is formed by saturating S_2Cl_2 with chlorine at −22° C. (Michaelis, *Ann.*, 1873, 170, p. 1). It is a yellowish-brown liquid which dissociates rapidly with rise of temperature. On cooling it solidifies to a crystalline mass which fuses at −80° C. (Ruff, ibid.). Water decomposes it violently with formation of hydrochloric and sulphurous acids. Sulphur bromide, S_2Br_2, is a dark red liquid which boils with decomposition at about 200° C. The products obtained by the action of iodine on sulphur are probably mixtures, although E. McIvor (*Chem. News*, 1902, 86, p. 5) obtained a substance of composition S_3I_2 (which in all probability is a chemical individual) as a reddish-coloured powder by the action of sulphuretted hydrogen on a solution of iodine trichloride.

Four oxides of sulphur are known, namely sulphur dioxide, SO_2, sulphur trioxide, SO_3, sulphur sesquioxide, S_2O_3, and persulphuric anhydride, S_2O_7. The dioxide has been known since the earliest times and is found as a naturally occurring product in the gaseous exhalations of volcanoes and in solution in some volcanic springs. It was first collected in the pure condition by J. Priestley in 1775 and its composition determined somewhat later by A. L. Lavoisier. It is formed when sulphur is burned in air or in oxygen, or when many metallic sulphides are roasted. It may also be obtained by heating carbon, sulphur and many metals with concentrated sulphuric acid: $C + 2H_2SO_4 = 2SO_2 + CO_2 + 2H_2O$; $S + 2H_2SO_4 = 3SO_2 + 2H_2O$; $Cu + 2H_2SO_4 = SO_2 + CuSO_4 + 2H_2O$; and by decomposing a sulphite, a thiosulphate or a thionic acid with a dilute mineral acid. It is a colourless gas which possesses a characteristic suffocating odour. It does not burn, neither does it support combustion. It is readily soluble in alcohol and in water, the solution in water possessing a strongly acid reaction. It is easily liquefied, the liquid boiling at −8° C., and it becomes crystalline at −72·7° C. (Walden, *Zeit. phys. Chem.*, 1902, 43, p. 432). Walden (ibid.) has shown that certain salts dissolve in liquid sulphur dioxide forming additive compounds, two of which have been prepared in the case of potassium iodide: a yellow crystalline solid of composition, $KI \cdot 14SO_2$, and a red solid of composition, $KI \cdot 4SO_2$. It is decomposed by the influence of strong light or when strongly heated. It combines directly with chlorine to form sulphuryl chloride and also with many metallic peroxides, converting them into sulphates. In the presence of water it frequently acts as a bleaching agent, the bleaching process in this case being one of reduction. It is frequently used as an "antichlor," since in presence of water it has the power of converting chlorine into hydrochloric acid: $SO_2 + Cl_2 + 2H_2O = 2HCl + H_2SO_4$. In many cases it acts as a reducing agent (when used in the presence of acids); thus, permanganates are reduced to manganous salts, iodates are reduced with liberation of iodine, &c., $2KMnO_4 + 5SO_2 + 2H_2O = K_2SO_4 + 2MnSO_4 + 2H_2SO_4$; $2KIO_3 + 5SO_2 + 4H_2O = I_2 + 2KHSO_4 + 3H_2SO_4$.

It is prepared on the industrial scale for the manufacture of sulphuric acid, for the preparation of sodium sulphate by the Hargreaves process, and for use as a bleaching-disinfecting agent and as a preservative. When compressed it is also used largely as a refrigerating agent, and in virtue of its property of neither burning nor supporting combustion it is also used as a fire extinctor. The solution of the gas in water is used under the name of sulphurous acid. The free acid has not been isolated, since on evaporation the solution gradually loses sulphur dioxide. This solution possesses reducing properties, and gradually oxidizes to sulphuric acid on exposure. When heated in a sealed tube to 180° C. it is transformed into sulphuric acid, with liberation of sulphur. Numerous salts, termed sulphites, are known. Since the free acid would be dibasic, two series of salts exist, namely, the neutral and acid salts. The neutral alkaline salts are soluble in water and show an alkaline reaction, the other neutral salts being either insoluble or difficultly soluble in water. The acid salts have a neutral or slightly acid reaction. The sulphites are prepared by the action of sulphur dioxide on the oxides, hydroxides or carbonates of the metals, or by processes of precipitation. Sulphurous acid may have either of the constitutions $O{:}S{<}^{OH}_{OH}$ or $^{O}_{O}{>}S{<}^{OH}_{H}$, or be an equilibrium mixture of these two substances. Although the correct formula for the acid is not known, sulphites are known of both types. Sodium sulphite is almost certainly of the second and unsymmetrical type. Two ethyl sulphites are known, the first or symmetrical form being derived from sulphuryl chloride and alcohol, and the second and unsymmetrical from sodium sulphite and ethyl iodide; the junction of one ethyl group with a sulphur atom in the second salt follows because it yields ethyl sulphonic acid, also obtainable from ethyl mercaptan, C_2H_5SH. Two isomeric sodium potassium sulphites are known, and may be obtained by neutralizing acid sodium sulphite with potassium carbonate, and acid potassium sulphite with sodium carbonate; their formulae are: $O_2SK(ONa)$ and $O_2SNa(OK)$.

There are various haloid derivatives of sulphurous acid. Thionyl fluoride, SOF_2, has been obtained as a fuming gas by decomposing arsenic fluoride with thionyl chloride (Moissan and Lebeau, *Compt. rend.*, 1900, 130, p. 1436). It is decomposed by water into hydrofluoric and sulphurous acids. Thionyl chloride, $SOCl_2$, may be obtained by the action of phosphorus pentachloride on sodium sulphite; by the action of sulphur trioxide on sulphur dichloride at 75–80° C. (*Journ. Chem. Soc.*, 1903, p. 420); and by the action of chlorine monoxide on sulphur at low temperature. It is a colourless, highly refracting liquid, boiling at 78°; it fumes on exposure to moist air. Water decomposes it into hydrochloric and sulphurous acids. On treatment with potassium bromide it yields thionyl bromide, $SOBr_2$, an orange-yellow liquid which boils at 68° C. (40 mm.) (Hartoz and Sims, *Chem. News*, 1893, 67, p. 82).

Sulphur trioxide, SO_3, mentioned by Basil Valentine in the 15th century, was obtained by N. Lemery in 1675 by distilling green vitriol. It may be prepared by distilling fuming sulphuric acid, or concentrated sulphuric acid over phosphorus pentoxide, or by the direct union of sulphur dioxide with oxygen in the presence of a catalyst, such as platinized asbestos (see SULPHURIC ACID). This oxide exists in two forms. The α- form is readily fusible and melts at 14·8° C. It corresponds to the simple molecular complex SO_3. The β- variety is infusible, but on heating to 50° C. is transformed into the α- form. It corresponds to the molecular complex $(SO_3)_2$. When perfectly dry this oxide has no caustic properties; it combines rapidly, however, with water to form sulphuric acid, with the development of much heat. It combines directly with concentrated sulphuric acid to form pyrosulphuric acid, $H_2S_2O_7$. It reacts most energetically with many organic compounds, removing the elements of water in many cases and leaving a carbonized mass. It combines directly with many elements and compounds and frequently acts as energetic oxidizing agent. It finds considerable application in the colour industry.

Sulphuryl fluoride, SO_2F_2, formed by the action of fluorine on sulphur dioxide (H. Moissan, *Compt. rend.* 132, p. 374), is an exceedingly stable colourless gas at ordinary temperatures, becoming solid at about −120° C. Sulphuryl chloride, SO_2Cl_2, first obtained in 1838 by Regnault (*Ann. chim. phys.*, 1838, (2), 69, p. 170), by the action of chlorine on a mixture of ethylene and sulphur dioxide, may also be obtained by the direct union of sulphur dioxide and chlorine (especially in the presence of a little camphor); and by heating chlorsulphonic acid in the presence of a catalyst, such as mercuric sulphate (Pawlewski, *Ber.*, 1897, 30, p. 765): $2SO_2Cl{\cdot}OH = SO_2Cl_2 + H_2SO_4$. It is a colourless fuming liquid which boils at 69° C. and which is readily decomposed by water into sulphuric and hydrochloric acids. Fluorsulphonic acid, $SO_2F{\cdot}OH$, is a mobile liquid obtained by the action of an excess of hydrofluoric acid on well-cooled sulphur trioxide. It boils at 162·6° and is decomposed violently by water. Chlorsulphonic acid, $SO_2Cl{\cdot}OH$, first prepared by A. Williamson (*Proc. Roy. Soc.*, 1856, 7, p. 11) by the direct union of sulphur trioxide with hydrochloric acid gas, may also be obtained by distilling concentrated sulphuric acid with phosphorus oxychloride: $2H_2SO_4 + POCl_3 = 2SO_2Cl{\cdot}OH + HCl + HPO_3$. It is a colourless fuming liquid which boils at 152–153° C. When heated under pressure it decomposes, forming sulphuric acid, sulphuryl chloride, &c. (Ruff, *Ber.*, 1901, 34, p. 3509). It is decomposed by water with explosive violence. Disulphuryl chloride, $S_2O_5Cl_2$, corresponding to pyrosulphuric acid, is obtained by the action of sulphur trioxide on sulphur dichloride, phosphorus oxychloride, sulphuryl chloride or dry sodium chloride: $6SO_3 + 2POCl_3 = P_2O_5 + 3S_2O_5Cl_2$; $S_2Cl_2 + 5SO_3 = S_2O_5Cl_2 + 5SO_2$; $SO_3 + SO_2Cl_2 = S_2O_5Cl_2$; $2NaCl + 3SO_3 = S_2O_5Cl_2 + Na_2SO_4$. It may also be obtained by distilling chlorsulphonic acid with phosphorus pentachloride: $2SO_2Cl{\cdot}OH + PCl_5 = S_2O_5Cl_2 + POCl_3 + 2HCl$. It is a colourless, oily, fuming liquid which is decomposed by water into sulphuric and hydrochloric acids. An oxychloride of composition $S_2O_3Cl_4$ has been described.

Sulphur sesquioxide, S_2O_3, is formed by adding well-dried flowers of sulphur to melted sulphur trioxide at about 12–15° C. The sulphur dissolves in the form of blue drops which sink in the liquid and finally solidify in blue-green crystalline crusts. It is unstable at ordinary temperatures and rapidly decomposes into its generators on warming. It is readily decomposed by water with formation of sulphurous, sulphuric and thiosulphuric acids, with simultaneous liberation of sulphur. Hyposulphurous acid, $H_2S_2O_4$, was first really obtained by Berthollet in 1789 when he showed that iron left in contact with an aqueous solution of sulphur dioxide dissolved without any evolution of gas, whilst C. F. Schönbein subsequently showed the solution possessed reducing properties. P. Schutzenberger (*Compt. rend.*, 1869, 69, p. 169) obtained the sodium salt by the action of zinc on a concentrated solution of sodium bisulphite: $Zn + 4NaHSO_3 = Na_2S_2O_4 + ZnSO_3 + Na_2SO_3 + 2H_2O$, the salt being separated from the sulphites formed by fractional precipitation. A solution of the free acid may be prepared by adding oxalic acid to the solution of the sodium salt. This solution is yellow in colour, and is very unstable decomposing at ordinary temperature into sulphur and sulphur dioxide. A pure zinc salt has been prepared by Nabl (*Monats.*, 1899, 20, p. 679) by acting with zinc on a solution of sulphur dioxide in absolute alcohol, whilst H. Moissan (*Compt. rend.*, 1902, 135, p. 647) has also obtained salts by the action of dry sulphur dioxide on various metallic hydrides. Considerable controversy arose as to the constitution of the salts of this acid, the formula of sodium salt, for example, being written as $NaHSO_2$ and $Na_2S_2O_4$; but the investigations of C. Bernthsen (*Ann.*, 1881, 208, p. 142; 1882, 211, p. 285; *Ber.*, 1900, 33, p. 126) seem to decide definitely in favour of the latter (see also T. S. Price, *Journ. Chem. Soc.*; also Bucherer and Schwalbe, *Zeit. angew. Chem.*, 1904, 17, p. 1447). Although this acid appears to be derived from an oxide S_2O_3, it is not certain that the known sesquioxide is its anhydride.

Persulphuric anhydride, S_2O_7, is a thick viscous liquid obtained by the action of the silent discharge upon a mixture of sulphur trioxide and oxygen. It solidifies at about 0° C. to a mass of long needles, and is very volatile. It is decomposed readily into sulphur trioxide and oxygen when heated. Water decomposes it with formation of sulphuric acid and oxygen: $2S_2O_7 + 4H_2O = 4H_2SO_4 + O_2$. Persulphuric acid, HSO_4, the acid corresponding to S_2O_7, has not been obtained in the free state, but its salts were first prepared in 1891 by H. Marshall (*Journ. Chem. Soc.*, 1891, p. 771) by electrolysing solutions of the alkaline bisulphates. The potassium salt, after recrystallization from warm water, separates in large tabular crystals. Its aqueous solution gradually decomposes with evolution of oxygen, behaves as a strong oxidant, and liberates iodine from potassium iodide. Solutions of persulphates in the cold give no precipitate with barium chloride, but when warmed barium sulphate is precipitated with simultaneous liberation of chlorine: $K_2S_2O_8 + BaCl_2 = BaSO_4 + K_2SO_4 + Cl_2$. The conductivity measurements of G. Bredig point to the salt possessing the double formula.

Thiosulphuric acid, formerly called hyposulphurous acid, $H_2S_2O_3$, cannot be preserved in the free state, since it gradually decomposes with evolution of sulphur dioxide and liberation of sulphur: $H_2S_2O_3 = S + SO_2 + H_2O$. The salts of the acid, however, are stable, the sodium salt in particular being largely used for photographic purposes under the name of "hypo." This salt may be prepared by digesting flowers of sulphur with sodium sulphite solution or by boiling sulphur with milk of lime. In this latter reaction the deep yellow solution obtained is exposed to air when the calcium polysulphide formed is gradually converted into thiosulphate by oxidation, and the calcium salt thus formed is converted into the sodium salt by sodium carbonate or sulphate. The thiosulphates are readily decomposed by mineral acids with liberation of sulphur dioxide and precipitation of sulphur: $Na_2S_2O_3 + 2HCl = 2NaCl + S + SO_2 + H_2O$. They form many double salts and give a dark violet coloration with ferric chloride solution, this colour, however, gradually disappearing on standing, sulphur being precipitated. The acid is considered to possess the structure $O_2S(SH)(OH)$, since sodium thiosulphate reacts with ethyl bromide to give sodium ethyl thiosulphate, which on treatment with barium chloride gives presumably barium ethyl thiosulphate. This salt, on standing, decomposes into barium dithionate, BaS_2O_6, and diethyl disulphide, $(C_2H_5)_2S_2$, which points to the presence of the SH group in the molecule.

The *thionic acids* are a group of sulphur-containing acids of general formula $H_2S_nO_6$, where $n = 2, 3, 4, 5$ and possibly 6. Dithionic acid, $H_2S_2O_6$, prepared by J. Gay-Lussac in 1819, is usually obtained in the form of its barium salt by suspending freshly precipitated hydrated manganese dioxide in water and passing sulphur dioxide into the mixture until all is dissolved; the barium salt is then precipitated by the careful addition of barium hydroxide. Much manganese sulphate is formed during the reaction, and H. C. Carpenter (*Journ. Chem. Soc.*, 1902, 81, p. 1) showed that this can be almost entirely avoided by replacing the manganese oxide by hydrated ferric oxide, the reaction proceeding according to the equation: $2Fe(OH)_3 + 3SO_2 = FeS_2O_6 + FeSO_3 + 3H_2O$. He points out that the available oxygen in the oxides may react either as $SO_2 + H_2O + O = H_2SO_4$ or as $2SO_2 + H_2O + O = H_2S_2O_6$; and that in the case of ferric oxide 96% of the theoretical yield of dithionate is obtained, whilst manganese oxide only gives about 75%. A solution of the free acid may be obtained by decomposing the barium salt with dilute sulphuric acid and concentrating the solution *in vacuo* until it attains a density of about 1·35 (approximately), further concentration leading to its decomposition into sulphur dioxide and sulphuric acid. The dithionates are all soluble in water and when boiled with hydrochloric acid decompose with evolution of sulphur dioxide and formation of a sulphate. Trithionic acid, $H_2S_3O_6$, is obtained in the form of its potassium salt by the action of sulphur dioxide on a solution of potassium thiosulphate: $2K_2S_2O_3 + 3SO_2 = 2K_2S_3O_6 + S$; or by warming a solution of silver potassium thiosulphate: $KAgS_2O_3 = Ag_2S + K_2S_3O_6$; whilst the sodium salt may be prepared by adding iodine to a mixture of sodium thiosulphate and sulphite: $Na_2SO_3 + Na_2S_2O_3 + I_2 = Na_2S_3O_6 + 2NaI$. The salts are unstable; and a solution of the free acid (obtained by the addition of hydrofluosilicic acid to the potassium salt) on concentration *in vacuo* decomposes rapidly: $H_2S_3O_6 = H_2SO_4 + S + SO_2$. Tetrathionic acid, $H_2S_4O_6$, is obtained in the form of its barium salt by digesting barium thiosulphate with iodine: $2Ba_2S_2O_3 + I_2 = BaS_4O_6 + 2BaI$, the barium iodide formed being removed by alcohol; or in the form of sodium salt by the action of iodine on sodium thiosulphate. The free acid is obtained (in dilute aqueous solution) by the addition of dilute sulphuric acid to an aqueous solution of the barium salt. It is only stable in dilute aqueous solution, for on concentration the acid decomposes with formation of sulphuric acid, sulphur dioxide and sulphur.

Wackenroder's solution (Debus, *Journ. Chem. Soc.*, 1888, 53, p. 278) is prepared by passing sulphuretted hydrogen gas into a nearly saturated aqueous solution of sulphur dioxide at about 0° C. The solution is then allowed to stand for 48 hours and the process repeated many times until the sulphur dioxide is all decomposed. The reactions taking place are complicated, and the solution contains ultimately small drops of sulphur in suspension, a colloidal sulphur (which Spring (*Rec. trav. chim.*, 1906, 25, p. 253) considers to be a hydrate of sulphur of composition $S_8{\cdot}H_2O$), sulphuric acid, traces of trithionic acid, tetra-and pentathionic acids and probably hexathionic acid. The solution obtained may be evaporated *in vacuo* until it attains a density of 1·46 when, if partially saturated with potassium hydroxide and filtered, it yields crystals of potassium pentathionate, $K_2S_5O_6{\cdot}3H_2O$. The formation of the pentathionic acid may be represented most simply as follows: $5SO_2 + 5H_2S = H_2S_5O_6 + 5S + 4H_2O$. The aqueous solution of the acid is fairly stable at ordinary temperatures. The pentathionates give a brown colour on the addition of ammoniacal solutions of silver nitrate and ultimately a black precipitate. Hexathionic acid, $H_2S_6O_6$, is probably present in the mother liquors from which potassium pentathionate is prepared. The solution on the addition of ammoniacal silver nitrate behaves similarly to that of potassium pentathionate, but differs from it in giving an immediate precipitate of sulphur with ammonia, whereas the solution of the pentathionate only gradually becomes turbid on standing.

The *per-acids* of sulphur were first obtained in 1898 by Caro (*Zeit. angew. Chem.*, 1898, p. 845) who prepared monopersulphuric acid by the action of sulphuric acid on a persulphate. This acid may also be prepared by the electrolysis of concentrated sulphuric acid, and it is distinguishable from persulphuric acid by the fact that it immediately liberates iodine from potassium iodide. It behaves as a strong oxidant and in aqueous solution is slowly hydrolysed. It most probably corresponds to the formula H_2SO_6.

Price, *Ber.*, 1902, 35, p. 291; *Journ. Chem. Soc.* (1906), p. 53; A. v. Baeyer and V. Villiger, *Ber.*, *passim.*

Pharmacology.—The sources of all sulphur preparations used in medicine (except calx sulphurata) are native virgin sulphur and the sulphides of metals. Those contained in the British Pharmacopoeia are the following: (1) *Sulphur sublimatum*, flowers of sulphur (U.S.P.), which is insoluble in water. From it are made (*a*) *confectio sulphuris*; (*b*) *unguentum sulphuris*; (*c*) *sulphur praecipitatum*, milk of sulphur (U.S.P.) which has a sub-preparation *trochiscus sulphuris* each lozenge containing 5 grs. of precipitated sulphur and 1 gr. of potassium acid tartrate; (*d*) *potassa sulphurata* (liver of sulphur), a mixture of salts of which the chief are sulphides of potassium; (*e*) *sulphuris iodidum* (U.S.P.), which has a preparation *unguentum sulphuris iodidi*, strength 1 in 25. From the heating of native calcium sulphate and carbon is obtained *calx sulphurata* (U.S. and B.P.), or sulphurated lime, a greyish-white powder.

Therapeutics.—Externally, sulphur is of use in skin affections. Powdered, it has little effect upon the skin, but in ointment or used by fumigation it has local therapeutic properties. In scabies (itch) it is the best remedy, killing the male parasite, which remains on the surface of the skin. To get at the female and the ova prolonged soaking in soap and water is necessary, the epiderm being rubbed away and the ointment then applied. Precipitated sulphur is also useful in the treatment of acne, but sulphurated lime is more powerful in acne pustulosa and in the appearance of crops of boils. Internally, sulphur is a mild laxative, being converted in the intestine into sulphides. Milk of sulphur, the confection and the lozenge, is used for this purpose. Sulphur and sulphur waters such as those of Harrogate, Aix-la-Chapelle and Aix-les-Bains, have a powerful effect in congested conditions of the liver and intestines, haemorrhoids, gout and gravel. Sulphur is of use in chronic bronchial affections, ridding the lungs of mucus and relieving cough. In chronic rheumatism sulphur waters taken internally and used as baths are effectual. Sulphur in some part escapes unchanged in the faeces.

When sulphur is burned in air or oxygen, sulphur dioxide is produced, which is a powerful disinfectant, used to fumigate rooms which have been occupied by persons suffering from some infectious disease.

SULPHURIC ACID, or Oil of Vitriol, H_2SO_4, perhaps the most important of all chemicals, both on account of the large quantities made in all industrial countries and of the multifarious uses to which it is put. It is not found in nature in the free state to any extent, and although enormous quantities of its salts, especially calcium and barium sulphate, are found in many localities, the free acid is never prepared from these salts, as it is more easily obtainable in another way, viz. by burning sulphur or a sulphide, and combining the sulphur dioxide thus formed with more oxygen (and water).

Originally prepared by heating alum, green vitriol and other sulphates, and condensing the products of distillation, sulphuric acid, or at least an impure substance containing more or less sulphur trioxide dissolved in water, received considerable attention at the hands of the alchemists. The acid so obtained from ferrous sulphate (green vitriol) fumes strongly in moist air, hence its name "fuming sulphuric acid"; another name for the same product is "Nordhausen sulphuric acid," on account of the long-continued practice of this process at Nordhausen.

Ordinary sulphuric acid, H_2SO_4, may be prepared by dissolving sulphur trioxide in water, a reaction accompanied by a great evolution of heat; by the gradual oxidation of an aqueous solution of sulphur dioxide, a fact which probably explains the frequent occurrence of sulphuric acid in the natural waters rising in volcanic districts; or by deflagrating a mixture of sulphur and nitre in large glass bells or jars, absorbing the vapours in water and concentrating the solution. The latter process, which was known to Basil Valentine, was commercially applied by the quack doctor, Joshua Ward (1685–1761), of Twickenham, England, to the manufacture of the acid, which was known as "oil of vitriol made by the bell" or *per campanum.* Dr John Roebuck (1718–1794), of Birmingham, replaced the glass vessels by leaden ones, thereby laying the foundation of the modern method of manufacture (see below).

Properties.—Pure sulphuric acid, H_2SO_4, is a colourless, odourless liquid of an oily consistency, and having a specific gravity of 1·8384 at 15°. It boils at 338°, and at about 400° the vapour dissociates into sulphur trioxide and water; at a red heat further decomposition ensues, the sulphur trioxide dissociating into the dioxide and water. It freezes to a colourless crystalline mass, melting at 10·5°. The acid is extremely hygroscopic, absorbing moisture from the atmosphere with great rapidity; hence it finds considerable application as a desiccating agent. The behaviour of aqueous solutions of sulphuric acid is very interesting. The pure acid (100% H_2SO_4) cannot be prepared by boiling down a weaker acid under any pressure (at least between 3 and 300 centimetres of mercury), an acid of the composition $H_2SO_4,\frac{1}{12}H_2O$ or $12SO_3,13H_2O$ being invariably obtained. Neither is there any advantage gained by mixing this hydrate with sulphur trioxide; for when such a mixture is concentrated by evaporation, sulphur trioxide is vaporized until the same hydrate is left. The pure acid, however, may be obtained by strongly cooling this hydrate.

when it separates in the form of white crystals, which melt at 10·5°, and on gentle heating evolve sulphur trioxide and again form the same hydrate. When strong sulphuric acid is mixed with water there is a great development of heat; the heat evolved when four parts of acid are mixed with one of water being sufficient to raise the temperature from 0° to 100° C. (Hence the laboratory precaution of always adding the acid to the water and not the water to the acid.) In addition to the heat evolution there is also a diminution in volume, the maximum occurring when the components are present in the ratio $H_2SO_4:2H_2O$, thus pointing to the existence of a hydrate $H_2SO_4,2H_2O$. A second hydrate, H_2SO_4,H_2O, may be obtained as rhombic crystals, which melt at 7° and boil at 205°, by diluting the strong acid until it has a specific gravity of 1·78, and cooling the mixture; this compound is sometimes known as *glacial sulphuric acid*. Both the mono- and di-hydrates form freeing mixtures with snow. Other hydrates have also been described.

Reactions.—Sulphuric acid has the widest commercial application of all chemical reagents. Here only reactions of commercial utility will be considered, and reference should be made to the article SULPHUR for reactions which are more of a purely scientific interest. In inorganic chemistry its principal applications are based on its solvent power for metals, and its power of expelling other acids from their salts. In the first group we have to notice the use of iron or zinc and dilute sulphuric acid for the manufacture of hydrogen, which may be used directly, as for inflating balloons or for purposes of combustion, or in the *nascent* condition, for reduction purposes, as generally is the case in organic chemistry (see ANILINE). It is worthy of notice that while many metals dissolve in cold dilute sulphuric acid, with the liberation of hydrogen, in accordance with the typical equation: $M + H_2SO_4 = MSO_4 + H_2$ (M denoting one atom of divalent or two atoms of a monovalent metal), there are several (copper, mercury, antimony, tin, lead and silver) which are insoluble in the cold dilute acid, but dissolve in the hot strong acid with evolution of sulphur dioxide, thus: $M + 2H_22SO_4 = MSO_4 + SO_2 + 2H_2O$. Carbon decomposes hot strong sulphuric acid on long continued boiling, with the formation of carbon dioxide and sulphur dioxide. The power which sulphuric acid exhibits for expelling other acids from their combinations, a power occasioned by its comparative involatility and high degree of avidity, forms the basis of a considerable number of commercial processes. Hydrochloric, hydrobromic, hydriodic, hydrofluoric, nitric, phosphoric and many other acids are manufactured by the action of sulphuric acid on their salts; the alkali and chlorine industries, and also the manufacture of bromine and iodine, employ immense quantities of this acid.

In organic chemistry sulphuric acid is extensively employed. Its powerful affinity for the elements of water makes it a valuable dehydrating and condensation agent. It extracts the elements of water from formic acid, giving carbon monoxide; from oxalic acid, giving a mixture of carbon monoxide and dioxide; from alcohol, to give ether or ethylene according to the conditions of the experiment; and from many oxygenated compounds (*e.g.* sugar, tartaric acid, &c.), with the production of charred masses. The formation of esters and ethers are generally facilitated by the presence of this acid. It also acts in an opposite manner in certain cases, *adding* the elements of water to compounds; thus, nitriles are converted into acid-amides, and various acetylene derivatives may be caused to yield ketonic derivatives. As an oxidizing agent its application is limited. The transformation of piperidine into pyridine by W. Königs, and the observation that anthraquinone yielded oxyanthraquinones when treated in the cold with strong sulphuric acid, and the recent introduction of fuming sulphuric acid for the oxidation of naphthalene to phthalic acid, a process of great value in the manufacture of artificial indigo, may be noted. But its chief technical application depends upon the formation of sulphonic acids when it reacts with aromatic hydrocarbon residues; these compounds being important either as a step towards the preparation of hydroxy-compounds, *e.g.* resorcin, the naphthols, alizarin, &c., or for preparing dye-stuffs in a more soluble form.

Sulphates.—Sulphuric acid, being a dibasic acid, forms two series of salts with monovalent metals: an acid sulphate, $MHSO_4$, and a normal sulphate, M_2SO_4. Acid sodium sulphate, $NaHSO_4$, has been employed in the manufacture of sulphur trioxide. When heated it loses water to form sodium pyrosulphate, $Na_2S_2O_7$, which on treatment with sulphuric acid yields normal sodium sulphate and sulphur trioxide. The normal sulphates are the more important, and occur widely and abundantly distributed in the mineral kingdom; anhydrite, gypsum, anglesite, barytes, celestite and kieserite are among the commonest species. As a general class, the sulphates are soluble in water, and exhibit well crystallized forms. Of the most insoluble we may notice the salts of the metals of the alkaline earths, barium, strontium and calcium, barium sulphate being practically insoluble, and calcium sulphate sparingly but quite appreciably soluble. Lead sulphate is very slightly soluble in water, soluble in strong sulphuric acid, and almost insoluble in alcohol.

Sulphates may be detected by heating the salt mixed with sodium carbonate on charcoal in the reducing flame of the blowpipe; sodium sulphide is thus formed, and may be identified by the black stain produced if the mass be transferred to a silver coin and then moistened. In solution, sulphates are always detected and estimated by the formation of a white precipitate of barium sulphate, insoluble in water and all the common reagents.

Manufacture.—The first step in its manufacture is the combustion of sulphur. Formerly this was employed exclusively in the free state as brimstone, and this is still the case to a considerable extent in some countries, notably in the United States, but the great bulk of sulphuric acid is now made from metallic sulphides, especially those of iron and zinc. Most of the brimstone of trade comes from Sicily, but in the United States Louisiana sulphur is playing an important part, and seems likely to oust the Sicilian sulphur. Free sulphur is also contained as "gas sulphur" in the "spent oxides" of gasworks, which are actually utilized for the manufacture of sulphuric acid. Sulphur is also recovered in a very pure state from the "alkali waste" of the Leblanc process, but this "recovered sulphur" is too expensive to be burned for the purpose in question. In the United Kingdom much gas sulphur is used for the manufacture of sulphuric acid, together with a limited quantity of Sicilian sulphur for the production of sulphuric acid free from arsenic.

A much larger percentage of the sulphuric acid is made from pyrites, *i.e.* more or less pure disulphide of iron which occurs in large quantities in many countries. Great Britain produces very little of it, Ireland a little more, but of poor quality. Most of the pyrites consumed in the United Kingdom come from Spain; this Spanish pyrites generally (not always) contains enough copper (say 3 or 4%) to make its extraction from the residues ("cinders") a paying process, and this of course cheapens the price of the sulphur to the acid manufacturer. Spain also supplies much pyrites to Germany, France and America, all of which countries are themselves producers of this ore. Sweden and Norway are exporters of it to all these countries. Good pyrites contains from 48 to 50%, exceptionally up to 52% of sulphur, of which all but from 1 to 4% is utilized when burning the ore. Another metallic sulphide, blende, ZnS, is of importance for Germany, Belgium and the United States, much less so for the United Kingdom, as a source of sulphur. Blende contains only about half as much sulphur as good pyrites, and this cannot be burned off as easily as from pyrites, but this "roasting" has to be done somehow in any case in order to prepare the ore for the extraction of the zinc.

Brimstone is easily burned without any extraneous help; indeed the only precaution required is to take care lest the heat produced by the burning sulphur should not volatilize part of it in the unburned state. This can never be entirely avoided, and sometimes causes trouble in the succeeding apparatus.

The roasting of pyrites always takes place without using any extraneous fuel, the heat given off by the oxidation of the sulphur and the iron being quite sufficient to carry on the process. If the ore is in pieces of the size of a walnut or upwards, it is roasted in plain "kilns" or "burners," provided with a grating of suitable construction for the removal of the cinders, with a side door in the upper part for charging in the fresh ore on the top of the partially burned ore, and with an arch-shaped roof, from which the burner-gas is carried away in a flue common to a whole set of kilns. The latter are always set in a row of twelve or more, and are one after another charged once or twice a day at appropriate intervals, so that a regular evolution of gas takes place all the day round. By employing suitable precautions, a gas of approximately uniform composition is obtained, containing from 6 to 8% sulphur dioxide, SO_2, with a little trioxide, SO_3, and about 12% of oxygen, which is more than sufficient for converting later all the SO_2 into SO_3 or H_2SO_4. The burning of "smalls" or "dust" was formerly considered much more difficult and incomplete than that of pieces, but this difficulty has been entirely overcome in various ways, principally by the "shelf-burner," originally constructed by E. Malétra, and mechanical burners, which were formerly almost entirely confined to America, where the saving of labour is a primary consideration. The first really successful mechanical pyrites-burner was constructed many years ago by MacDougall Bros. of Liverpool. The drawbacks still present in this burner caused it to be abandoned after a few years, but they have since been overcome by several recent inventors, principally American. The Hereshoff burner has been most widely introduced, both in America and in European countries. The roasting of blende is nothing like so easy as that of pyrites, since the heat developed by the oxidation of the zinc sulphide itself is not sufficient for carrying on the process, and external heat must be applied. It is now usually performed by a series of muffles, superposed one over another, so that the whole forms a kind of shelf-burner, with internally heated shelves (the "Rhenania" furnace). This operation is both more costly and more delicate than the roasting of pyrites, but it is now perfectly well understood, and gas is obtained from blende furnaces hardly inferior in quality to that yielded by pyrites kilns. In America, and quite exceptionally also in Europe, mechanical furnaces are used for the roasting of blende.

The gas produced in the burning of sulphur ores, when issuing from the burner, holds in mechanical suspension a considerable quantity of "flue-dust," which must be removed as far as is practicable before the gas is subjected to further treatment. Flue-dust contains principally ferric oxide, zinc oxide, arsenious and sulphuric acids, and small quantities of the various metals occurring in the raw ore. All the thallium and selenium on the market is obtained from this source. Sometimes the burner-gas is employed directly for the sake of the SO_2 which it contains, principally in the manufacture of "sulphite cellulose" from wood. When the gas is to be utilized for the manufacture of sulphuric acid the SO_2 must be combined with more oxygen, for which purpose an "oxygen carrier" must be employed. Until recently the only agent practically used for this purpose was furnished by the oxides of nitrogen; more recently other oxygen carriers, acting by "contact processes," have also come into use (see below).

The production of sulphuric acid by the assistance of the oxides of the nitrogen is carried out in the "vitriol chambers." These are immense receptacles, mostly from 100 to 200 ft. long, 20 to 30 ft. wide, and 15 to 25 ft. high, constructed of sheet-lead, the joints of the sheets being made by "burning" or autogenous soldering, *i.e.* fusing them together by a blow-pipe without the aid of solder (which would be quickly destroyed by the acid). The vitriol chambers must be supported on all sides by suitable wooden or iron framework, and they are always erected at a certain height over the ground, so that any leaks occurring can be easily detected. In nearly all cases several of these chambers are connected so as to form a set of a cubic capacity of from 100,000 to 200,000 cub. ft. The burner gas is introduced at one end, the waste gases issue from the other, the movement of the gases being impelled partly by their own chemical reactions, partly by the draught produced by a chimney (or tower), or by mechanical means. At the same time water is introduced in a number of places in the shape of steam or finely divided as a spray, to furnish the material for the reaction: $SO_2 + O + H_2O = H_2SO_4$. As this reaction of its own accord takes place only to a very small extent, an "oxygen carrier" is always introduced in the shape of the vapours of nitric acid or the lower oxides of nitrogen. By the play of reactions induced in this way practically the whole of the SO_2 is ultimately converted into sulphuric acid, and at the same time the nitrogen oxides are always recovered with comparatively very slight losses and made to serve over again.

The reactions taking place in the vitriol chambers are very complicated, and have been explained in many different ways. The view hitherto accepted by most chemists is that developed by G. Lunge, according to which there are two principal reactions succeeding each other, it may be in quite contiguous places, but under different conditions. Where the nitrous fumes prevail and there is less water present, sulphur dioxide combines with nitrous acid and oxygen to form nitroso-sulphuric acid, a crystalline substance of the formula $SO_2(OH)(ONO)$. The reaction is therefore: $SO_2 + O + HNO_2 = SO_5NH$. The solid substance is, however, only exceptionally met with, as it at once dissolves in the mist of sulphuric acid floating in the chamber and forms "nitrous vitriol." Wherever this nitrous vitriol comes into contact with liquid water (*not* steam), which is also present in the chamber in the shape of mist, and practically as dilute sulphuric acid, it is decomposed into sulphuric and nitrous acid, thus: $SO_2(OH)(ONO) + H_2O = H_2SO_4 + HNO_2$. The re-formed nitrous acid, although not stable, any more than is its anhydride, N_2O_3, is nevertheless the "oxygen carrier" in question, as the products of its spontaneous decomposition, when meeting with other compounds, always react like nitrous acid itself and thus may transfer an indefinite quantity of oxygen to the corresponding quantities of SO_2 and H_2O, with the corresponding formation of H_2SO_4. This theory at once explains, among other things, why the acid formed in the vitriol chambers always contains an excess of water (the second of the above-quoted reactions requiring the "mass action" of this excess), and why the external cooling produced by the contact of the chamber sides with the air is of great importance (*liquid* water in the shape of a mist of dilute sulphuric acid being necessary for the process).

In 1906 Lunge (in a paper published with Bert) to some extent modified his views, by introducing an intermediate compound, sulphonitronic acid, SO_5NH_2, which had been noticed by various chemists for some time through its property of imparting a deep blue colour to sulphuric acid. It is evident that the "nitrous gases" present in the vitriol chamber consist essentially of a mixture of NO and NO_2, the latter being formed from NO by the excess of oxygen present. The NO_2 (or NO + O) reacts upon $SO_2 + H_2O$, forming SO_3NH_2, which, being extremely unstable, is at once oxidized to SO_5NH (nitroso-sulphuric acid). The latter is now either converted by hydrolysis into sulphuric acid and nitrogen oxides: $2SO_5NH + H_2O = 2H_2SO_4 + NO + NO_2$, the latter acting as before: or it reacts with more SO_2, forming again sulphonitronic acid: $2SO_5NH + SO_2 + 2H_2O = H_2SO_4 + 2SO_5NH_2$. The latter can also split up directly into NO and SO_4H_2.

Whatever be the true theory of the vitriol-chamber process, there is no doubt about the way in which the reactions have to be carried out in practice. Since the reactions occur among gases and liquids in the nebulous state, vast spaces have to be provided in which the process may be carried out as completely as possible before the waste gases are allowed to escape into the outer air. These spaces cannot be constructed in any other way than is actually done in the shape of the lead chambers; neither iron nor brickwork can be employed for this purpose, as they would be quickly destroyed by the acid liquids and gases.

When issuing from the chambers, the gases still contain the whole of the free nitrogen contained in the air which had entered into the burners, together with about a third, or at least a fourth, of the oxygen originally present therein, such excess of oxygen being required in order to carry out the conversion of the sulphur dioxide into sulphuric acid as completely as possible. For similar reasons it is necessary to employ much more water than is required to form H_2SO_4; and this is all the more necessary as strong sulphuric acid dissolves the nitrous compounds in the shape of nitroso-sulphuric acid, and thus withdraws these oxygen carriers from the gas-space of the chambers where the necessary reactions take place. It follows from this that the acid collecting at the bottom of the chambers must never exceed a certain concentration, say 70%, H_2SO_4 having a specific gravity of 1·615, but it is preferable to make it only 66 to 67%, having a specific gravity of 1·57 to 1·58. On the other hand, it should never go down below 60% H_2SO_4, equivalent to a specific gravity of 1·50.

The commercial production of sulphuric acid imperatively requires that the nitrogen oxides (which originally were always introduced in the shape of nitric acid) should be available as long as possible, before being lost mechanically or by reduction to the inactive forms of nitrous oxide or elementary nitrogen. The first step towards securing this requirement was taken as early as 1827 by Gay-Lussac, who discovered that the nitrous fumes, otherwise carried away from the lead chambers by the waste atmospheric nitrogen and oxygen, could be retained by bringing the gases into contact with moderately strong sulphuric acid, the result being the formation of nitroso-sulphuric acid: $2H_2SO_4 + N_2O_3 = 2SO_2(OH)(ONO) + H_2O$, and the latter remaining dissolved in sulphuric acid as "nitrous vitriol." But this important invention was of little use until John Glover, about 1866, found that the nitrous vitriol could be most easily reintroduced into the process by subjecting it to the action of burner-gas before this enters into the lead chambers, preferably after diluting it with chamber acid, that is, acid of from 65 to 70%, H_2SO_4, as formed in the lead chambers. The reaction is then: $2SO_2(OH)(ONO) + SO_2 + 2H_2O = 3H_2SO_4 + 2NO$; that is to say, all the "nitre" is returned to the chambers in the shape of NO; the sulphuric acid employed in the Gay-Lussac process is not merely recovered, but an additional quantity is formed from fresh SO_2; as the heat of the burner-gases also comes into play, much water is evaporated, which supplies part of the steam required for the working of the chambers; and the acid issues from the apparatus in a "denitrated" and sufficiently concentrated state (78 to 80% H_2SO_4) to be used over again for absorbing nitrous vapours or any other purpose desired. Since that time, in every properly appointed sulphuric acid manufactory, the following cycle of operations is carried out. To begin with, in the burners pyrites (or, as the case may be, brimstone or blende) is made to yield hot burner-gas containing about 7% (in the case of brimstone 10 or 11%) of SO_2. This, after having been deprived of most of the flue-dust, is passed through the "Glover tower," *i.e.* an upright cylindrical or square tower, consisting of a leaden shell lined with heat- and acid-proof stone or brick, and loosely filled or "packed" with the same material, over which a mixture of acid from the Gay-Lussac tower and from the chambers trickles down in such proportions that it arrives at the bottom as denitrated acid of from 78 to 80% H_2SO_4. The gases now pass on to the lead chambers, described above, where they meet with more nitrous vapours, and with steam, or with water, converted into a fine dust or spray. Here the reactions sketched above take place, so that "chamber-acid" as already described is formed, while a mixture of gases escapes containing all the atmospheric nitrogen, some oxygen in excess, about 0·5% of the total SO_2, and some oxides of nitrogen. This gas is now passed through the Gay-Lussac tower, which somewhat resembles the Glover tower, but is usually filled with coke, over which sulphuric acid of about 80% H_2SO_4 trickles down in sufficient quantity to retain the nitrous vapours. Ultimately the waste gas is drawn off by a chimney, or sometimes by mechanical means.

Of course a great many special improvements have been made in the plant and the working of chamber systems; of these we mention only some of the most important. By judiciously watching all stages of the process, by observing the draught, the strength of the acid produced, the temperature, and especially by frequent analyses of the gases, the yield of acid has been brought up to 98% of the theoretical maximum, with a loss of nitre sometimes as low as two parts to 100 of sulphur burned. The supply of the nitric acid required to make up this loss is obtained in England by "potting" that is, by decomposing solid nitrate of soda by sulphuric acid in a flue between the pyrites burners and the chambers. On the continent of Europe makers generally prefer to employ liquid nitric acid, which is run through the Glover tower together with the nitrous vitriol. Although this method appears more troublesome, it allows the amount of nitre to be more easily and more accurately regulated. The size of the Glover towers, and more especially that of the Gay-Lussac towers, has been progressively increased, and thereby the cube of the lead chambers themselves has been diminished to a much greater extent. By improved

" packing " the towers have been rendered more durable, and in the case of the Gay-Lussac tower the loss of nitre has been diminished by avoiding the use of a coke packing, which acts upon that substance as a reducing agent. Many attempts have been made to reduce the chamber space by apparatus intended to bring about a better mixture of the gases, and to facilitate the interaction of the misty particles of nitrous vitriol and dilute acid floating in the chamber with each other and with the chamber atmosphere. The earliest really successful, and still the most generally applied apparatus of this kind, is the Lunge-Rohrmann " plate columns " or " reaction towers " placed between the chambers, but though this and similar apparatus has proved to be very useful in the later stages of the process, it has not been found practicable to do away with the lead chambers entirely. The pumping of the acids up to the top of the towers is now always performed by means of compressed air, either in the old " acid eggs," or more economically in " pulsometers."

Most of the sulphuric acid manufactured is not required to be of higher strength than is furnished by the vitriol chambers, either directly (65 to 70 %), or after a passage through the Glover tower (78 to 80 %). This, for instance, holds good of the acid employed in the manufacture of sulphate of soda and hydrochloric acid from common salt, and in the manufacture of superphosphates. But for many purposes more highly concentrated acid is required. Formerly all such acid was made by boiling down the dilute acid, for which purpose a great variety of apparatus was invented. The first question is always that of material. Lead can be used for the purpose only when the boiling-point of the acid is reduced by means of a vacuum—a plan which has not met with much success. Formerly glass vessels were generally employed and they still survive in England, but elsewhere they are not much used. Porcelain, enamelled iron, for high concentrations even cast-iron without any protection, are also in use. On the continent of Europe platinum vessels have been for a long time almost universal, and they have been greatly improved by an internal lining of gold. The second consideration is the form of the vessels; these may be open pans or dishes, or closed retorts, or combinations of both. We also note the Faure and Kessler apparatus, which consists of a platinum pan, surmounted by a double-walled leaden hood, in such a manner that, while the hood is constantly cooled from the outside by water, the thin acid condensing on its inside is carried away without being allowed to flow back into the pan. The majority of acid makers, however, prefer retorts made entirely of platinum, preferably provided by the Heraeus process with a dense, closely adherent coating of gold, including the top or " dome." The new Kessler furnace is a very ingenious apparatus, in which the fire from a gas-producer travels over the sulphuric acid contained in a trough made of Volvic lava, and surmounted by a number of perforated plates, over which fresh acid is constantly running down; the temperature is kept down by the production of a partial vacuum, which greatly promotes the volatilization of the water, whilst retarding that of the acid. This furnace is also very well adapted for impure acids, unsuitable for platinum or platinum-gold stills on account of the crusts forming at the bottom of the retorts; and it is more and more coming into use both in Great Britain and on the Continent. A third consideration is the condensation of the vapours formed in the concentrating process; the further the concentration proceeds the more sulphuric acid they contain. Condensation is a comparatively easy task in the case of platinum apparatus, but with glass or porcelain beakers or retorts it presents great difficulties. In this respect the Kessler furnace has also proved to be very efficacious, so that it is at the present time considered the best apparatus for the concentration of sulphuric acid found in the trade.

The highest strength of sulphuric acid practically attainable by boiling down is 98 % H_2SO_4, and this is only exceptionally reached, since it involves much expenditure of fuel, loss of acid and wear and tear of apparatus. The usual strength of the O.V. of commerce, mostly designated by its specific gravity as 168° Twaddell, is from 93 to 95, or at most 96 % H_2SO_4. When attempts are made to push the process beyond 98 % it is found that the acid which distils over is as strong as that which remains behind. Real " monohydrate " or acid approaching 100 % can be made by Lunge's process of cooling strong O.V. down to −16° C. when H_2SO_4 crystallizes out, or by the addition of anhydrous SO_3 in the shape of fuming acid.

Since the development of the contact processes the fuming acid has become so cheap that it is now exclusively used for the preparation of the acids approaching the composition of " monohydrate."

Fuming or Nordhausen Oil of Vitriol, a mixture or chemical compound of H_2SO_4, with more or less SO_3, has been made for centuries by exposing pyritic schist to the influence of atmospheric agents, collecting the solution of ferrous and ferric sulphate thus formed, boiling it down into a hard mass (" vitriolstein ") and heating this to a low red heat in small earthenware retorts. Since about 1800 this industry had been confined to the north-west of Bohemia, and it survived just till 1900, when it was entirely abandoned—not because its product had become any less necessary, but, quite on the contrary, because the enormously increasing demand for fuming sulphuric acid, arising through the discovery of artificial alizarine and other coal-tar colours, could not possibly be supplied by the clumsy Bohemian process. Other sources of supply had accordingly to be sought, and they were found by going back to a reaction known since the first quarter of the 19th century, when J. W. Döbereiner discovered the combination of SO_2 and O into SO_3 by means of spongy platinum. This reaction, now known by the name of the catalytic or contact process, was made the subject of a patent by Peregrine Phillips, in 1831, and was tried later in many ways, but had been always considered as useless for practical purposes until 1875, when it was simultaneously and independently taken up by Clemens Winkler in Freiberg, and by W. S. Squire and R. Messel in London. Both these inventors began in the same way, viz. by decomposing ordinary sulphuric acid by a high temperature into SO_2, O, and H_2O (the last of course being in the shape of steam), absorbing the water by sulphuric acid, and causing the SO_2 and O to combine to SO_3 by means of moderately heated platinum in a fine state of division. Winkler showed that this division was best obtained by soaking asbestos with a solution of platinum chloride and reducing the platinum to the metallic state, and he described later a specially active kind of " contact substance," prepared from platinum chloride at a low temperature. This revival of the synthetical production of SO_3, at a period when this article had suddenly become of great importance, caused the greatest excitement among chemists and led to numerous attempts in the same direction, some of which were at once sufficiently successful to compete with the Bohemian process. It was soon found that the production of a mixture of SO_2 and O from sulphuric acid, as above described, was both too troublesome and costly, and after a number of experiments in other directions inventors went back to the use of ordinary burner-gas from pyrites and sulphur burners. For a good many years the further development of this industry was surrounded by great mystery, but it is now known that a satisfactory solution of the difficulties existing in the above respect was attained in several places, for instance, at Freiberg and in London, by the labours of the original inventors, Professor Winkler and Dr Messel. These difficulties were mostly caused by the solid impurities contained in the burner-gases in the shape of flue-dust, especially the arsenic, which after a short time rendered the contact substance inactive, in a manner not as yet entirely understood. Another difficulty arose from the fact that the reaction $SO_2+O=SO_3$ is reversible, the opposite reaction, $SO_3=SO_2+O$ setting in but little above the temperature required for the synthesis of SO_3. As far as is known (so much secrecy having been observed), the best results obtained in various places, save one, did not exceed 67% of the theoretical quantity, the remaining 33% of SO_2 having to be converted into sulphuric acid in the ordinary lead chambers. As is now known, the exception (undoubtedly the only one until 1899) was the process discovered as early as 1889 by Dr R. T. J. Knietsch, of the Badische Anilin-und Soda-Fabrik, at Ludwigshafen, but kept strictly secret until 1899, when the patents were published. The principal features of this invention are, first, a much more thorough purification of the burner-gas than had been practised up to that time, both in a chemical and a mechanical sense, and second, the prevention of superheating of the contact substance, which formerly always occurred by the heat generated in the process itself. As the Badische process effects this prevention by cooling the contact apparatus by means of the gaseous mixture to be later submitted to the catalytic action, the mixture is at the time heated up to the requisite temperature, and a considerable saving of fuel is the consequence. Altogether this process has been brought to such a pitch of simplicity and perfection, that it is cheap enough, not merely for the manufacture of fuming oil of vitriol of all strengths, but even for that of ordinary sulphuric acid of chamber-acid strength, while it is decidedly cheaper than the old process in the case of stronger acids, otherwise obtained by concentration by fire. It should be noted that these are not the results of a few years' working with an experimental plant, but of many years' work with large plant, now equal to a capacity of 120,000 tons of pyrites per annum. It is therefore not too much to say that, in all probability, the contact process will ultimately be employed generally for concentrated acids. Still, for the reasons given in the beginning of this article, the revolution thus impending will require a certain time for its accomplishment. Since the Badische process has become known several other new contact processes have come into the field, in some of which ferric oxide is employed as contact substance, but we must refrain from describing these in detail. (G. L.)

Medicine.—Sulphuric acid or oil of vitriol is a colourless oily-looking liquid incompatible with alkalis and their carbonates, lead and calcium. There are two medicinal preparations: (1) *Acidum sulphuricum dilutum*, containing 13·65% of hydrogen sulphate, (2) *acidum sulphuricum aromaticum* (elixir of vitriol), containing alcohol, spirit of cinnamon and ginger and 13·8% of hydrogen sulphate.

Therapeutics—For external use, sulphuric acid is a powerful irritant and caustic, acting by its powerful affinity for water and therefore dehydrating the tissues and causing them to turn black. It coagulates the albumen. Strong sulphuric acid is occasionally used as a caustic to venereal sores, warts and malignant growths. It is difficult, however, to limit its action, and glacial acetic and nitric acids are preferable for this purpose. Considerable burns on the face or body may result from the application of sulphuric acid in the practice known as "vitriol-throwing," a brownish black eschar serving to distinguish the burns produced by this acid from those of other corrosive fluids. Internally, dilute sulphuric acid is used in poisoning by alkalis as a neutralizing agent. Both it and the aromatic solution are powerful intestinal astringents, and are therefore useful in diarrhoea of a serious type, being strongly recommended both as a prophylactic and as a treatment during epidemics of Asiatic cholera. Small doses of the aromatic acid also serve as a prophylactic to those artisans who work in lead and as a treatment in lead poisoning in order to form an insoluble sulphate of lead. Sponging the body with very dilute solutions of sulphuric acid is useful to diminish the night-sweats of phthisis.

Toxicology.—Given in toxic doses or in strong solution, sulphuric acid is a severe gastro-intestinal irritant, causing intense burning pain, extending from the mouth to the stomach, and vomiting of mucous and coffee-coloured material. The effects of the ingestion of large quantities may be so rapid that death may take place in a couple of hours, owing to collapse, consequent on perforation of the walls of the oesophagus or stomach, or from asphyxia due to swelling of the glottis consequent on some of the acid having entered the larynx. Should the patient survive the first twenty-four hours death generally results later from stricture of the oesophagus or intestine, from destruction of the glands of the stomach or from exhaustion. Death has occurred in a child from the ingestion of half a teaspoonful of the strong acid, but recovery is recorded after half an ounce had been swallowed. The treatment consists in the prompt neutralization of the acid, by chalk, magnesia, whiting, plaster, soap or any alkaline substance at hand; emetics or the stomach pump should not be used. Morphine may be given hypodermically to mitigate the pain. Should the patient survive he will probably have to be fed by rectal enemata. The prognosis of sulphuric acid poisoning is bad, 60 to 70% of the cases proving fatal. The post-mortem appearances will be those of corrosive poisoning. The buccal mucous membrane will be greyish, brown or black in colour, due to the corrosive effects of the acid.

SULPICIA, the name of two Roman poets. The earlier lived in the reign of Augustus, and was a niece of Messalla, the patron of literature. Her verses, which were preserved with those of Tibullus and were for long attributed to him, are elegiac poems addressed to a lover called Cerinthus, possibly the Cornutus addressed by Tibullus in two of his *Elegies* (bk. ii., 2 and 3; see Schanz, *Gesch. d. röm. Litt.* § 284; F. Plessis, *La Poésie latine*, pp. 376–377 and references there given). The younger Sulpicia lived during the reign of Domitian. She is praised by Martial (x. 35, 38), who compares her to Sappho, as a model of wifely devotion, and wrote a volume of poems, describing with considerable freedom of language the methods adopted to retain her husband Calenus's affection. An extant poem (70 hexameters) also bears her name. It is in the form of a dialogue between Sulpicia and the muse Calliope, and is chiefly a protest against the banishment of the philosophers by the edict of Domitian (A.D. 94), as likely to throw Rome back into a state of barbarism. At the same time Sulpicia expresses the hope that no harm will befall Calenus. The muse reassures her, and prophesies the downfall of the tyrant. It is now generally agreed that the poem (the MS. of which was discovered in the monastery of Bobbio in 1493, but has long been lost) is not by Sulpicia, but is of much later date, probably the 5th century; according to some it is a 15th-century production, and not identical with the Bobbio poem.

There are English translations by L. Evans in Bohn's *Classical Library* (prose, with Juvenal and Persius) and by J. Grainger (verse, 1759).

SULPICIUS RUFUS, PUBLIUS (*c.* 121–88 B.C.), Roman orator and statesman, legate in 89 to Cn. Pompeius Strabo in the Social War, and in 88 tribune of the plebs. Soon afterwards Sulpicius, hitherto an aristocrat, declared in favour of Marius and the popular party. He was deeply in debt, and it seems that Marius had promised him financial assistance in the event of his being appointed to the command in the Mithradatic War. To secure the appointment for Marius, Sulpicius brought in a franchise bill by which the newly enfranchised Italian allies and freedmen would have swamped the old electors (see further ROME, *History*, II. "The Republic"). The majority of the senate were strongly opposed to the proposals; a *justitium* (cessation of public business) was proclaimed by the consuls, but Marius and Sulpicius got up a riot, and the consuls, in fear of their lives, withdrew the *justitium*. The proposals of Sulpicius became law, and, with the assistance of the new voters, the command was bestowed upon Marius, then a mere *privatus*. Sulla, who was then at Nola, immediately marched upon Rome. Marius and Sulpicius, unable to resist him, fled from the city. Marius managed to escape to Africa, but Sulpicius was discovered in a villa at Laurentum and put to death; his head was sent to Sulla and exposed in the forum. Sulpicius appears to have been originally a moderate reformer, who by force of circumstances became one of the leaders of a democratic revolt. Although he had impeached the turbulent tribune C. Norbanus (*q.v.*), and resisted the proposal to repeal judicial sentences by popular decree, he did not hesitate to incur the displeasure of the Julian family by opposing the candidature for the consulship of C. Julius Caesar (Strabo Vopiscus), who had never been praetor and was consequently ineligible. His franchise proposals, as far as the Italians were concerned, were a necessary measure of justice; but they had been carried by violence. Of Sulpicius as an orator, Cicero says (*Brutus*, 55): "He was by far the most dignified of all the orators I have heard, and, so to speak, the most tragic; his voice was loud, but at the same time sweet and clear; his gestures were full of grace; his language was rapid and voluble, but not redundant or diffuse; he tried to imitate Crassus, but lacked his charm." Sulpicius left no written speeches, those that bore his name being written by a certain P. Canutius (or Cannutius). He is one of the interlocutors in Cicero's *De oratore*.

See Appian, *Bell. civ.* i. 55–60; Plutarch, *Sulla* and *Marius*; Vell. Pat. ii. 18; Livy, *Epit.* 77; E. A. Ahrens, *Die drei Volkstribunen* (Leipzig, 1836); Mommsen, *Hist. of Rome*, bk. iv. ch. 7; Long, *Decline of the Roman Republic*, vol. ii. ch. 17.

SULPICIUS RUFUS, SERVIUS (*c.* 106–43 B.C.), surnamed *Lemonia* from the tribe to which he belonged, Roman orator and jurist. He studied rhetoric with Cicero, and accompanied him to Rhodes in 78 B.C. Finding that he would never be able to rival his teacher he gave up rhetoric for law (Cic. *Brut.* 41). In 63 he was a candidate for the consulship, but was defeated by L. Licinius Murena (*q.v.*), whom he subsequently accused of bribery; in 51 he was successful. In the Civil War, after considerable hesitation, he threw in his lot with Caesar, who made him proconsul of Achaea in 46. He died in 43 while on a mission from the senate to Antony at Mutina. He was accorded a public funeral, and a statue was erected to his memory in front of the Rostra. Two excellent specimens of Sulpicius's style are preserved in Cicero (*Ad. Fam.* iv. 5 and 12). Quintilian (*Instit.* x. 1, 116) speaks of three orations by Sulpicius as still in existence; one of these was the speech against Murena, another *Pro* or *Contra Aufidium*, of whom nothing is known. He is also said to have been a writer of erotic poems. It is as a jurist, however, that Sulpicius was chiefly distinguished. He left behind him a large number of treatises, and he is often quoted in the Digest, although direct extracts are not found (for titles see Teuffel-Schwabe, *Hist. of Roman Lit.* 174, 4). His chief characteristics were lucidity, an intimate acquaintance with the principles of civil and natural law, and an unrivalled power of expression.

See R. Schneider, *De Servio Sulpicio Rufo* (Leipzig, 1834); O. Karlowa, *Römische Rechtsgeschichte*, vol. i. (Leipzig, 1885); the chief ancient authority is Cicero.

SULTAN (an Arabic word meaning "victorious" or "a ruler," *sultat*, dominion), a title of honour borne by a great variety of rulers of very varying powers and importance in Mahommedan Africa and the East. The word has thus no exact equivalent in English, and was early imported into the language in the Middle English form of *soudan* (from old Fr. *soudan*, *souldan*). This title is that conventionally applied by foreigners to the ruler of the Ottoman Empire, the sultan *par excellence*, whose proper styles are, however, *padishah* (emperor) and "commander of the faithful" (see AMIR). The feminine form "sultana" is derived from the Italian (fem. of *sultano*).

SULTANPUR, a town and district of British India, in the Fyzabad division of the United Provinces. The town is on the right bank of the river Gumti, midway between Benares and Lucknow, on the Oudh & Rohilkhand railway. Pop. (1901), 9550.

The DISTRICT OF SULTANPUR has an area of 1713 sq. m. The surface is generally level, being broken only by ravines in the neighbourhood of the rivers. The central portion is highly cultivated, while in the south are widespread arid plains and swampy *jhils* or marshes. The principal river is the Gumti, which passes through the centre of the district and affords a valuable highway for commerce. Minor streams are the Kandu, Pili, Tengha and Nandhia, the last two being of some importance, as their channels form the outlet for the superfluous water of the *jhils*, draining into the Sai. There are no forests in the district, only stunted *dhâk* jungles used for fuel. In 1901 the population was 1,083,904, showing an increase of less than 1% in the decade. Sultanpur is a purely agricultural district with a very dense population. The principal crops are rice, pulses, wheat, barley, sugar-cane and a little poppy. The main line of the Oudh & Rohilkhand railway from Lucknow to Rae Bareli and Mogul Serai serves the south-western portion.

The only incident worthy of note in the history of the district since the British annexation of Oudh is the revolt of the native troops stationed at Sultanpur during the Mutiny. The troops rose in rebellion on the 9th of June 1857, and, after murdering two of their officers, sacked the station. Upon the restoration of order Sultanpur cantonment was strengthened by a detachment of British troops; but in 1861 it was entirely abandoned as a military station.

See *Sultanpur District Gazetteer* (Allahabad, 1903).

SUMACH. The Sumach of commerce is the finely ground leaves of *Rhus coriaria*, a native of the North Mediterranean region from Portugal to Asia Minor; it is a shrub or low tree with hairy leaves composed of 11 to 15 elliptical leaflets with large blunt teeth, and large loose panicles of whitish-green flowers. Another species, *Rhus cotinus*, known as Venetian Sumach,

Sumach, *Rhus coriaria*. (½ nat. size.)
1. Flower (1½ nat. size). 2. Cluster of fruit. 3. One fruit. 4. A seed. (2, 3, 4, ½ nat. size.)

also a native of southern Europe and Asia Minor, yields the yellow dye-wood known as young fustic; it is also known as the Smoke-plant or Wig-tree, from the feathery or hairy appearance of the flower-stalks, which become elongated and hairy after the flowering. The genus *Rhus* is a member of the natural order Anacardiaceae and contains about 120 species of trees or shrubs mostly native in the temperature regions of both hemispheres. The leaves are alternate and simple or compound, with few to many entire-margined or serrated leaflets, and terminal or axillary panicles of small flowers with parts in fours or sixes. The species are mostly poisonous, some being especially noxious. Such are *Rhus toxicodendron*, the North American poison ivy, a shrub climbing on rocks and trees by means of rootlets, and poisonous to the touch. *R. venenata*, the North American poison elder sumach or dogwood, also contains an extremely irritant poison. *R. vermicifera* is the Japan lacquer or varnish-tree. Several species are cultivated in the British Isles as store, greenhouse or hardy trees.

SUMATRA, the westernmost and, next to Borneo, the largest of the Great Sunda Islands in the Malay Archipelago. It stretches N.W. to S.E. from Malacca Passage to Sunda Strait, between 5° 40′ N. and 5° 59′ S., and 95° 16′ and 106° 3′ 45″ E. Its length is about 1100 m., its extreme breadth 250 m., and its area, including the neighbouring islands, except Banka and Billiton, is 178,338 sq. m. The northern half runs roughly parallel to the Malay Peninsula, from which it is separated by the Strait of Malacca, and the southern end is separated by the narrow Sunda Strait from Java. Unlike Java, Sumatra has a series of considerable islands (Nias Islands, Mentawi Islands, &c.) arranged like outworks in front of the west coast, which faces the open Indian Ocean. The general physical features of the island are simple: a chain of lofty mountain ranges extends throughout its length, the western slopes descending rapidly towards the ocean and the eastern looking out over a vast alluvial tract of unusual uniformity.

Towards the north end of the island the spurs of the main chain sometimes extend towards the neighbourhood of the east coast and the eastern plain widens from north to south. Owing to this configuration of the island the watercourses of the western

Emery Walker sc.

side are comparatively short: only very few of them are large enough to be navigable. Those of the eastern slope, on the other hand, such as the Musi, Jambi, Indragiri, Kampar, Siak, Rokan, Panei, Bila and Asahan, are longer, and with many of their affluents are navigable in their middle and lower courses over considerable stretches for craft drawing 6 to 10 ft. The Musi and Jambi are navigable for 372 and 497 m. respectively. As waterways all the rivers labour under the drawbacks of rapids, mud-banks at their mouths, banks overgrown with forest, sparse population, and currents liable to serious variations due to irregularity of supply from the mountains and sudden rainfalls. In their lower courses some of them form enormous intercommunicating deltas. The mountainous regions contain numerous lakes, many evidently occupying the craters of extinct volcanoes. When, as sometimes happens, two or three of these craters have merged into one, the lake attains a great size. Among the larger lakes may be mentioned Toba; Maninyu, west of Fort de Kock; Singkara, south-east of Fort de Kock; Korinchi, inland from Indrapura; and Ranua, in the south-west.

Orography.—In order to appreciate the orography of the island the following sections of Sumatra should be discriminated one from another: (1) The valley of the Achin or Atjeh River. (2) The plains around the lake of Toba, which are of varied level and physical character. Those on the south and north lie at an elevation of 4000 ft., having the character of steppes, with scanty forest-cover, and, save in the narrow valleys and river-courses, are suitable for cattle-rearing. The plains on the east and west lie at a lower level and are eroded by larger rivers, clothed with forest, showing more sawahs and ladangs, or dry ricefields, and, near the rivers, planted with jagong (maize), coffee and fruits. Except on the south-east, where the Asahan flows away to the east coast, Toba Lake is surrounded by steep shores. According to R. D. M. Verbeek, P. van Dyk, B. Hagen and W. Volz, the lake had its origin in the collapse of a volcano. (3) The valley of the Batang Toru, with the plateau of Sipirok in the east and the mountain chain of Tapanuli in the west. On the south and south-east the valley is bounded by two volcanoes, Lubuk Raja and Si Buwal Buwali, whence were derived the volcanic tuffs of the valley and of the plateau of Sipirok, with their lakes, which are drained by the Batang Toru and its affluents. The valley varies in breadth from 5½ m. to half a mile and less. Flowing in a deep bed cut in the tuff strata, the river is not navigable. (4) The longitudinal valley of the Batang Gadis, with its affluent the Angkola, and in the south the valley of the Sumpur, the upper course of the Rokan, between Lubuk Raja in the north and Mt Merapi in the south. This valley is 64 m. long, with a mean breadth of 4 to 5 m. All the rivers of this valley, flowing in deep beds of eroded diluvial tuffs, with a fall as much sometimes as 330 to 660 ft. a mile, are unnavigable. The valley is bounded east and west by chains of slate and Palaeozoic rocks. The bottom is in many parts the diluvium of lakes drained by the rivers. (5) The section of middle Sumatra between the line of the three volcanoes, Singalang-Tandikat, Merapi and Sago on the north, and that of the three mountains Patah Sembilan, Korinchi and Tujuh on the south. This section is divided by the Middengebergte or middle chain into a northern half watered by the Ombilin or upper Indragiri with its affluents, and a southern half traversed by the Batang Hari or upper Jambi. To the north of the volcanoes, which rise to 9500 ft. or more, there is a high plateau of volcanic formation, whose elevation declines in a direction from west to east from 2950 to 1640 ft., with the lake of Maninyu (about 40 sq. m. in area) filling the hollow of an old volcano, and with rivers which have eroded their beds in the tuffs to a depth of 300 ft. and more. South of the volcanoes the northern affluents of the Ombilin—Sumpur, Sello and Sinamar—flow through valleys parallel to one another in a north-west to south-east direction. Here, too, are found fertile tuffs, and the valleys are densely populated. The rivers, like those already characterized, and for the same reason, are not available as waterways. Singkara Lake (44 sq. m.) is of origin similar to that of Maninyu. The Ombilin, issuing out of the lake on the east side and flowing through a plateau of Eocene sandstone, has on its banks the coalfields of Sungei Durian, &c., but is not serviceable as a waterway for that part of Sumatra. The coal has to be transported by railway via Solok to Padang (Emmahaven), a seaport on the west coast. Solok lies on the Sumami, which, flowing from the south to the lake of Singkara, prolongs the valley of the Sumpur to the Middengebergte. Unlike the northern, the southern affluents of the Ombilin do not follow longitudinal valleys hemmed in by the Barisan range and ranges of slate, limestone and sandstone. Here prevailing granite and diabase give rise to a complicated mountain system through which the rivers cleave their way in a curved and irregular course. South of the Middengebergte, however, the northern affluents of the Batang Hari, the Seliti, Gumanti, Si Potar, Mamun and Pangean, at least those in the west, again run in longitudinal valleys. These affluents and the Batang Hari itself (except the part at the mouth, Mamun-Simalidu) are navigable only by praus drawing not more than 12 in. (6) South Sumatra, so far as known, presents everywhere in its valleys the same character as that of the Batang Toru, Batang Gadis, Sumpur, &c. They also are closed in on the north and south by volcanoes which have here produced similar masses of tuff, with lakes and rivers of the same formation as in the north. Such are the valley of Korinchi, with the river of the same name, between the peak of Korinchi and Mt Raja; the valleys of Serampei and Sungei Tenang (as imperfectly known as that of the Korinchi), in which are to be sought the sources of the Tambesi and Asei, both affluents of the Jambi; the longitudinal valley of

Ketaun, in Lebong, flowing to the west coast, and of the upper Musi, flowing to the east coast; the valleys of Makakau and Selabung or the upper Komering, an affluent of the Musi, between Sebelat and Kaba. The Makakau and Selabung drain into Lake Ranau, which on the south side is dammed by the volcano Seminung. The southernmost longitudinal valley of Sumatra is that of the Semangka, which flows into the bay of the same name. Generally the lower valleys of the rivers lie at elevations of 600 to 1000 ft.; higher up they rise to 2500 or 3000 ft.; the mountain chains rise to 5500 ft.; the volcanoes tower up from 6500 to nearly 10,000 ft. (7) The section of south Sumatra between the eastern chain of old rocks and the east coast with its numerous river mouths is formed of the alluvium of sea and rivers. In the river-beds, however, and at some distance from the sea, older strata and eruptive rocks underlie the alluvium. The strata near the mountain chains and volcanoes consist of diluvial tuffs.

Geology.—The oldest rocks are gneiss, schist and quartzite, the schist often containing gold. They probably belong to several geological periods, but all were folded and denuded before the Carboniferous beds were deposited. They form the backbone of the island, and crop out on the surface at intervals along the mountain chain which runs parallel to the west coast. Here and there they are penetrated by granitic intrusions which are also Pre-Carboniferous. The next series of rocks consists of slates below and limestones above. It lies unconformably upon the older rocks; and the limestone contains *Fusulina*, *Phillipsia* and *Productus*, indicating that it belongs to the Upper Carboniferous. These beds are found only in northern Sumatra. They are accompanied by intrusions of diabase and gabbro, and they are sometimes folded, sometimes but little disturbed. No Permian beds are known, and for many years Mesozoic deposits were supposed to be entirely absent, but Triassic clays and sandstones with Daonella have been found in the upper part of the basin of the Kwalu (East Sumatra). They rest unconformably upon the Carboniferous beds, and have themselves been tilted to a steep angle. Cretaceous beds also have been recorded by Bücking. Tertiary deposits are very widely spread over the plains and low-lying country. They consist of breccias, conglomerates, sandstones, marls, and limestones, with seams of coal and lignite. The most valuable coal occurs in the Eocene beds. At the close of the Eocene period great eruptions of augite-andesite took place from two fissures which ran along the west coast. The Miocene consists chiefly of marls, with occasional beds of lignite and limestone. On the east coast it sometimes yields petroleum. The Pliocene occurs chiefly in the low-lying land and is generally covered by drift and alluvium. Sometimes it contains thick seams of lignite or brown coal.

The present volcanoes lie along a line (with offshoots) which runs parallel to the west coast, but some distance to the east of the fissures from which the early Tertiary lavas were poured. Lava streams are seldom emitted from these volcanoes, the material erupted consisting chiefly of ash and scoriae, which are spread over a very wide extent of country. Augite-andesite predominates, but basalt and rhyolite also occur.

Climate.—As throughout the whole of the Malayan Archipelago, so in Sumatra, which lies about equally balanced on both sides of the equator, the temperature stands at a high level subject to but slight variations. The monthly temperature mounts only from 77° F. in February to 80·6° in May, August and November. In the distribution of the rainfall, as dependent on the direction of the winds, the following parts of Sumatra must be distinguished: (1) south-east Sumatra, on which, as on Banka and Billiton, the heaviest rainfall occurs during the north-west monsoon, the annual volume of rainfall increasing from 98·4 in. in the east to 139 in. in the west. Of the 139 in. of yearly rainfall, 91·7 in. are brought by the north-west and 47·3 in. by the south-east monsoon. (2) The west coast. Here the rainfall for the year increases from the southern and northern extremities towards the middle. Benkulen, *e.g.* gets 126 in.; Singkel (2° 15′ N.), 172 in.; and Padang 184 in. in the year. Here, too, the prevailing rainfall is brought by the north-west monsoon, but in this belt its prevalence is not so pronounced, Padang getting 94 in. of rain during the north-west monsoon, against 90 in. during the south-east. The mountain chain immediately overhanging it, the high temperature of the sea washing it, the frequent thunderstorms to which it is subject, the moist atmosphere of its equatorial situation, and the shorter régime of the dry south-east wind are the principal causes of the heavier rainfall on the west coast. The higher stations of middle Sumatra, on the lee side of the western mountain chain, have a yearly rainfall of only 78·7 in. (3) The northern and north-eastern parts of Sumatra are swept by a variety of winds. The south-east wind, however, predominates. Blowing over land and in the direction of the longitudinal valleys, the south-east wind is comparatively dry, and thus favours the formation of steppes in the north such as the Toba plains. The north-east and south-west winds, on the other hand, being laden with the moisture of the sea, bring rain if they blow for any length of time.

Fauna.—Though Sumatra is separated from Java by so narrow a strait, both the zoologist and the botanist at once find that they have broken new ground on crossing to the northern island. The *Pachydermata* are strongly characteristic of the Sumatran fauna: not only are the rhinoceros (*Rh. sumatranus*), the *Sus vittatus*, and the tapir common, but the elephant, altogether absent from Java, is represented in Sumatra by a species considered by some to be peculiar. The Sumatran rhinoceros differs from the Javanese in having two horns, like the African variety. It is commonest in the marshy lowlands, but extends to some 6500 ft. above sea-level. The range of the elephant does not extend above 4900 ft. The wild *Bos sundaicus* does not appear to exist in the island. An antelope (*kambing-utan*) occurs in the loneliest parts of the uplands. The common Malay deer is widely distributed, *Cervus muntjac* less so. The orang-utang occurs, rarely, in the north-east. The siamang (*Siamanga syndactyla*) is a great ape peculiar to the island. The ungko (*Hylobates agilis*) is not so common. A fairly familiar form is the simpei (*Semnopithecus melalophus*). The chigah (*Cercocebus cynomolgus*) is the only ape found in central Sumatra in a tame state. The pigtail ape (*Macacus nemestrinus*)—as Raffles described it in his "Descriptive Catalogue of a Zoological Collection made in Sumatra," *Trans. Linn. Soc.* (1820), xiii. 243—is trained by the natives of Benkulen to ascend coco-nut trees to gather nuts. The *Galeopithecus volans* (*kubin*, flying cat or flying lemur) is fairly common. Bats of some twenty-five species have been registered; in central Sumatra they dwell in thousands in the limestone caves. The *Pteropus edulis* (*kalong*, flying fox) is to be met with almost everywhere, especially in the durian trees. The tiger frequently makes his presence felt, but is seldom seen; he prefers to prowl in what the Malays call tiger weather, that is, dark, starless, misty nights. The clouded tiger or *rimau bulu* (*Felis macroscelis*) is also known, as well as the Malay bear and wild dog. *Paradoxurus musanga* ("coffee-rat" of the Europeans) is only too abundant. The Sumatran hare (*Lepus netscheri*), discovered in 1880, adds a second species to the *Lepus nigricollis*, the only hare previously known in the Malay Archipelago. The *Manis javanicus* is the only representative of the Edentata. Some 350 species of birds are known, and the avifauna closely resembles that of the Malay Peninsula and Borneo, including few peculiar species.

Flora.—Rank grasses (*lalang*, *glaga*), which cover great areas in Java, have an even wider range in Sumatra, descending to within 700 or 800 ft. of sea-level; wherever a space in the forest is cleared these aggressive grasses begin to take possession of the soil, and if once they are fully rooted the woodland has great difficulty in re-establishing itself. Among the orders more strongly represented in Sumatra than in Java are the Dipterocarpaceae, Chrysobalanaceae, sclerocarp Myrtaceae, Melastomaceae, Begonias, Nepenthes, Oxalidaceae, Myristicaceae, Ternströmiaceae, Connaraceae, Amyridaceae, Cyrtandraceae, Epacridaceae and Eriocaulaceae. Many of the Sumatran forms which do not occur in Java are found in the Malay Peninsula. In the north the pine tree (*Pinus Merkusii*) has advanced almost to the equator, and in the south are a variety of species characteristic of the Australian region. The distribution of species does not depend on elevation to the same extent as in Java, where the horizontal zones are clearly marked; and there appears to be a tendency of all forms to grow at lower altitudes than in that island. A remarkable feature of the Sumatran flora is the great variety of trees that vie with each other in stature and beauty, and as a timber-producing country the island ranks high even among the richly wooded lands of the archipelago. Forest products—gums and resins of various sorts, such as gutta-percha—are valuable articles of export. The process of reckless deforestation is perceptible in certain districts, the natives often destroying a whole tree for a plank or rafter. The principal cultivated plants, apart from sugar-cane and coffee, are rice (in great variety of kinds), the coco-nut palm, the areng palm, the areca and the sago palms, maize, yams, and sweet potatoes; and among the fruit trees are the Indian tamarind, pomegranate, guava, papaw, orange and lemon. Even before the arrival of Europeans Sumatra was known for its pepper plantations; and these still form the most conspicuous feature of the south of the island. For the foreign market coffee is the most important of all the crops, the Padang districts being the chief seat of its cultivation. Benzoin was formerly obtained almost exclusively from Sumatra from the *Styrax benzoin*.

Population.—The following table gives the area and estimated population of the several political divisions of Sumatra and of the island as a whole (excluding the small part belonging to the Riouw-Lingga residency):—

Division.	Area in sq. m.	Population. 1900.
Sumatra, West Coast	31,649	1,527,297
Sumatra, East Coast	35,312	421,090
Benkulen	9,399	162,396
Lampong Districts	11,284	142,426
Palembang	53,497	804,299
Achin (Atjeh)	20,471	110,804
Total	161,612	3,168,312

Of the total population, about 5000 are Europeans, 93,000 Chinese, 2500 Arabs, 7000 foreigners of other nations, and the rest natives. In 1905 the total population was given as 4,029,505.

The natives of the mainland of Sumatra are all of Malay stock (those of the north being the most hybrid), but it is doubtful to what extent Malay has here absorbed pre-Malay blood. The different tribes vary in language, customs and civilization. No race of true Negrito type has been found. The Kubus (*q.v.*), a savage forest people of the highlands, were believed by some to be Negrito owing to the frizzled character of their hair, but it appears certain that they are Malayan. The north of Sumatra is occupied by the Achinese (see ACHIN). South of Achin and west of Lake Toba is the country of the Battas (*q.v.*) or Battaks. In the hill-country south of the lake are two forest tribes, Orang-ulu and Orang-lubu, pure savages of whom practically nothing is known, affiliated by most authorities to the Battas. The plains east of this territory are occupied by the Siaks, and farther south on the east coast are the Jambis, both Malays. Above Padang are the several tribes of the prosperous and comparatively civilized Menangkabos (*q.v.*). The Korinchis live among the mountains south of Padang, and farther south on the borders of Palembang and Benkulen are the Rejangers, a peculiar tribe who employ a distinctive written character which they cut with a kris on bamboo or lontar. The same character is employed by their immediate neighbours to the south, the Pasumas, who bear traces of Javanese influence. In the extreme south are the Lampong people, who claim descent from the Menangkabos, but have also an admixture of Javanese blood. The inhabitants of the islands west of Sumatra are of mixed origin. Simalu is peopled partly by Achinese and partly by Menangkabo settlers. They profess Mahommedanism but are practically savages. Nias (*q.v.*) has an interesting native population, apparently of pre-Malayan origin; and the Mentawi islands (*q.v.*) are inhabited by a race generally held to be a Polynesian settlement which has escaped fusion with Malayan stock. As regards education and the spread of Christianity among the natives, the west coast division is far in advance of the rest of the island. Here about 32,000 natives profess Christianity and there are about 300 schools; elsewhere schools are comparatively few and the adhesion to Christianity very slight.

Administrative Divisions and Towns.—In the west coast lands European influence, fertile soil, comparatively good roads, agriculture, timber, and coalfields have created populous settlements on the coast at Padang (the capital of the west coast, with 35,158 inhabitants in 1897, of whom 1640 were Europeans), Priaman, Natal, Ayer Bangis, Siboga, Singkel, and also on the plateaus at Fort de Kock, Payokombo, &c. In the east coast lands it is only at the mouths of rivers—Palembang at the mouth of the Musi, with 53,000 inhabitants, and Medan in Deli, the residence of the highest civil and military officials of the east coast, in which a fine government house has been erected—that considerable centres of population are to be found. Nine-tenths of the natives of Sumatra live by agriculture, the rest by cattle-rearing, fishing, navigation, and, last but not least, from the products of the forests; they are therefore little concentrated in towns.

The Dutch government of the west coast, extending along the shore of the Indian Ocean from 2° 53′ N. to 2° 25′ S., comprises the residencies of the Padang lowlands, Tapanuli and the Padang highlands. The governor has his residence at Padang, which is also the capital of the lowlands residency. Padang Sidempuan, the chief town of Tapanuli, lies inland, south of Mt Lubu Raja. The town of Siboga has considerable commercial importance, the bay on which it stands being one of the finest in all Sumatra. Bukit Tinggi, or, as it is commonly called, Fort de Kock, is the capital of the residency of the Padang highlands. To the government of the west Coast belong the following islands: Simalu; Banyak Islands, a small limestone group, well wooded and sparsely peopled; Nias; Batu Islands (Pulu Pini, Tana Masa, Tana Bala, &c.); Mentawi and Pegeh or Nassau Islands. The residency of Bankulen (*i.e. Bang Kulon*, " west coast ") lies along the west coast from the southern extremity of the west coast government to the south-western end of the island. The capital, Benkulen, is on the coast near Pulu Tiku, or Rat Island, in a low and swampy locality, and on an open roadstead. This was the chief establishment possessed by the British East India Company in Sumatra. Among other noteworthy places are Mokko-Mokko, with the old British fort Anna; Pasar Bintuhan, and Lais (Laye), the former seat of the British resident.

The residency of the Lampong districts is the southernmost in the island, being separated from Palembang by the Masuji River. It is partly mountainous, partly so flat as to be under water in the rainy season. The more important places are Telok Betong, chief town of the residency, Menggala (with a good trade), Gunung Sugi, Sukadana, Tanjong Karang, and Kota Agung.

The residency of Palembang consists of the former kingdom of this name and various districts more or less dependent on that monarchy. Between the mainland dependency of the Riouw-Lingga residency and the residency of Palembang lies Jambi, an extensive sultanate, of which a portion belongs to the residency of Palembang as a protectorate, the sultan having in his capital (also called Jambi) a Dutch " comptroller," who represents the resident of Palembang; another portion is claimed by a quasi-independent sultan who reigns in the interior. Of this interior very little was known until the scientific expedition despatched by the Dutch Royal Geographical Society towards the end of the 'seventies, but in 1901 an armed Dutch expedition, necessitated by frequent disturbances, penetrated right into the Jambi hinterland, the Gajo districts, where until then no European had ever trod. The town of Palembang is a large place on the river Musi, with 50,000 inhabitants (2500 Chinese), extensive barracks, hospitals, &c., a mosque (1740), considered the finest in the Dutch Indies, and a traditional tomb of Alexander the Great. The residency of Riouw, which embraces many hundreds of islands, great and small, also includes a portion of the Sumatra mainland, between the residencies of Palembang to the south and the east coast of Sumatra to the north. This is the old kingdom of Indragiri, and lies on either hand of the river of that name.

The residency of the east coast was formed in 1873 of the territory of Siak and its dependencies and the state of Kampar. In includes perhaps the richest and best-developed districts of northern Sumatra, namely, Deli (with an assistant-resident), Langkat, Serdang, &c.—districts little known in 1873, but by the beginning of the 20th century famous among the chief tobacco-producing countries in the world. Belawan is the harbour to Deli, but the capital is Medan, where the sultan and the Dutch resident reside. Belawan is connected with Medan by a railway, constructed before 1890 by a private company, almost entirely dependent for its earnings upon the numerous tobacco plantations, several of which belong to British corporations. The plantation labourers are almost entirely alien coolies, largely Chinese, and the Malays are comparatively few in number. The tobacco plantations of British North Borneo were nearly all started by planters from Deli.

The government of Achin (*q.v.*) occupies the northern part of the island. No little progress has been made by the Dutch even in this war-ridden territory. There is a railway in the lower valley of the Achin River, connecting the capital, Kotaraja, and neighbourhood with Olehleh, a good, free port, with an active trade, carried on by numerous steamers, both Dutch and foreign. Edi on the north-east coast, with another harbour, is capital of a sultanate which formerly owed allegiance to the sultan of Achin, but has formed a political division of the government of Achin since 1889, when an armed expedition restored order. Edi is a centre of the still extensive pepper trade, carried on mainly with the Chinese at Singapore and Penang, which island faces Edi.

Products and Industry.—Forests and natural vegetation cover a much larger part of Sumatra than of Java. Whereas in Java tall timber on the mountains keeps to altitudes of not less than 3000 ft., the tall timber on the mountains of Sumatra commonly descends below 1000 ft., and in many cases right down to the coast. In Sumatra, as in Java, the vegetation of the lowlands up to nearly 1000 ft. is distinct from the vegetation of the mountain slopes and plateaus from that elevation up to 4000 ft. and over. The principal exports from all the regencies alike are black and white pepper, bamboo (*rotan*), gums, caoutchouc, copra, nutmegs, mace and gambir. From the west coast and Palembang coffee is also exported, and from Deli, tobacco. The system of compulsory cultivation of coffee was abolished in Sumatra in 1908.

Sumatra possesses various kinds of mineral wealth. Gold occurs in the central region, where it is worked at a profit, and it has also been worked in the Menangkabo district and the interior of Padang. Tin is known, especially in Siak. Copper has been worked in the Padang highlands (most largely in the district of Lake Singkara) and at Muki in Achin. Iron is not infrequent. The most important mineral economically, however, is coal. Coal seams exist in the Malabuh valley (Achin), in the Sinamu valley, and on both sides of the Ombilin River; the Ombilin field was brought into especial notice by D. D. Veth of the 1877–79 expedition. The production of this field increased from 1730 tons in 1892 to 78,500 metric tons in 1899. The profit on the working, which is carried on by the state, is slight. Lignite of good quality is found in several localities. The production of petroleum began to be strongly developed towards the close of the 19th century; on the Lepan River in Langkat it mounted from 362,880 gallons in 1891 to 20,141,000 gallons in 1899. Muara Enim in Palembang also produces petroleum. Perlak, formerly a tributary state of Achin and now a political division of the Achin government, has become one of the chief centres of the petroleum industry. The crude oil is conveyed in pipes to Aru Bay, on the east coast, and refined in the island of Sembilan. Arsenic, saltpetre, alum, naphtha and sulphur may be collected in the volcanic districts. A systematic mineralogical survey has been undertaken in central Sumatra.

Roads and Railways.—In the west, with its long line of coast and numerous valleys, the transport of coffee has induced the construction of very good roads as far as the Lake of Toba, owing to the want of navigable rivers. There is a railway connecting not only the coalfields of the Ombilin valley with Padang, but also the Ombilin river and the Lake of Singkara with the most productive and densely populated plateaus and valleys, north and south of the line of the volcanoes Singalang, Merapi and Sago. A second railway in the district of Deli connects the inland plantations with the coast; and there is another, as already indicated, in the lower Achin valley. Good roads traverse the broad plains of Benkulen, Palembang and the Lampong districts.

History.—As far as is known, Sumatran civilization and culture are of Hindu origin; and it is not improbable that the island was the first of all the archipelago to receive the Indian immigrants who played so important a part in the history of the region. Certain inscriptions discovered in the Padang highlands seem to certify the existence in the 7th century of a powerful Hindu kingdom in Tanah Datar, not far from the site of the later capital of Menangkabo. In these inscriptions Sumatra is called the "first Java." The traces of Hindu influence still to be found in the island are extremely numerous, though far from being so important as those of Java. There are ruins of Hindu temples at Butar in Deli, near Pertibi, on the Panbi river at Jambi, in the interior of Palembang above Lahat, and in numerous other localities. One of the principal Hindu ruins is at Muara Takus on the Kampar river. The buildings (including a stupa 40 ft. high) may possibly date from the 11th century. At Pagar Rujung are several stones with inscriptions in Sanskrit and Menangkabo Malay. Sanskrit words occur in the various languages spoken in the island; and the *Ficus religiosa*, the sacred tree of the Hindu, is also the sacred tree of the Battas. At a later period the Hindu influence in Sumatra was strengthened by an influx of Hindus from Java, who settled in Palembang, Jambi and Indragiri, but their attachment to Sivaism prevented them from coalescing with their Buddhist brethren in the north. In the 13th century Mahommedanism began to make itself felt, and in course of time took a firm hold upon some of the most important states. In Menangkabo, for instance, the Arabic alphabet displaced the Kavi (ancient Javanese) character previously employed. Native chronicles derive the Menangkabo princes from Alexander the Great; and the Achinese dynasty boasts its origin from a missionary of Islam. The town of Samudera was at that period the seat of an important principality in the north of the island, whose current name is probably a corruption of this word. There is a village called Samudra near Pasei which possibly indicates the site.

Sumatra first became known to Europeans through the Portuguese, Diogo Lopes de Sequeira, in 1508. The Portuguese were the first to establish trading posts on the island, but at the end of the century they were driven out by the Dutch. At this time the most powerful native state in the island was Achin (*q.v.*). Elsewhere Dutch sovereignty was gradually extended—in 1664 over Indrapura; in 1666 over Padang, until by 1803 it was established over much of the southern part of the eastern lands, including Palembang. Meanwhile, in 1685 the British had acquired a footing in Benkulen, and between them and the Dutch there was always much jealousy and friction until in 1824 a treaty was made under which the British vacated Sumatra in favour of the Dutch, who reciprocated by giving up Malacca. In May 1825 Benkulen was taken over from the British. In the second half of the 19th century the Dutch found a succession of armed expeditions necessary to consolidate their power. Thus in 1851 a revolt was suppressed in Palembang, and an expedition was sent to the Lampong districts. In 1853 Raja Tiang Alam, ringleader of the revolt in Palembang, surrendeied. In 1858 an expedition was sent against Jambi; the sultan was dethroned and a treaty made with his successor. In 1860 Rejang was added to the Palembang residency. In 1863 there was an expedition against Nias, and in 1865 another against Asahan and Serdang (east coast). In 1873 war was declared against Achin. In 1876 there was an expedition against Kota Jutan (east coast) and the emancipation of slaves was carried out on the west coast. In 1878 Benkulen was made a residency, and the civil administration of Achin and dependencies was entrusted to a governor. From 1883 to 1894 the government, with the help of missionaries, extended its authority over the south-east and south-west of the island, and also over some of the lands to the east and north of Toba lake, including the districts of Toba, Silindong and Tanah Jawa, and in 1895 over the southern part of the peninsula of Samosir in Toba lake. Its jurisdiction was also extended over Tamiang, till then the northern frontier of the Dutch east coast of Sumatra. By military expeditions (1890–95) the Dutch influence on the Batang Hari, or Upper Jambi, was increased; as also in 1899 in the Lima Kotas[1] in central Sumatra, included within the territory of Siak. The war in Achin did not materially retard the development of Sumatra, and although the titular sultan of Achin continued a desultory guerrilla warfare against the Dutch in the mountainous woodlands of the interior, the almost inaccessible Pasei country, really active warfare has long ceased. All along the main coasts of the former sultanate of Achin military posts have been established and military roads constructed; even in Pedir, on the north coast, until 1899 the most actively turbulent centre of resistance of the sultan's party, and still later only pacified in parts, Dutch engineers were able to build a highway to connect the west with the east coast, and other works have been successfully carried out. Practically the whole of the island is now more or less explored and under control.

The literature dealing with Sumatra is very extensive. Of the older works the best known is W. Marsden, *History of Sumatra* (London, 1811). A full list of other older authorities will be found in P. J. Veth's *Aardrijkskundig Woordenboek van Nederl. Indië* (1869). Among later works one of great importance is *Midden-Sumatra; Reizen en Onderzoekingen der Sumatra Expeditie, 1877–1879* (Leiden, 1881, sqq.), edited by P. J. Veth. See also Brau de Saint-Pol Lias, *Île de Sumatra* (Paris, 1884); E. B. Kielstra, *Beschrijving van der Atjeh Oorlog* (1885–1886), and "Sumatras West-Kust van 1819–1825," in *Bijd. tot Land-, &c., Kunde* (1887); on the history of Palembang, west coast and the war in Achin, in *Indisch militair Tijdschrift* (1886–1889); *Tijdschr. bat. Gen.* (1887–1892). For topography and geology, see R. Fennema, "Topographische en geologische Beschrijving van het Noordelijk gedeelte . . . Westkust, &c.," *Jaarb. v. het Mijnwezen* (1887); R. D. M. Verbeek, *Topographische en geologische Beschrijving van een Deel van Sumatra's Westkust*, with atlas (Batavia, 1883); similar work dealing with south Sumatra, *Jaarb. v. het Mijnwezen* (1881), and *Supplement* (1887). SUMBA (TJENDANA, or SANDALWOOD), one of the Lesser Sunda Islands in the Dutch East Indies, lying south of Flores, from which it is separated by Sumba strait, about 10° S., 120° E. It has an area of about 4600 sq. m., consists of a plateau with an extreme elevation of about 3300 ft., and appears to be composed mainly of sedimentary rocks. It has a large Malay population (estimated at 200,000). Some trade is carried on in cotton, ponies, edible birds' nests, tortoiseshell, &c., mainly by Bugis and Arabs, the chief centre for which is Waingapu or Nangamessi on the north-east coast. Sumba is included in the Dutch residency of Timor, together with the lesser island of Savu, to the east. From this last island the sea is enclosed by Timor, Sumba and the islands between them, and Flores and the chain of islands east of it is called the Savu Sea.

[1] "Kota" means settlement or township, and a great many districts have been named from the number of kotas they contain; *e.g.* the VII. Kotas, the VIII. Kotas, &c.

SUMBAWA (Dutch *Soembawa*), one of the Little Sunda islands in the Dutch East Indies, east of Lombok, from which it is separated by the narrow Alas Strait. It has an area of 4300 sq. m., or, including the neighbouring islands, 5240 sq. m. The deep bay of Salé or Sumbawa on the north divides the island into two peninsulas, and the isthmus is further reduced by the narrower Bay of Chempi on the south. The eastern peninsula is deeply indented on the north by the Bay of Bima. Four mountain chains cross the island in a west to east direction. The northern, as in Bali and Lombok, is of volcanic origin. Tambora, forming a minor peninsula east of Sumbawa Bay, is said to have lost a third of its elevation in the eruption of 1815, but is still 9055 ft. high. In the southern chain is found a limestone formation analogous to that in Bali, Lombok and Java. Between these two chains are round hills consisting of lavas or sometimes of volcanic tuffs, covered with the long silvery grass which also clothes vast prairies in Java and Sumatra. There are no navigable streams. The climate and productions are not unlike those of Java, though the rains are heavier, the drought more severe, and the fertility less. Sulphur, arsenic, asphalt and petroleum exist. The natives live solely by agriculture. But out of a total population of about 75,000 there are 11,000 foreigners, living mostly by trade and navigation. The natives consist of Sumbawans proper, a people of Malayan stock; of Buginese and Macassar immigrants, and of wild tribes of the mountains of whom nothing is known. Mahommedanism prevails throughout the island, except among the mountain tribes.

Politically Sumbawa, with its four independent states, belongs to the confederated states of the government of Celebes and its dependencies, a situation to be explained by the fact of the old supremacy of the Macassaresi over Sumbawa, Flores and Sumba. The independent states are Sumbawa proper, Dompo, Sangar and Bima. Two other states on the northern extremity of the island were so far devastated by the Tambora eruption of 1815 that their territory, after lying for long uninhabited, was in 1866 divided between Dompo and Sangar. Sumbawa proper occupies the western peninsula. The residence of the sultan is Sumbawa on the north coast. It is surrounded with a palisade and ditches. The inhabitants of this state employ sometimes the Malay and sometimes the Macassar character in writing. A considerable trade is carried on in the export of horses, buffaloes, goats, dinding (dried flesh), skins, birds' nests, wax, rice, katyang, sappanwood, &c. Sumbawa entered into treaty relations with the Dutch East India Company in 1674. Dompo is the western half of the eastern peninsula. The capital of the state, Dompo, lies in the heart of the country, on a stream that falls into Chempi Bay. Bada, the sultan's residence, is farther west. Sangar occupies the north-western promontory of the island, and Bima the extreme east. Bima or Bodjo, the chief town of the latter state, lies on the east side of the Bay of Bima; it has a stone-walled palace and a mosque, as well as a Dutch fort.

See Zollinger, "Soembawa," in *Verhandelingen van het Batav. Genootschap*, xxiii.; Ligtvoet, "Anteekeningen betreffende den economischen Toestand en de Ethnographie van Soembawa," in *Tijdschr. Bat. Gen.* xxiii.

SUMBUL, or SUMBAL, also called Musk Root, a drug occasionally employed in European medical practice. It consists of the root of *Ferula sumbul*, Hook., a tall Umbelliferous plant found in the north of Bokhara, its range apparently extending beyond the Amur. It was first brought to Russia in 1835 as a substitute for musk; and in 1867 was introduced into the British pharmacopoeia. The root as found in commerce consists of transverse sections an inch or more in thickness and from 1 to 3 or more inches in diameter. It has a dark thin papery bark, a spongy texture, and the cut surface is marbled with white and blackish or pale brown; it has a musky odour and a bitter aromatic taste. The action and uses of the drug are the same as those of asafetida (*q.v.*) It owes its medicinal properties to a resin and an essential oil. Of the former it contains about 9% and of the latter ⅓ %. The resin is soluble in ether and has a musky smell, which is not fully developed until after contact with water.

Under the name of East Indian sumbul, the root of *Dorema ammoniacum*, Don., has occasionally been offered in English commerce. It is of a browner hue, has the taste of ammoniacum, and gives a much darker tincture than the genuine drug; it is thus easily detected. The name "sumbal" (a word of Arabic origin, signifying a spike or ear) is applied to several fragrant roots in the East, the principal being *Nardostachys jatamansi*, D.C. (see SPIKENARD). West African sumbul is the root of a species of *Cyperus*.

SUMER and **SUMERIAN.** The Babylonian name Shumer was used in the cuneiform inscriptions together with Akkad, viz. *mat Shumeri u Akkadi*, "land of S. and A.," to denote Babylonia in general (see AKKAD). In the non-Semitic ideographic documents the equivalent for Shumer is *Kĕngi*, which seems to be a combination of *kĕn*, "land" + *gi*, "reed," *i.e.* "land of reeds," and appropriate designation for Babylonia, which is essentially a district of reedy marshes formed by the Tigris and Euphrates. It was formerly thought that Shumer was employed especially to denote the south of Babylonia, while Akkad was used only of the north, but this view is no longer regarded as tenable. It is more probable that the expression Shumer designated the whole of Babylonia in much the same manner as did Akkad, and that the two words "Shumer and Akkad" were used together as a comprehensive term. That Shumer actually did mean all Babylonia appears evident from the biblical use of Shinar = Shumer to describe the district which contained the four chief Babylonian cities, viz. Babel, Erech, Accad and Calneh (Gen. x. 10), which, according to the Old Testament account, constituted the beginnings of Nimrod's kingdom. The identity of Shinar and Shumer is also demonstrated by the Septuagint rendering of Shinar in Isaiah xi. 11 by "Babylonia." In short, there can be no doubt that the biblical name Shinar was practically equivalent to the *mat Shumeri u Akkadi* = non-Semitic *Kêngi-Uri* of the Babylonian inscriptions. Furthermore, the fact that the Syriac *Sen'ar* = Shinar was later used to denote the region about Bagdad (northern Babylonia) does not necessarily prove that Shinar-Shumer meant only northern Babylonia, because, when the term *Sen'ar* was applied to the Bagdad district the great southern Babylonian civilization had long been forgotten and "Babylonia" really meant only what we now know as northern Babylonia.

The actual meaning of the word Shumer is uncertain. Dr T. G. Pinches has pointed out[1] that Shumer may be a dialectic form of an as yet unestablished non-Semitic form, Shenger, just as the non-Semitic word *dimmer*, "god," is equivalent to another form, *dingir*. Others have seen in the ancient Babylonian place-name *Gir-su* an inversion of *Su-gir* = *Su-n̂gir*, which has also been identified with Shumer. In this connexion Hommel's theory[2] should be mentioned, that the word Shumer was a later palatalization of *Ki-imgir*, "land of Imgir" = *Shi-imgir*, subsequently *Shingi* with palatalized *k* = *sh* and elision of the final *r*. The form *imgir* (*imgur*), however, as a place-name for Babylonia is uncertain. All that can be said at present about this difficult etymology is that in the non-Semitic Babylonian the medial *m* represented quite evidently an indeterminate nasal which could also be indicated by the combination *n̂g*. Hence we find Shumer, probably pronounced *Shuwer*, with a sound similar to that heard to-day in the Scottish Gaelic word *lamh*, "hand"; viz. a sort of nasalized *w*. This gave rise to the later inaccurate forms: Greek, *Senaar*; Syriac, *Sen'ar*; and biblical Hebrew, Shinar = *Shin̂gar*.

The so-called "Sumerian problem," which has perplexed Assyriologists for many years, may be briefly stated as follows. In a great number of Babylonian inscriptions an idiom has long been recognized which is clearly not ordinary Semitic in character. This non-Semitic system, which is found, in many instances, on alternate lines with a regular Semitic translation, in other cases in opposite columns to a Semitic rendering, and again without any Semitic equivalent at all, has been held by one school, founded and still vigorously defended by the distinguished French Assyriologist, Joseph Halévy, to be nothing more than a priestly system of cryptography based, of course, on the then current Semitic speech. This cryptography, according to some of the Halévyans, was read aloud in Semitic, but, according to other expositors, the system was read as an "ideophonic," secret, and purely artificial language.

The opposing school (the Sumerists) insists that these

[1] Hastings's *Dict. Bible*, iv. 503. [2] Ibid. i. 224b.

non-Semitic documents were evidently in an agglutinative language, naturally not uninfluenced by Semitic elements, but none the less essentially non-Semitic in origin and fundamental character. Scholars of this opinion believe that this language, which has been arbitrarily called "Akkadian" in England and "Sumerian" on the European continent and in America, was primitively the speech of the pre-Semitic inhabitants of the Euphratean region who were conquered by the invading Semites. These invaders, according to this latter view, adopted the religion and culture of the conquered Sumerians; and, consequently, the Sumerian idiom at a comparatively early date began to be used exclusively in the Semitic temples as the written vehicles of religious thought in much the same way as was the medieval Latin of the Roman Church. The solution of this problem is of vital importance in connexion with the early history of man's development in the Babylonian region.

The study of the Sumerian vocabulary falls logically into three divisions. These are (1) the origin of the cuneiform signs, (2) the etymology of the phonetic values, and (3) the elucidation of the many and varied primitive sign-meanings.

Previous to Professor Friedrich Delitzsch's masterly work on the origin of the most ancient Babylonian system of writing,[1] no one had correctly understood the facts regarding the beginnings of the cuneiform system, which is now generally recognized as having been originally a pure picture writing which later developed into a conventionalized ideographic and syllabic sign-list. In order to comprehend the mysteries of the Sumerian problem a thorough examination of the beginning of every one of these signs is, of course, imperative, but it is equally necessary that every phonetic Sumerian value and word-combination be also studied, both in connexion with the equivalent signs and with other allied phonetic values. This etymological study of Sumerian is attended with incalculable difficulties, because nearly all the Sumerian texts which we possess are written in an idiom which is quite evidently under the influence of Semitic. With the exception of some very ancient texts, the Sumerian literature, consisting largely of religious material such as hymns and incantations, shows a number of Semitic loanwords and grammatical Semitisms, and in many cases, although not always, is quite patently a translation of Semitic ideas by Semitic priests into the formal religious Sumerian language. Professor Paul Haupt may be termed the father of Sumerian etymology, as he was really the first to place this study on a scientific basis in his *Sumerian Family Laws* and *Akkadian and Sumerian Cuneiform Texts*.[2] It is significant that all phonetic and grammatical work in Sumerian tends to confirm nearly every one of Haupt's views. Professors Peter Jensen and Zimmern have also done excellent work in the same field and, together with Haupt, have established the correct method of investigating the Sumerian vocables, which should be studied only in relation to the Sumerian literature. Sumerian words should by no means be compared with words in the idioms of more recent peoples, such as Turkish, in spite of many tempting resemblances.[3] Until further light has been thrown on the nature of Sumerian, this language should be regarded as standing quite alone, a prehistoric philological remnant, and its etymology should be studied only with reference to the Sumerian inscriptions themselves. On the other hand, grammatical and constructional examples may be cited from other more modern agglutinative idioms, in order to establish the truly linguistic character of the Sumerian peculiarities and to disprove the Halévyan contentions that Sumerian is really not a language at all.[4]

It is not surprising that Halévy's view as to the cryptographic nature of Sumerian should have arisen. In fact, the first impression given by the bewildering labyrinth of the Sumerian word-list is the conclusion that such a vocabulary could never have arisen in a regularly developed language. For example, anyone studying Brünnow's *List*[5] will find the same sign denoting pages of meanings, many of which have apparently no connexion with any other meaning belonging to the sign in question. A great multiplicity of meanings is also attributed, apparently quite arbitrarily, to the same sign, sound-value or word. In these instances, however, we can explain the difficulty away by applying that great fundamental principle followed by the Semitic priests and scribes who played with and on the Sumerian idiom, and in the course of many centuries turned what was originally an agglutinative language into what has almost justified Halévy and his followers in calling Sumerian a cryptography. This principle is that of popular etymology, *i.e.* of sound-association and idea-association which has brought together in the word-lists many apparently quite distinct meanings, probably primarily for purposes of mnemonic aid. The present writer in his *Materials for a Sumerian Lexicon* has mentioned this ruling phenomenon again and again. A very few examples, however, will suffice here. Thus the word *ag*=the sign RAM=*râmu*, "love" (proper meaning) is associated with *ramâmu*, "to roar," for phonetic reasons only. The word *a*= the sign A= "water" (original meaning) can indicate anything whatever connected with the idea moisture. Thus, *a*="water, moisture, weep, tears, inundate, irrigate," &c. The word *a* can also mean "shining, glistening," an idea evidently developed from the shining rippling of water. Note that in Turkish *su* means both "water" and "the lustre of a jewel," while in English we speak of "gems of the first water." The combination *a-má-tu*, literally "water enter ship," means *abûbu*, "deluge," ordinarily, but in one passage *a-má-tu* is made the equivalent of *shabûbu*, "flame," a pure pun on *abûbu*, "deluge." Examples of this, the leading principle which was followed by the framers of the Sumerian system, might be cited almost *ad infinitum*.

Facts of this character taken by themselves would perhaps be sufficient to convince most philologists that in Sumerian we have an arbitrarily compounded cryptography just as Halévy believes, but these facts cannot be taken by themselves, as the evidences of the purely linguistic basis of Sumerian are stronger than these apparent proofs of its artificial character.

Briefly considered there are six most striking proofs that the Sumerian was based on a primitive agglutinative language. These may be tabulated concisely as follows:—

1. Sumerian presents a significant list of internal phonetic variations which would not have been possible in an arbitrarily invented language. Thus, taking the vowels alone; *e*=*a* by the principle of *umlaut*. Hence, we find the words *ga* and *ge*, *a* and *e* for the same idea respectively. The vowel *i* could become *e* as *de*=*di*, &c. Consonantal variation is most common. Thus, *b*=*m*, as *barun*=*marun*. Compare the modern Arabic pronunciation *Maalbek* for *Baalbek*. Perhaps the most interesting of these consonantal interchanges is that occurring between *n* and the sibilants *sh* and *z*; *ner*=*sher*; *na*=*za*, which by some scholars has been declared to be phonetically impossible, but its existence is well established between the modern Chinese colloquial idioms. For example, Pekingese *zhen*, Hakka *nyin*, Fuchow *nöng*, Ningpo *zhing* and *nying*, Wönchow *zang* and *nang* all ="man." This demonstrates beyond a doubt the possibility of a strongly palatalized *n* becoming a palatal sibilant or vice versa, between which utterances there is but a very slight tongue movement.

The discussion of these phenomena brings us to another point which precludes the possibility of Sumerian having been merely an artificial system, and that is the undoubted existence in this language of at least two dialects, which have been named, following the inscriptions, the *Eme-ku*, "the noble or male speech," and the *Eme-sal*, "the woman's language." The existence and general phonetic character of the "woman's language" were first pointed out by Professor Paul Haupt,

[2] *Die sumerischen Familiengesetze* (1879). *Die akkadische Sprache* (Berlin, 1883). *Akkadische und sumerische Keilschrifttexte* (Leipzig, 1881). See especially his Sumerian grammar in this latter work, pp. 133–147.

[3] Cf. A. H. Sayce's interesting article in Philological Society (1877–1878), pp. 1–20.

[4] Prince, *Materials for a Sumerian Lexicon*, pp. 18, 21.

[5] R. E. Brünnow, *A Classified List of all Simple and Compound Ideographs* (1889).

who cited, for example, the following very common interdialectic variations: Eme-ku *gir* = Eme-sal *meri*, "foot"; Eme-ku *ner* = Eme-sal *sher*, "ruler"; Eme-ku *duga* = Eme-sal *zeba*, "knee," &c. Such phonetic and dialectic changes, so different from any of the Semitic linguistic phenomena, are all the more valuable because they are set before us only by means of Semitic equivalents. Certainly no cryptography based exclusively on Semitic could exhibit this sort of interchange.

It should be added here in passing that the geographical or tribal significance of these two Sumerian dialects has never been established. There can be no doubt that Eme-sal means "woman's language," and it was perhaps thus designated because it was a softer idiom phonetically than the other dialect. In it were written most of the penitential hymns, which were possibly thought to require a more euphonious idiom than, for example, hymns of praise. It is doubtful whether the Eme-sal was ever really a woman's language similar in character to that of the Carib women of the Antilles, or that of the Eskimo women of Greenland. It is much more likely that the two dialects were thus designated because of their respectively harsh and soft phonetics.[1]

2. Sumerian has a system of vowel harmony strikingly like that seen in all modern agglutinative languages, and it has also vocalic dissimilation similar to that found in modern Finnish and Esthonian. Vocalic harmony is the internal bringing together of vowels of the same class for the sake of greater euphony, while vocalic dissimilation is the deliberate insertion of another class of vowels, in order to prevent the disagreeable monotony arising from too prolonged a vowel harmony. Thus, in Sumerian we find such forms as *numunnib-bi*, "he speaks not to him," where the negative prefix *nu* and the verbal prefix *mun* are in harmony, but in dissimilation to the infix *nib*, "to him," and to the root *bi*, "speak," which are also in harmony. Compare also *an-sud-dam*, "like the heavens," where the ending *dam* stands for a usual *dim*, being changed to a hard *dam* under the influence of the hard vowels in *an-sud*.

3. Sumerian has only postpositions instead of prepositions, which occur exclusively in Semitic. In this point also Sumerian is in accord with all other agglutinative idioms. Note Sumerian *e-da*, "in the house" (*e*, "house," +*da*, "in," by dissimilation), and compare Turkish *ev*, "house," *de*, "in," and *evde*, "in the house."

4. The method of word formation in Sumerian is entirely non-Semitic in character. For example, an indeterminative vowel, *a*, *e*, *i* or *u*, may be prefixed to any root to form an abstract; thus, from *me*, "speak," we get *e-me*, "speech"; from *ra*, "to go," we get *a-ra*, "the act of going," &c. In connexion with the very complicated Sumerian verbal system[2] it will be sufficient to note here the practice of infixing the verbal object which is, of course, absolutely alien to Semitic. This phenomenon appears also in Basque and in many North American languages.

5. Sumerian is quite devoid of grammatical gender. Semitic, on the other hand, has grammatical gender as one of its basic principles.

6. Furthermore, in a real cryptography or secret language, of which English has several, we find only phenomena based on the language from which the artificial idiom is derived. Thus, in the English "Backslang," which is nothing more than ordinary English deliberately inverted, in the similar Arabic jargon used among school children in Syria and in the Spanish thieves' dialect, the principles of inversion and substitution play the chief part. Also in the curious tinker's "Thary" spoken still on the English roads and lanes, we find merely an often inaccurately inverted Irish Gaelic. But in none of these nor in any other artificial jargons can any grammatical development be found other than that of the language on which they are based.

7. All this is to the point with regard to Sumerian, because these very principles of inversion and substitution have been cited as being the basis of many of the Sumerian combinations. Deliberate inversion certainly occurs in the Sumerian documents, and it is highly probable that this was a priestly mode of writing, but never of speaking; at any rate, not when the language was in common use. It is not necessary to imagine, however, that these devices originated with the Semitic priesthood. It is quite conceivable that the still earlier Sumerian priesthood invented the method of orthographic inversion, which after all is the very first device which suggests itself to the primitive mind when endeavouring to express itself in a manner out of the ordinary. For example, evident Sumerian inversions are *Gibil*, "the fire god," for *Bil-gi*; *ushar* for Sem. *sharru*, "king," &c.

It is, moreover, highly probable that Sumerian had primitively a system of voice-tones similar to that now extant in Chinese. Thus, we find Sumerian *ab*, "dwelling," "sea"; *ab*, "road," and *-ab*, a grammatical suffix, which words, with many others of a similar character, were perhaps originally uttered with different voice-tones. In Sumerian, the number of conjectural voice-tones never exceeds the possible number eight.

It is also clear that Sumerian was actually read aloud, probably as a ritual language, until a very late period, because we have a number of pure Sumerian words reproduced in Greek transliteration; for example, *Delephat* = *Dilbat*, "the Venus-star"; *Illinos* = the god *Illil* = Bêl; *aidô* = *itu*, "month," &c.

In view of the many evidences of the linguistic character of Sumerian as opposed to the one fact that the language had engrafted upon it a great number of evident Semitisms, the opinion of the present writer is that the Sumerian, as we have it, is fundamentally an agglutinative, almost polysynthetic, language, upon which a more or less deliberately constructed *pot-pourri* of Semitic inventions was superimposed in the course of many centuries of accretion under Semitic influences. This view stands as a connecting link between the extreme idea of the Halévyan school and the extreme idea of the opposing Sumerist school.

SUMMANUS, according to some, an old Sabine or Etruscan deity; the name, however, is Latin, formed by assimilation from *sub-mānus* (cf. *mane*, *Matuta*), signifying the god of the time "before the morning." His sphere of influence was the nocturnal heavens, thunderstorms at night being attributed to him, those by day to Jupiter. Summanus had a temple at Rome near the Circus Maximus, dedicated at the time of the invasion of Italy by Pyrrhus, king of Epirus (278), when a terracotta image of the god (or of Jupiter himself) on the pediment of the Capitoline temple was struck by lightning and hurled into the river Tiber. Here sacrifice was offered every year to Summanus on the 20th of June, together with cakes called *summanalia* baked in the form of a wheel, supposed to be symbolical of the car of the god of the thunderbolt. In Plautus (*Bacchides* iv. 8, 54) Summanus and the verb *summanare* are used for the god of thieves and the act of stealing, with obvious reference to Summanus as a god of night, a time favourable to thieves and their business. The later explanation that Summanus is a contraction from Summus Manium (the greatest of the Manes), and that he is to be identified with Dis Pater, is now generally rejected.

SUMMARY JURISDICTION. In the widest sense this phrase in English law includes the power asserted by courts of record to deal *brevi manu* with contempts of court without the intervention of a jury. Probably the power was originally exercisable only when the fact was notorious, *i.e.* done in presence of the court. But it has long been exercised as to extra curial contempts (see CONTEMPT OF COURT). The term is also applied to the special powers given by statute or rules to the High Court of Justice and to county courts for dealing with certain classes of causes or matters by methods more simple and expeditious than the ordinary procedure of an action (see SUMMONS). But the phrase in modern times is applied almost exclusively to certain forms of jurisdiction exercised by justices of the peace out of general or quarter sessions, and without the assistance of a jury.

Ever since the creation of the office of *justice of the peace* (*q.v.*) the tendency of English legislation has been to enable them to deal with minor offences without a jury. Legislation was necessary because, as Blackstone says, except in the case of contempts the common law is a stranger to trial without a jury, and because even when an offence is created by statute the procedure for trying must be by indictment and trial before a jury, unless by the statute creating the offence or some other statute another mode of trial is provided. In one remarkable instance power is given by an act of 1725 (12 Geo. I. c. 29, s. 4) to judges of the superior courts summarily to sentence to transportation (penal servitude) a solicitor practising after conviction of barratry, forgery or perjury (Stephen, *Dig. Crim. Law*, 6th ed., 113). In other words all the summary jurisdiction of justices of the peace is the creation of statute. The history of the gradual development of the summary jurisdiction of justices of the peace is stated in Stephen's *Hist. Crim. Law*, vol. i. ch. 4. The result of legislation is that summary jurisdiction has been conferred by statutes and by-laws as to innumerable petty offences of a criminal or quasi-criminal character (most of which in French law would be described as *contraventions*), ranging through every letter of the alphabet. The most important perhaps are those under the Army, Game, Highway, Licensing, Merchant Shipping, Post Office, Public Health, Revenue and Vagrancy Acts.

A court of summary jurisdiction is defined in the Interpretation Act 1889 as "any justice or justices of the peace or other magistrate, by whatever name called, to whom jurisdiction is given by, or who is authorized to act under, the Summary Jurisdiction Acts, whether in England, Wales or Ireland, and whether acting under the Summary Jurisdiction Acts or any of them or any other act or by virtue of his commission or under the common law" (52 & 53 Vict. c. 63, s. 13 [11]). This definition does not apply to justices of the peace sitting to hold a preliminary inquiry as to indictable offences, or in the discharge of their quasi-administrative functions as licensing authority. The expression "Summary Jurisdiction Acts" means as to England and Wales the Summary Jurisdiction Acts of 1848 (11 & 12 Vict. c. 42) and 1879 (42 & 43 Vict. c. 49) and any act amending these acts or either of them. These acts define the procedure to be followed by justices in those cases in which they are empowered *by statute* to hear and determine civil or criminal cases without the intervention of a jury or the forms of an action or indictment at law or a suit in equity. Besides these two acts the procedure as to the exercise of summary jurisdiction is also regulated by acts of 1857 (20 & 21 Vict. c. 1, c. 43), 1884 (47 & 48 Vict. c. 43) and 1899 (62 & 63 Vict. c. 22), and by the Summary Jurisdiction Process Act 1881 (44 & 45 Vict. c. 24).

The act of 1848 repealed and consolidated the provisions of a large number of earlier acts. The act of 1857 provided a mode of appeal to the High Court by case stated as to questions of law raised in summary proceedings. The act of 1879 amended the procedure in many details with the view of uniformity, and enlarged the powers of justices to deal summarily with certain classes of offences ordinarily punishable on indictment. The act gives power to make rules regulating details of procedure. The rules now in force were made in 1886, but have since been amended in certain details. The act of 1884 swept away special forms of procedure contained in a large number of statutes, and substituted the procedure of the Summary Jurisdiction Acts. The act of 1899 added the obtaining of property by false pretences to the list of indictable offences which could *sub modo* be summarily dealt with. The statutes above mentioned form a kind of code as to procedure and to some extent also as to jurisdiction.

As already stated, to enable a justice to deal summarily with an offence, whether created by statute or by-law, some statutory authority must be shown. A very large number of petty offences (contraventions) have been created (*e.g.* poaching, minor forms of theft, malicious damage and assault), and are annually being created (1) by legislation, or (2) by the by-laws of corporations made under statutory authority, or (3) by departments of state acting under such authority. The two latter classes differ from the first in the necessity of proving by evidence the existence of the by-law or statutory rule, and if need be that it is *intra vires.*

In the case of offences which are primarily made punishable only on summary conviction, the accused, if the maximum punishment is imprisonment for over three months, can elect to be tried by a jury (act of 1879, s. 17).

In the case of offences which are primarily punishable only on indictment, power to convict summarily is given in the following cases:—

1. All indictable offences (except homicide) committed by children over seven and under twelve, if the court thinks it expedient and the parent or guardian does not object (1879, s. 10).

2. All indictable offences (except homicide) committed by young persons of twelve and under sixteen, if the young person consents after being told of his right to be tried by a jury (1879, s. 11; 1899, s. 2).

3. The indictable offences specified in sched. 1, col. 2 of the act of 1879 and in the act of 1899, if committed by adults, if they consent to summary trial after being told of their right to be tried by a jury (1879, s. 12).

4. The indictable offences specified in sched. 1, col. 1 of the act of 1879 and the act of 1899, if committed by an adult who pleads guilty after due caution that if he does so he will be summarily convicted (1879, s. 13).

Adults cannot be summarily dealt with under 3 or 4 if the offence is punishable by law with penal servitude owing to previous conviction *or indictment* of the accused (1879, s. 14).

It will be observed that as to all the indictable offences falling under heads 1 to 4, the summary jurisdiction depends on the consent of the accused or a person having authority over him after receiving due information as to the right to go to a jury, and that the punishments on summary conviction in such cases are not those which could be imposed after conviction or indictment, but are limited as follows:—

Case 1. Imprisonment for not more than one month or fine not exceeding 40s. and (or) whipping of male children (not more than six strokes with a birch); sending to an industrial school or reformatory.

Case 2. Imprisonment with or without hard labour for not more than three months or fine not exceeding £10 and (or) whipping of males (not more than twelve strokes with a birch); sending to an industrial school or reformatory.

Case 3. Imprisonment for not more than three months with or without hard labour or fine not exceeding £20.

Case 4. Imprisonment with or without hard labour for not over six months.

These limitations of punishment have had a potent effect in inducing culprits to avoid the greater risks involved in a jury trial.

Where the offence is indictable the accused is brought before the justices either on arrest without warrant or on warrant or summons under the Indictable Offences Act 1848, and the summary jurisdiction procedure does not apply till the necessary option has been taken.

Where the offence is indictable only at the election of the accused the summary jurisdiction procedure applies until on being informed of his option the accused elects for jury trial (act of 1879, s. 17).

In the case of an offence punishable on summary conviction the procedure is ordinarily as follows:—

Information, usually oral, is laid before one or more justices of the peace alleging the commission of the offence. An information must not state more than a single offence, but great latitude is given as to amending at the hearing any defects in the mode of stating an offence. Upon receipt of the information the justice may issue his summons for the attendance of the accused at a time and place named to answer the charge. It is usual to summon to a petty sessional court (*i.e.* two justices or a stipendiary magistrate, or, in the city of London, an alderman). The summons is usually served by a constable. If the accused does not attend in obedience to the summons, after proof of service the court may either issue a warrant for his arrest or may deal with the charge in his absence.

Occasionally a warrant is issued in place of a summons in the first instance, in which case the information must be laid in writing and be verified by oath. The proceedings must be begun, *i.e.* by laying the information, not later than six months after the commission of the offence, unless by some particular statute another period is named or unless the offence is what is called a continuing offence.

In a certain number of summary cases the accused is arrested under statutory authority without application to a justice, *e.g.* in the case of rogues and vagabonds and certain classes of offences committed in the street in view of a constable or by night. Whether the accused is brought before the court on arrest with or without warrant or attends in obedience to summons, the procedure at the hearing is the same. The hearing is ordinarily before a petty sessional court, *i.e.* before two or more justices sitting at their regular place of meeting or some place temporarily appointed as the substitute for the regular court-house, or before a stipendiary magistrate, or in the city of London an alderman, sitting at a place where he may by law do alone what in other places may be done by two justices (1879, s. 20; 1889, s. 13). A single justice sitting alone in the ordinary court-house or two or more justices sitting together at an occasional court-house have certain jurisdiction to hear and determine the case, but cannot order a fine of more than 20s. or imprisonment for more than fourteen days (1879, s. 20 [7]). The hearing must be in open court, and parties may appear by counsel or solicitor. If both parties appear, the justices must hear and determine the case. If the defendant does not appear, the court may hear and determine in his absence, or may issue a warrant and adjourn the hearing until his apprehension. Where the defendant is represented by solicitor or counsel but is not himself present it is usual, except in serious cases, to proceed in his absence. If the defendant is present the substance of the information is stated to him and he is asked whether he is guilty or not guilty. If he pleads guilty the court may proceed to conviction. If he does not the court hears the case, and witnesses for the prosecution and defence are examined and cross-examined. If the complainant does not appear, the justices may dismiss the complaint or adjourn the hearing.

If necessary rebutting evidence may be called. The prosecutor is not allowed to reply in the case of the defendant. On the completion of the evidence the court proceeds to convict or acquit. Where the case is proved but is trifling the court may, without proceeding to conviction, make an order dismissing the information subject to payment of damages for injury or compensation for loss up to £10 or any higher limit fixed by statute as to the offence, and costs, or discharging the accused conditionally on his giving security for good behaviour and on paying damages and costs (1907, c. 17, s. 1). To this order probationary conditions may be attached (s. 2). Subject to this provision the punishment which may be enforced depends as a general rule on the statute or by-law defining the offence, and consists in imprisonment and (or) fine, except in cases where a minimum fine is stipulated for by a treaty, &c., with a foreign state, *e.g.* in sea fishery conventions. The court may mitigate the fine in the case of a first offence, even in a revenue case, or may reduce the period of imprisonment and impose it without hard labour, or substitute a fine not exceeding £25 for imprisonment. A scale is prescribed for imprisonment on failure to pay money, fines, or costs, adjudged to be paid on a conviction, or in default of a sufficient distress to satisfy the sum adjudged (1879, s. 5). Instead of sending the defendant to prison for not paying fine and costs the court may direct its levy by distress warrant, or may accept payment by instalments. In the case of distress the wearing apparel and bedding of the defendant and his family, and to the value of £5 the tools and implements of his trade, may not be taken (act of 1879, s. 21). If the defendant after going to prison can pay part of the money his imprisonment is reduced proportionally (Prison Act 1898, s. 9). The imprisonment is without hard labour unless hard labour is specially authorized by the act on which the conviction is founded. The maximum term of imprisonment without the option of a fine is in most cases six months, but depends on the particular statute. Imprisonment under order of a court of summary jurisdiction is in the common gaol (5 Hen. IV. c. 10), *i.e.* in a local prison declared by the home secretary to be the common gaol for the county, &c., for which the court acts. The place of imprisonment during remands or in the case of youthful offenders may in certain cases be elsewhere than in a prison.

The court has power to order costs to be paid by the prosecutor or the defendant. Where the order is made on a conviction it is enforceable by imprisonment in default of payment or sufficient distress.

The extent of the local jurisdiction of justices exercising summary jurisdiction is defined by s. 46 of the act of 1879 with reference to offences committed on the boundaries of two jurisdictions or during journeys or on the sea or rivers or in harbours.

Proceedings under the Bastardy Acts are regulated by special legislation, but as to proof of service and the enforcement of orders and appeals are assimilated to convictions under the Summary Jurisdiction Acts. The same rule applies (except as to appeals) to orders made under the Summary Jurisdiction (Married Women) Act 1895, as amended by the Licensing Act 1902.

A warrant of arrest is executed by the constable or person to whom it is directed within the local jurisdiction of the issuing court; or a fresh pursuit within seven miles of its boundaries, without endorsement, in the rest of England and Wales, and in Scotland, the Channel Islands and Isle of Man after endorsement by a competent magistrate of the place where the accused is, and in Ireland by a justice of the peace or an inspector of constabulary. An English summons to a defendant or witness, except in respect of civil debts, is served in Scotland after endorsement by a competent magistrate there (Summary Jurisdiction Process Act 1881, 44 and 45 Vict. c. 24). The attendance of a witness who is in prison is obtained by writ of habeas corpus or by a secretary of state's order under the Prison Act 1898. If a witness will not attend on summons he can be brought to the court by warrant, and if he will not answer questions lawfully put to him may be sent to prison for seven days or until he sooner consents to answer.

Civil Jurisdiction.—In cases where justices have a summary civil jurisdiction, *e.g.* as to certain civil debts recoverable summarily, or to make orders to do or to abstain from doing certain acts, *e.g.* with reference to nuisances and building, the procedure differs in certain details from that in criminal cases.

1. The summons is issued on a complaint which need not be in writing nor on oath, and not on an information, and warrants of arrest cannot be issued.

2. The rules as to the evidence of the defendant and his or her spouse are the same as in civil actions.

3. The court's decision is by order and not by conviction.

4. The order if for payment of a civil debt or costs in connexion therewith is enforceable by distress and sale of the defendant's effects or by imprisonment, but only on proof that the defendant has had since the order means of paying and has refused or neglected to pay (1879, s. 35).

Proceedings for the enforcement of local rates are not affected by the Summary Jurisdiction Acts except as to the power of submitting to the High Court questions of law arising on a summons to enforce rates (*re* Allen, 1894, 2 Q.B., 924). The functions of justices as to such rates are sometimes but not quite accurately described as ministerial, for their powers of inquiry though limited are judicial and of a quasi-criminal character.

Appeal.—The orders and convictions of a court of summary jurisdiction are in many cases appealable to quarter sessions. The right to appeal is always dependent on the specific provisions of a statute. The Summary Jurisdiction Act 1879 gives a general power of appeal against an adjudication on conviction (but not on plea of guilty) to imprisonment without the option of a fine, whether as punishment for an offence or for failure to do or abstaining from doing any act, other than compliance with an order to pay money or find security or enter into recognizances or to find sureties (1879, s. 19). The procedure on the appeals is regulated and made uniform by the acts of 1879, ss. 31, 32; and 1884. These provisions are supplementary of the particular provisions of many statutes authorizing an appeal.

The decisions of courts of summary jurisdiction on points of law are generally reviewed by a case stated for the opinion of the High Court under the acts of 1857 and 1879, but are occasionally corrected by the common law remedies of *mandamus*, prohibition or *certiorari*. The application of the last-named remedy is restricted by many statutes. The court of appeal has jurisdiction to review judgments and orders of the High Court dealing with appeals, &c., from the decisions of justices in the exercise of their civil jurisdiction; but not when the subject-matter is a criminal cause or matter.

In proceedings between husband and wife for separation orders there is a special form of appeal on facts as well as law to the probate, divorce and admiralty division of the High Court (Summary Jurisdiction [Married Women] Act 1895; Licensing Act 1902, s. 5).

SCOTLAND. *Civil.*—In the Court of Session there are certain forms of summary civil proceedings by petition, *e.g.* with reference to entails, custody of children, guardians and factors of minors and lunatics, which are applications for exercise of the *nobile officium* or extraordinary jurisdiction of the court (see Mackay, *Court of Session Practice*, i. 209, ii. 353). Summary jurisdiction is given to justices of the peace as to the recovery of small debts.

Criminal and Quasi-criminal.—The only act relating to summary jurisdiction procedure common to England and Scotland is the Summary Jurisdiction Process Act 1881. Summary jurisdiction in Scotland depends chiefly upon the Summary Jurisdiction (Scotland) Acts 1864 and 1881. The acts follow, to some extent, the lines of English legislation, but the sheriff and his deputies and substitutes are included in the definition of the court, as are stipendiary magistrates (1897, c. 48). The acts also apply to proceedings before burgh courts, or burgh magistrates, and to justices of the peace where they have by other statutes power to try offences or enforce penalties. All proceedings for summary conviction or for recovery of a penalty must be by way of complaint according to one of the forms in the schedule to the act of 1864. The English summons and warrant are represented in Scotland by the warrant of citation and the warrant of apprehension. Where no punishment is fixed for a statutory offence, the court cannot sentence to more than a fine of £5 or sixty days' imprisonment, in addition to ordering caution to keep the peace. The act of 1881 adopts certain of the provisions of the English act of 1879 as to mitigation of fines, terms of imprisonment, &c., and also gives a discretion as to punishment to a sheriff trying by jury in cases where the prosecution might have been by complaint under the acts. By the Youthful Offenders Act 1901, Scottish courts of summary jurisdiction have acquired the same jurisdiction as to offences by children as was conferred on English justices in 1879. Appeals from courts of summary jurisdiction are now mainly regulated by the act of 1875 (38 and 39 Vict. c. 62), and proceed on case stated by the inferior judge. A bill was submitted to parliament in 1907 for consolidating and amending the Scottish summary procedure.

IRELAND.—In Ireland the High Court has the same summary powers in cases of contempt, and the term "court of summary jurisdiction" has the same meaning as in England (Interpretation Act 1889, s. 13 [11]), subject to the definition of the Summary Jurisdiction (Ireland) Acts, which are, as regards the Dublin metropolitan police district, the acts regulating the powers and duties of justices of the peace or of the police of that district, and as respects any other part of Ireland the Petty Sessions (Ireland) Act 1851 (14 and 15 Vict. c. 93) and any act amending the same. The acts are more extensive in their purview than the English acts, as they form in a great degree a code of substantive law as well as of procedure. By an act of 1884 the same jurisdiction was given as to offences by children as by the act of 1879 in England. Stipendiary or resident magistrates may be appointed in the place of unpaid justices under an act of 1836 (6 & 7 W. IV. c. 13). The exceptional political circumstances of Ireland have led to the conferring at different times on courts of summary jurisdiction of an authority, generally temporary, greater than that which they can exercise in Great Britain. Recent instances are the Peace Preservation Act 1881, and the Prevention of Crimes Act 1882, both expired, and the Criminal Law and Procedure (Ireland) Act 1887.

BRITISH DOMINIONS BEYOND THE SEAS.—The legislation of British possessions as to summary jurisdiction follows the lines of English legislation, but, and especially in crown colonies, there is a disposition to dispense with the jury more than under English procedure, and in most colonies stipendiary magistrates are more freely employed than unpaid justices of the peace (see British Guiana, Ord. No. 10 of 1893). Many of the colonial criminal codes include a number of offences punishable on summary conviction. The procedure closely follows English models, but has in many cases been consolidated and simplified (*e.g.* Victoria, Justices Act 1890, No. 1105; British Guiana, Ord. No. 12 of 1893). In many colonies stipendiaries and justices of the peace exercise civil jurisdiction as to matters dealt with in England by the county court (*e.g.* British Guiana, Ord. No. 11 of 1893).

UNITED STATES.—By art. iii. s. 2 of the constitution, the trial of all crimes, except in cases of impeachment, is to be by jury. By art. v. of the amendments no person can be held to answer for a capital or otherwise infamous crime unless on a presentment or indictment of a grand jury. Considerable changes have been made by state legislation in the direction of enlarging the powers of courts of summary jurisdiction.

EUROPEAN COUNTRIES.—On the continent of Europe trial of criminal cases by a bench of judges without a jury is the original and normal method, and continues except in those cases as to which under the penal and procedure codes jury trial is made necessary. In France the place of courts of summary jurisdiction is filled by *tribunaux correctionels.* (W. F. C.)

SUMMIT, a city of Union county, New Jersey, U.S.A., in the north-east of the state, about 21 m. W. of New York City. Pop. (1900) 5302, of whom 1397 were foreign-born; (1905) 6845; (1910) 7500. It is served by the Morris & Essex and the Passaic & Delaware divisions of Delaware, Lackawanna & Western railroad, and by the Rahway Valley railroad extending to Roselle, 9 m. distant. Summit is picturesquely situated on the crest of a ridge called Second Mountain, with a mean elevation of 450 ft. It is a residential suburb of New York, and attracts a number of summer residents. Among its institutions are a public library (1874), a home for blind children, the Overlook hospital and the Kent Place school (1894) for girls. On Hobart Hill there is a monument marking the site of a beacon light and a signal gun used during the War of Independence. Summit was incorporated as a township in 1869 from parts of the townships at Springfield and New Providence, and was chartered as a city in 1899.

SUMMONS (Fr. *semonce*, from *semonner* or *semondre*; Lat. *summonere, summonitio*), in English law (1) a command by a superior authority to attend at a given time or place or to do some public duty; (2) a document containing such command, and not infrequently also expressing the consequences entailed by neglect to obey. The oral summons or citation seems to have preceded the written summons in England, just as in Roman law *in jus vocatio* existed for centuries before the *libellus conventionis*. The antiquity and importance of the summons as a legal form in England is shown by the presence of the "sompnour," or summoner of the ecclesiastical court, as one of the characters in the *Canterbury Tales*, and in *The History of Sir John Oldcastle*, where the sumner is made to eat a citation issued from the bishop of Rochester's court. The term is used with reference to a demand for the attendance of a person in the high court of parliament. As regards English courts of justice it is equivalent to what in the civil and canon law and in Scots law, and in English courts deriving their procedure from those sources, is known as "citation." That term is still preserved in English ecclesiastical courts and in matrimonial causes.

It is an essential principle of justice that a court should not adjudicate upon any question without giving the parties to be affected or bound by the adjudication the opportunity of being heard and of bringing their witnesses before the court. The most usual term in English law for the process by which attendance is commanded or required is the "summons."

Civil Proceedings.—In the High Court of Justice, civil actions are begun by obtaining from the officers of the court a document known as a "writ of summons." In this document are stated the names of the parties and the nature of the claim made (which in the case of liquidated sums of money must be precise and particular). It is sealed and issued to the party suing it out, and served on the opposing party, not by an officer of the court but by an agent of the plaintiff. The tenor of the writ is to require the defendant to appear and answer the claim, and to indicate the consequences of non-appearance, viz. adjudication in default.

Many proceedings in the High Court and some in the county court are initiated by forms of summons different from the writ of summons. Of those issued in the High Court three classes merit mention:—

1. For determining interlocutory matters of practice and procedure arising in "a pending cause or matter." These are now limited as far as possible to a general summons for directions, introduced in 1883 so as to discourage frequent and expensive applications to the masters or judges of the High Court on questions of detail. These summonses are sealed and issued on application at the offices of the High Court. The matters raised are dealt with by a master or judge in chambers summarily. In matters of practice and procedure there is no appeal from a judge at chambers without leave from him or from the court of appeal.

2. For determining certain classes of questions with more despatch and less cost than is entailed by action or petition. This kind of summons is known as an "originating summons," because under it proceedings may be originated without writ for certain kinds of relief specified in the rules (R. S. C., O. 55, r. 3). The originating summons may be used in all divisions of the High Court, but is chiefly employed in the chancery division, where it to a great extent supersedes actions for the administration of trusts or of the estates of deceased persons;[1] and for the foreclosure of mortgages a similar but not identical procedure was created by the Vendor and Purchaser Act 1874, and the Conveyancing Act 1881, with reference to questions of title, &c., to real property. In the king's bench and probate divisions the originating summons is used for determining summarily questions as to property between husband and wife, or the right to custody of children, and many other matters (O. 54, rr. 4 B–4 F). The proceedings on an originating summons are conducted summarily at chambers without pleadings, and the evidence is usually written. In the chancery division where the questions raised are important the summons is adjourned into court. An appeal lies to the court of appeal from decisions on originating summonses.

The forms of summonses and the procedure thereon in civil cases in the High Court are regulated by the Rules of the Supreme Court 1883 to 1907.

3. Certain proceedings on the crown side of the king's bench division are begun by summons, *e.g.* applications for bail; and in vacation writs of habeas corpus, *mandamus*, prohibition and *certiorari* are asked for by summons as the full court is not in session. (See Crown Office Rules, 1906).

In the county courts an action is begun by plaint and summons. Two kinds of summons are in use—the ordinary summons used for every form of county court action, and the default summons, which is an optional remedy of the plaintiff in actions for debts or liquidated demands exceeding £5, and in all actions for the price or hire of goods

[1] A similar practice existed before 1883 under the powers given by 15 & 16 Vict. c. 86, but was very limited in its operation, as it applied simply to the personal estate of a deceased person.

sold or let to the defendant to be used in the way of his calling. It may also issue by leave of the judge or registrar in other cases, with the single exception that no leave can be given in claims under £5 where the claim is not for the price or hire of goods sold or let as above, if the affidavit of debt discloses that the defendant is a servant or person engaged in manual labour. The advantage of a default summons is that judgment is entered for the plaintiff without hearing unless the defendant gives notice of defence within a limited time. A default summons must as a rule be served personally on the defendant; an ordinary summons need not be served personally, but may in most cases be delivered to a person at the defendant's house or place of business. A summons is also issued to a witness in the county court. Forms of summons are given in the County Court Rules 1903. These include certain special forms used in admiralty and interpleader actions and in proceedings under the Friendly Societies Acts and the Married Women's Property Acts. Summonses issued from county courts are usually served by a bailiff of the court and not by the party suing them out.

Justices of the peace have power to issue summonses to persons accused of indictable offences, or of offences summarily punishable, for their attendance, for preliminary inquiry or summary trial according to the nature of the charge, and also to persons against whom a complaint of a civil nature within the justices' jurisdiction is made. On failure to attend on summons, attendance may be enforced by warrant; and in the case of indictable offences this is the course always adopted. The forms in use for indictable offences are scheduled to the Indictable Offences Act 1848, and those for other purposes to the Summary Jurisdiction Rules 1886 (see SUMMARY JURISDICTION). The attendance of witnesses before justices of the peace may be required by witness summons, enforced in the event of disobedience by arrest under warrant (see WITNESS).

The attendance of jurors in civil or criminal trials is required by jury summons sent by registered post.

In courts for the trial of indictable offences the attendance of the accused and of the witnesses is not secured by summons. Both ordinarily attend in obedience to recognizances entered into before justices for their attendance. In the absence of recognizances the attendance of the accused is enforced by bench warrant of the court of trial, or by justices' warrant, and that of the witnesses by writ of *subpoenâ* issued from the crown office of the High Court. Disobedience to the writ is punished as contempt of court.

Scotland.—Summons is a term confined in strictness to the beginning of an action in the Court of Session. The summons is a writ in the sovereign's name, signed by a writer to the signet, citing the defender to appear and answer the claim. The "will of the summons" is the conclusion of a writ containing the will of the sovereign or judge, charging the executive officer to cite the party whose attendance is required. It is regulated by several acts, *e.g.* The Debtors (Scotland) Act 1838 (1 & 2 Vict. c. 114) and the Court of Session (Scotland) Act 1868 (31 & 32 Vict. c. 100). A privileged summons is one where the *induciae* are shortened to six days against defenders within Scotland (Court of Session [Scotland] Act 1825, s. 53). Defects in the summons are cured by amendment or by a supplementary summons. The summons goes more into detail than the English writ of summons, though it no longer states, as it once did, the grounds of action, now stated in the condescendence and pursuer's pleas in law annexed to the summons. The form of the summons is regulated by the Court of Session (Scotland) Act 1850, s. 1 and schedule A. After the action has been set on foot by summons, the attendance of the parties and witnesses is obtained by citation. The Citation Amendment Acts 1871 and 1882 give additional facilities for the execution of citations in civil cases by means of registered letters, instead of by the old process known as "lock hole citation." In the act of 1871 the term "summons" is used to denote part of the process of inferior civil courts.

In the sheriff court an action is now begun by writ (Sheriff Courts [Scotland] Act 1907), and not as formerly by petition or summons.

In criminal cases the summons of the accused, or of witnesses, is by warrant of citation, and of jurors by citation sent by registered post (1868, c. 95, s. 10).

Ireland.—In Ireland summonses are used substantially for the same purposes and in the same manner as in England, but generally speaking under statutes and rules applying only to the Irish courts. (W. F. C.)

SUMMUM BONUM (Lat. for "highest good"), in ethics, the ideal of human attainment. The significance of the term depends upon the character of the ethical system in which it occurs. It may be viewed as a perfect moral state: as pleasure or happiness (see HEDONISM; EUDAEMONISM); as physical perfection; as wealth, and so forth. If, however, we abandon intuitional ethics, it is reasonable to argue that the term summum bonum ceases to have any real significance inasmuch as actions are not intrinsically good or bad, while the complete sceptic strives after no systematic ideal.

SUMNER, CHARLES (1811–1874), American statesman, was born in Boston, Massachusetts, on the 6th of January 1811. He graduated in 1830 at Harvard College, and in 1834 graduated at the Harvard Law School. Here, in closest intimacy with Joseph Story, he became an enthusiast in the study of jurisprudence: at the age of twenty-three he was admitted to the bar, and was contributing to the *American Jurist*, and editing law texts and Story's court decisions. What he saw of Congress during a month's visit to Washington in 1834 filled him with loathing for politics as a career, and he returned to Boston resolved to devote himself to the practice of law. The three years (1837–1840) spent in Europe were years of fruitful study and experience. He secured a ready command of French, German and Italian, equalled by no American then in public life. He formed the acquaintance of many of the leading statesmen and publicists, and secured a deep insight into continental systems of government and of jurisprudence. In England (1838) his omnivorous reading in literature, history and jurisprudence made him *persona grata* to leaders of thought. Lord Brougham declared that he "had never met with any man of Sumner's age of such extensive legal knowledge and natural legal intellect." Not till many years after Sumner's death was any other American received so intimately into the best English circles, social, political and intellectual.

In his thirtieth year, a broadly cultured cosmopolitan, Sumner returned to Boston, resolved to settle down to the practice of his profession. But gradually he devoted less of his time to practice and more to lecturing in the Harvard Law School, to editing court reports and to contributions to law journals, especially on historical and biographical lines, in which his erudition was unsurpassed. In his law practice he had disappointed himself and his friends, and he became despondent as to his future. It was in a 4th of July oration on "The True Grandeur of Nations," delivered in Boston in 1845, that he first found himself. His oration was a tremendous arraignment of war, and an impassioned appeal for freedom and for peace, and proved him an orator of the first rank. He immediately became one of the most eagerly sought orators for the lyceum and college platform. His lofty themes and stately eloquence made a profound impression, especially upon young men; his platform presence was imposing, for he was six feet and four inches in height and of massive frame; his voice was clear and of great power; his gestures unconventional and individual, but vigorous and impressive. His literary style was somewhat florid. Many of his speeches were monuments of erudition, but the wealth of detail, of allusion, and of quotation, often from the Greek and Latin, sometimes detracted from their effect.

Sumner co-operated effectively with Horace Mann for the improvement of the system of public education in Massachusetts. Prison reform and peace were other causes to which he gave ardent support. In 1847 the vigour with which Sumner denounced a Boston congressman's vote in favour of the Mexican War Bill made him the logical leader of the "Conscience Whigs," but he declined to accept their nomination for Congress. He took an active part in the organizing of the Free Soil party, in revolt at the Whigs' nomination of a slave-holding southerner for the presidency; and in 1848 was defeated as a candidate for the national House of Representatives. In 1851 control of the Massachusetts legislature was secured by the Democrats in coalition with the Free Soilers, but after filling the state offices with their own men, the Democrats refused to vote for Sumner, the Free Soilers' choice for United States senator, and urged the selection of some less radical candidate. A deadlock of more than three months ensued, finally resulting in the election (April 24) of Sumner by a majority of a single vote.

Sumner thus stepped from the lecture platform to the Senate, with no preliminary training. At first he prudently abstained from trying to force the issues in which he was interested, while he studied the temper and procedure of the Senate. In the closing hours of his first session, in spite of strenuous efforts to prevent it, Sumner delivered (Aug. 26, 1852) a speech, "Freedom national; Slavery sectional," which it was immediately felt marked a new era in American history. The conventions of both the great parties had just affirmed the finality of every provision of the Compromise of 1850. Reckless of political expediency, Sumner moved that the Fugitive Slave Act be forthwith repealed; and for more than three hours he denounced it as a violation of the constitution, an affront to the public conscience, and an offence against the divine law. The speech provoked a storm of anger in the South, but the North was heartened to find at last a leader whose courage matched his conscience. In 1856, at the very time when "border ruffians" were drawing their lines closer about the doomed town of Lawrence, Kansas, Sumner in the Senate (May 19–20) laid bare the "Crime against Kansas." He denounced the Kansas-Nebraska Bill as in every respect a swindle, and held its authors, Stephen A. Douglas and Andrew P. Butler, up to the scorn of the world as the Don Quixote and Sancho Panza of "the harlot, Slavery." Two days later (May 22) Preston S. Brooks (1819–1857), a congressman from South Carolina, suddenly confronted Sumner as he sat writing at his desk in the Senate chamber, denounced his speech as a libel upon his state and upon Butler, his relative, and before Sumner, pinioned by his desk, could make the slightest resistance, rained blow after blow upon his head, till his victim sank bleeding and unconscious upon the floor. That brutal assault cost Sumner three years of heroic struggle to restore his shattered health—years during which Massachusetts loyally re-elected him, in the belief that in the Senate chamber his vacant chair was the most eloquent pleader for free speech and resistance to slavery. Upon returning to his post, in 1859, the approaching presidential campaign of 1860 did not deter him from delivering a speech, entirely free from personal rancour, on "The Barbarism of Slavery"—to this day one of the most comprehensive and scathing indictments of American slavery ever presented.

In the critical months following Lincoln's election Sumner was an unyielding foe to every scheme of compromise. After the withdrawal of the Southern senators, Sumner was made chairman of the committee on foreign relations (March 8, 1861), a position for which he was pre-eminently fitted by his years of intimate acquaintance with European politics and statesmen. While the war was in progress his letters from Cobden and Bright, from Gladstone and the duke of Argyll, at Lincoln's request were read by Sumner to the cabinet, and formed a chief source of light as to political thought in England. In the turmoil over the "'Trent' affair," it was Sumner's word that convinced Lincoln that Mason and Slidell must be given up, and that reconciled the public to that inevitable step. Again and again Sumner used the power incident to his chairmanship to block action which threatened to embroil the United States in war with England and France. Sumner openly and boldly advocated the policy of emancipation. Lincoln described Sumner as "my idea of a bishop," and used to consult him as an embodiment of the conscience of the American people.

The war had hardly begun when Sumner put forward his theory of reconstruction: that the seceded states by their own act had "become *felo de se*," had "committed state suicide," and that their status and the conditions of their readmission to membership in the Union lay absolutely at the determination of Congress, as if they were Territories and had never been states. He resented the initiative in Reconstruction taken by Lincoln, and later by Johnson, as an encroachment upon the powers of Congress. Throughout the war Sumner had constituted himself the special champion of the negro, being the most vigorous advocate of emancipation, of enlisting the blacks in the Union army, and of the establishment of the Freedmen's Bureau. The credit or the blame for imposing equal suffrage rights for negroes upon the Southern states as a condition of Reconstruction must rest with Charles Sumner more than with any other one man. Heedless of the teachings of science as to the slow evolution of any race's capacity for self-government, he insisted on putting the ballot forthwith into the hands of even the most ignorant blacks, lest their rights be taken from them by their former masters and the fruits of the war be lost. But it must be remembered that in Sumner's plan equal suffrage was to be accompanied by free homesteads and free schools for negroes.

In the impeachment proceedings against Johnson, Sumner was one of the president's most implacable assailants. Sumner's opposition to Grant's pet scheme for the annexation of San Domingo (1870), after the president mistakenly supposed that he had secured a pledge of support, brought upon him the president's bitter resentment. Sumner had always prized highly his popularity in England, but he unhesitatingly sacrificed it in taking his stand as to the adjustment of claims against England for breaches of neutrality during the war. Sumner laid great stress upon "national claims." He held that England's according the rights of belligerents to the Confederate states had doubled the duration of the war, entailing inestimable loss. He therefore insisted that England should be required not merely to pay damages for the havoc wrought by the "Alabama" and other cruisers fitted out for Confederate service in her ports, but that, for "that other damage, immense and infinite, caused by the prolongation of the war," the withdrawal of the British flag from this hemisphere could "not be abandoned as a condition or preliminary of such a settlement as is now proposed." (At the Geneva arbitration conference these "national claims" were abandoned.) Under pressure from the president, on the ground that Sumner was no longer on speaking terms with the secretary of state, he was deposed on the 10th of March 1871 from the chairmanship of the committee on foreign relations, in which he had served with great distinction and effectiveness throughout the critical years since 1861. Whether the chief cause of this humiliation was Grant's vindictiveness at Sumner's opposition to his San Domingo project or a genuine fear that the impossible demand, which he insisted should be made upon England, would wreck the prospect of a speedy and honourable adjustment with that country, cannot be determined. In any case it was a cruel blow to a man already broken by racking illness and domestic sorrows. Sumner's last years were further saddened by the misconstruction put upon one of his most magnanimous acts. In 1872 he introduced in the Senate a resolution providing that the names of battles with fellow citizens should not be placed on the regimental colours of the United States. The Massachusetts legislature denounced this battle-flag resolution as "an insult to the loyal soldiery of the nation" and as "meeting the unqualified condemnation of the people of the Commonwealth." For more than a year all efforts—headed by the poet Whittier—to rescind that censure were without avail, but early in 1874 it was annulled. On the 10th of March, against the advice of his physician, Sumner went to the Senate—it was the day on which his colleague was to present the rescinding resolution. With those grateful words of vindication from Massachusetts in his ears Charles Sumner left the Senate chamber for the last time. That night he was stricken with an acute attack of *angina pectoris*, and on the following day he died.

Sumner was the scholar in politics. He could never be induced to suit his action to the political expediency of the moment. "The slave of principles, I call no party master," was the proud avowal with which he began his service in the Senate. For the tasks of Reconstruction he showed little aptitude. He was less a builder than a prophet. His was the first clear programme proposed in Congress for the reform of the civil service. It was his dauntless courage in denouncing compromise, in demanding the repeal of the Fugitive Slave Act, and in insisting upon emancipation, that made him the chief initiating force in the struggle that put an end to slavery.

See Sumner's *Works* (15 vols., Boston, 1870–1883), and Edward L. Pierce's *Memoir and Letters of Charles Sumner* (4 vols., Boston, 1877–1893). Briefer biographies have been written by Anna L. Dawes (New York, 1892); Moorfield Storey (Boston, 1900); and George H. Haynes (Philadelphia, 1909).

SUMNER, CHARLES RICHARD (1790–1874), English bishop, was born at Kenilworth on the 22nd of November 1790, and was educated at Eton and at Trinity College, Cambridge. He graduated B.A. in 1814, M.A. in 1817, and was ordained deacon and priest. In the two winters of 1814–1816 he ministered to the English congregation at Geneva, and from 1816 to 1821 was curate of Highclere, Hampshire. In 1820 George IV. wished to appoint him canon of Windsor, but the prime minister, Lord Liverpool, objected; Sumner received instead a royal chaplaincy and librarianship, and other preferments quickly followed, till in 1826 he was consecrated bishop of Llandaff and in 1827 bishop of Winchester. In his long administration of his latter diocese he was most energetic, tactful and munificent. Though evangelical in his views he by no means confined his patronage to that school. In 1869 he resigned his see, but continued to live at the official residence at Farnham until his death on the 15th of August 1874. He published a number of charges and sermons, and *The Ministerial Character of Christ Practically Considered* (London, 1824). He also edited and translated John Milton's *De doctrina christiana*, which was found in the State Paper office in 1823, and formed the text of Macaulay's famous essay on Milton.

See the *Life*, by his son, G. H. Sumner (1876).

SUMNER, EDWIN VOSE (1797–1863), American soldier, was born at Boston, Massachusetts, and entered the United States army in 1819. He served in the Black Hawk War and in various Indian campaigns. In 1838 he commanded the cavalry instructional establishment at Carlisle, Pennsylvania. He took part in the Mexican War as a major, and for his bravery at Molino del Rey he received the brevet rank of colonel. In 1857 he commanded an expedition against the Cheyenne Indians. At the outbreak of the Civil War, four years later, Sumner had just been promoted brigadier-general U.S.A. and sent to replace Sidney Johnston in command on the Pacific coast. He thus took no part in the first campaign of the Civil War. But in the autumn he was brought back to the East to command a division, and soon afterwards, as a major-general U.S.V., a corps in the army that was being organized by McClellan. This corps, numbered II., retained its independent existence throughout the war, and under the command of Sumner, Couch, Hancock and Humphreys it had the deserved reputation of being the best in the Union army. Sumner, who was by far the oldest of the generals in the army of the Potomac, led his corps throughout the peninsular campaign, was wounded during the Seven Days' Battle, and received the brevet of major-general U.S.A., and was again wounded in the battle of Antietam. When Burnside succeeded to the command of the army of the Potomac he grouped the corps in "grand divisions," and appointed Sumner to command the right grand division. In this capacity the old cavalry soldier took part in the disastrous battle of Fredericksburg, in which the II. corps suffered most severely. Soon afterwards, on Hooker's appointment to command the army, Sumner was relieved at his own request. He died suddenly, on the 21st of March 1863, while on his way to assume supreme command in Missouri.

SUMNER, JOHN BIRD (1780–1862), English archbishop, elder brother of Bishop Charles Sumner, was born at Kenilworth, Warwickshire, and educated at Eton and Cambridge. In 1802 he became a master at Eton, and in the following year he took orders. He was elected a fellow of Eton in 1817, and in 1818 the college presented him to the living of Maple Durham, Oxfordshire. After holding a prebendaryship of Durham for some years, he was consecrated bishop of Chester in 1828. During his episcopate many churches and schools were built in the diocese. His numerous writings were much esteemed, especially by the evangelical party, to which he belonged; the best known are his *Treatise on the Records of Creation and the Moral Attributes of the Creator* (London, 1816) and *The Evidence of Christianity derived from its Nature and Reception* (London, 1821). In 1848 he was consecrated archbishop of Canterbury, in which capacity he dealt impartially with the different church parties. In the well-known "Gorham case"[1] he came into conflict with Bishop Henry Phillpotts of Exeter (1778–1869), who accused him of supporting heresy and refused to communicate with him. He supported the Divorce Bill in parliament, but opposed the Deceased Wife's Sister Bill and the bill for removing Jewish disabilities.

[1] George Cornelius Gorham (1787–1857) was refused institution by Bishop Phillpotts because of his Calvinistic views on baptismal regeneration. The court of arches upheld the bishop, but its decision was reversed by the privy council.

SUMNER, WILLIAM GRAHAM (1840–1910), American economist, was born, of English parentage, in Paterson, New Jersey, on the 30th of October 1840. He was brought up in Hartford, Connecticut, graduated at Yale College in 1863, studied French and Hebrew in Geneva in 1863–1864 and divinity and history at Göttingen in 1864–1866, and in 1866–1869 was a tutor at Yale. He was ordained a priest of the Protestant Episcopal Church in 1869, was assistant rector of Calvary Church, New York City, and in 1870–1872 was rector of the Church of the Redeemer, Morristown, New Jersey. From 1872 to 1909, when he became professor emeritus, he was professor of political and social science at Yale. In 1909 he was president of the American Sociological Society. He died at Englewood, New Jersey, on the 12th of April 1910.

He was notable especially as an opponent of protectionism, and was a great teacher. He wrote: *History of American Currency* (1874); *Lectures on the History of Protection in the United States* (1875); *Life of Andrew Jackson* (1882), in the "American Statesmen Series"; *What Social Classes Owe to Each Other* (1883); *Collected Essays in Political and Social Sciences* (1885); *Protectionism* (1885); *Alexander Hamilton* (1891), and *Robert Morris* (1891), in the "Makers of America Series"; *The Financier and Finances of the American Revolution* (2 vols., 1891); *A History of Banking in the United States* (1896); and *Folkways: a Study of the Sociological Importance of Usages, Manners, Customs, Mores and Morals* (1907), a valuable sociological summary.

SUMPTER, a pack-horse or mule, a beast for carrying burdens, particularly for military purposes. There were two words once in use, which in sense, if not in form, have coalesced. These are "sommer" or "summer" and "sumpter." The first comes through the Old French *sommier*, a pack-horse, the other through *sommetier*, a pack-horse driver. Both come ultimately from Late Lat. *salma*, from *sagma*, a pack, burden, Old French *somme*, *saume*; Greek *σάγμα*, burden, *σάττειν*, to load. "Sumpter" in the sense of a driver of a pack-horse is rare, and the word is always joined with another explanatory word.

SUMPTUARY LAWS (from Lat. *sumptuarius*, belonging to cost or expense, *sumptus*), those laws intended to limit or regulate the private expenditure of the citizens of a community. They may be dictated by political, or economic, or moral considerations. They have existed both in ancient and in modern states. In Greece, it was amongst the Dorian races, whose temper was austere and rigid, that they most prevailed. All the inhabitants of Laconia were forbidden to attend drinking entertainments, nor could a Lacedaemonian possess a house or furniture which was the work of more elaborate implements than the axe and saw. Among the Spartans proper simple and frugal habits of life were secured rather by the institution of the *pheidilia* (public meals) than by special enactments. The possession of gold or silver was interdicted to the citizens of Sparta, and the use of iron money alone was permitted by the Lycurgean legislation. "Even in the cities which had early departed from the Doric customs," says K. O. Müller, "there were frequent and strict prohibitions against expensiveness of female attire, prostitutes alone being wisely excepted." In the Locrian code of Zaleucus citizens were forbidden to drink undiluted wine. The Solonian sumptuary enactments were directed principally against the extravagance of female apparel and dowries of excessive amount; costly banquets also were forbidden, and expensive funeral solemnities. The Pythagoreans in Magna Graecia not only protested against the luxury of their time but encouraged legislation with a view to restraining it.

At Rome the system of sumptuary edicts and enactments was largely developed, whilst the objects of such legislation were concurrently sought to be attained through the exercise of the censorial power. The code of the Twelve Tables contained provisions limiting the expenditure on funerals. The most important sumptuary laws of the Roman commonwealth are the following:—

(1) The Oppian law, 215 B.C., provided that no woman should possess more than half an ounce of gold, or wear a dress of different colours, or ride in a carriage in the city or within a mile of it except on occasions of public religious ceremonies. This law, which had been partly dictated by the financial necessities of the conflict with Hannibal, was repealed twenty years later, against the advice of Cato. Livy (xxxiv. 1–8) gives an interesting account of the commotion excited by the proposal of the repeal, and of the exertions of the Roman women against the law, which almost amounted to a female *émeute.* (2) The Orchian law, 187 B.C., limited the number of guests at entertainments. An attempt being made to repeal this law, Cato offered strong opposition and delivered a speech on the subject, of which some fragments have been preserved. (3) The Fannian law, 161 B.C., limited the sums to be spent on entertainments; it provided amongst other things that no fowl should be served but a single hen, and that not fattened. (4) The Didian law, 143 B.C., extended to the whole of Italy the provisions of the Fannian law, and made the guests as well as the givers of entertainments at which the law was violated liable to the penalties. After a considerable interval, Sulla anew directed legislation against the luxury of the table and also limited the cost of funerals and of sepulchral monuments. We are told that he violated his own law as to funerals when burying his wife Metella, and also his law on entertainments when seeking to forget his grief for her loss in extravagant drinking and feasting (Plut. *Sull.* 35). Julius Caesar, in the capacity of *praefectus moribus*, after the African War re-enacted some of the sumptuary laws which had fallen into neglect; Cicero implies (*Ep. ad Att.* xiii. 7) that in Caesar's absence his legislation of this kind was not attended to. Suetonius tells us that Caesar had officers stationed in the market-places to seize such provisions as were forbidden by law, and sent lictors and soldiers to feasts to remove all illegal eatables (*Jul.* 43). Augustus fixed anew the expense to be incurred in entertainments on ordinary and festal days. Tiberius also sought to check inordinate expense on banquets, and a decree of the senate was passed in his reign forbidding the use of gold vases except in sacred rites, and prohibiting the wearing of silk garments by men. But it appears from Tacitus (*Ann.* iii. 5, where a speech is put into his mouth very much in the spirit of Horace's "Quid leges sine moribus vanae proficiunt?") that he looked more to the improvement of manners than to direct legislative action for the restriction of luxury. Suetonius mentions some regulations made by Nero, and we hear of further legislation of this kind by Hadrian and later emperors. In the time of Tertullian the sumptuary laws appear to have been things of the past (*Apol.* c. vi.).

In modern times the first important sumptuary legislation was: in Italy that of Frederick II.; in Aragon that of James I., in 1234; in France that of Philip IV.; in England that of Edward II. and Edward III. In 1294 Philip IV. made provisions as to the dress and the table expenditure of the several orders of men in his kingdom. Charles V. of France forbade the use of long-pointed shoes, a fashion against which popes and councils had protested in vain. Under later kings the use of gold and silver embroidery, silk stuffs and fine linen wares was restricted —at first moral and afterwards economic motives being put forward, the latter especially from the rise of the mercantile theory. In England we hear much from the writers of the 14th century of the extravagance of dress at that period. They remark both on the great splendour and expensiveness of the apparel of the higher orders and on the fantastic and deforming fashions adopted by persons of all ranks. The parliament held at Westminster in 1363 made laws (37 Edw. III. c. 8–14) to restrain this undue expenditure and to regulate the dress of the several classes of the people. These statutes were repealed in the following year, but similar ones were passed again in the same reign. They seem, however, to have had little effect, for in the reign of Richard II. the same excesses prevailed, apparently in a still greater degree. Another statute was passed in the year 1463 (3 Edw. IV. c. 5) for the regulation of the dress of persons of all ranks. In this it was stated that "the commons of the realm, as well men as women, wear excessive and inordinate apparel to the great displeasure of God, the enriching of strange realms, and the destruction of this realm." An act of 1444 had previously regulated the clothing, when it formed part of the wages, of servants employed in husbandry: a bailiff or overseer was to have an allowance of 5s. a year for his clothing, a hind or principal servant 4s., and an ordinary servant 3s. 4d.—sums equivalent respectively to 50s., 40s. and 33s. 4d. of our money (Henry). Already in the reign of Edward II. a proclamation had been issued against the "outrageous and excessive multitude of meats and dishes which the great men of the kingdom had used, and still used, in their castles," as well as "persons of inferior rank imitating their example, beyond what their stations required and their circumstances could afford"; and the rule was laid down that the great men should have but two courses of flesh meat served up to their tables, and on fish days two courses of fish, each course consisting of but two kinds. In 1336 Edward III. attempted also to legislate against luxurious living, and in 1363, at the same time when costumes were regulated, it was enacted that the servants of gentlemen, merchants and artificers should have only one meal of flesh or fish in the day, and that their other food should consist of milk, butter and cheese. Similar acts to those above mentioned were passed in Scotland also. In 1433 (*temp.* James I.), by an act of a parliament which sat at Perth, the manner of living of all orders in Scotland was prescribed, and in particular the use of pies and baked meats, which had been only lately introduced into the country, was forbidden to all under the rank of baron. In 1457 (*temp.* James II.) an act was passed against "sumptuous cleithing." A Scottish sumptuary law of 1621 was the last of the kind in Great Britain.

In Japan sumptuary laws have been passed with a frequency and minuteness of scope such as has no parallel in the history of the western world. At the beginning of the 11th century we find an Imperial edict regulating the size of a house and even imposing restrictions as to the materials of which it is to be built. But it was during the Tokugawa period that sumptuary laws and regulations were passed in the most bewildering profusion; every detail of a man's life was regulated down to the least particular—from the wearing of a beard or the dressing of the hair down to the cost of his wife's hairpins or the price of his child's doll.[1]

A. Ferguson and others have pointed out that "luxury" is a term of relative import and that all luxuries do not deserve to be discouraged. Roscher has called attention to the fact that the nature of the prevalent luxury changes with the stage of social development. He endeavours to show that there are three periods in the history of luxury—one in which it is coarse and profuse; a second in which it aims mainly at comfort and elegance; and a third, proper to periods of decadence, in which it is perverted to vicious and unnatural ends. The second of these began, in modern times, with the emergence of the Western nations from the medieval period, and in the ancient communities at epochs of similar transition. Roscher holds that the sumptuary legislation which regularly appears at the opening of this stage was then useful as promoting the reformation of habits. He remarks that the contemporary formation of strong governments, disposed from the consciousness of their strength to interfere with the lives of their subjects, tended to encourage such legislation, as did also the jealousy felt by the hitherto dominant ranks of the rising wealth of the citizen classes, who are apt to imitate the conduct of their superiors. It is certainly desirable that habits of wasteful expenditure and frequent and wanton changes of fashion should be discouraged. But such action belongs more properly to the spiritual than to the temporal power. In ancient, especially Roman, life, when there was a confusion of the two powers in the state system, sumptuary legislation was more natural than in the modern world, in which those powers have been in general really, though imperfectly, separated. Political economists are practically unanimous in their reprobation of the policy of legislative compulsion in these matters. In a well-known passage Adam Smith protests against the "impertinence and presumption of kings and ministers in pretending to watch over the economy of private people and to restrain their expense, being themselves always and without any exception the greatest spendthrifts in the society." Yet he does not seem to have been averse from all attempts to influence through taxation the expenditure of the humbler classes. The modern taxes on carriages, coats of arms, male servants, playing cards, &c., ought perhaps not to be regarded as resting on the principle of sumptuary laws, but only as means of proportioning taxation to the capacity of bearing the burden.

The *loci classici* on Roman sumptuary laws are Gellius, *Noctes atticae*, ii. 24, and Macrobius, *Saturn.* iii. 17. For Great Britain see Henry of Huntingdon, *Historia Anglorum* ("Rolls Series," ed. T. Arnold, 1879); W. Cunningham, *Growth of English Industry and*

SUMTER, THOMAS (1736–1832), American soldier, was born in Hanover county, Virginia, on the 14th of July 1736. He served in the Virginia militia during the French and Indian War and was present at Braddock's defeat (1755). Some time after 1762 he removed to South Carolina. He is best known for his service during the War of Independence, but he saw little active service until after the fall of Charleston in May 1780. In July 1780 he became a brigadier-general of state troops. During the remainder of the war he carried on a partisan campaign, and earned the sobriquet of the "Gamecock." He failed in an attack upon Rocky Mount (Chester county) on the 1st of August 1780, but on the 6th defeated 500 Loyalists and regulars at Hanging Rock (Lancaster county), and on the 15th intercepted and defeated a convoy with stores between Charleston and Camden. His own regiment, however, was almost annihilated by Lieut.-Colonel Banastre Tarleton (1754–1833) at Fishing Creek (Chester county) on the 18th. A new force was soon recruited, with which he defeated Major James Wemys at Fishdam (Union county) on the night of the 8th–9th of November, and repulsed Tarleton's attack at Blackstock (Union county) on the 20th, when he was wounded. In January 1781 Congress formally thanked him for his services. He was a member of the state convention which ratified the Federal constitution for South Carolina in 1788, he himself opposing that instrument; of the national House of Representatives in 1789–1793 and again in 1797–1801, and of the United States Senate from 1801 to 1810. At the time of his death at South Mount, South Carolina, on the 1st of June 1832, he was the last surviving general officer of the War of Independence.

See Edward McCrady, *The History of South Carolina in the Revolution* (2 vols., New York, 1901–1902).

SUMTER, a city and the county-seat of Sumter county, South Carolina, U.S.A., 42 m. by rail E. by S. of Columbia. Pop. (1900) 5673 (3160 negroes); (1910) 8109. Sumter is served by several divisions of the Atlantic Coast line and by the Southern railways. It is the seat of St Joseph's Academy (Roman Catholic) for girls. The region produces tobacco, vegetables and cotton, and there are various manufactories in the city. Sumter was founded in 1800 and was named in honour of General Thomas Sumter; it was first chartered as a city in 1887.

SUMY, a town of Little Russia, in the government of Kharkov, 122 m. by rail N.W. of the city of Kharkov, founded in 1658. Pop. (1900), 28,519. It is an important centre for the trade of Great Russia with Little Russia—cattle and corn being sent to the north in exchange for manufactured and grocery wares. It has important sugar manufacture, and a technical school.

SUN (O. Eng. *sunne*, Ger. *sonne*. Fr. *soleil*, Lat. *sol*, Gr. ἥλιος, from which comes *helio-* in various English compounds), the name of the central body of the solar system, the luminous orb from which the earth receives light and heat; (see SUNSHINE); hence by analogy other heavenly bodies which form the centre of systems are called suns.

To understand the phenomena of the sun, we should reproduce them upon the earth; but this is clearly impossible since they take place at temperatures which volatilize all known substances. Hence our only guides are such general laws of mechanics and physics as we can hardly believe any circumstances will falsify. But it must be remembered that these require extrapolation from experience sometimes sufficiently remote, and it is possible they may lead to statements that are obscure, if not contradictory. The body of the sun must consist of uncombined gases; at the surface the temperature is some 2000° C. above the boiling point of carbon, and a little way within the body it may probably exceed the critical point at which increase of pressure can produce the liquid state in any substance. But as the mean density exceeds that of water, and probably falls but little from the centre to the surface, these gases are gases only in the sense that if the pressure of neighbouring and outward parts gravitating towards the centre were relaxed, they would expand explosively, as we see happening in the eruptive prominences. They have lost completely the gaseous characteristic of producing a line spectrum, and radiate like incandescent solids. The surface region which yields a continuous spectrum is called the *photosphere*; it possesses optically a sharp boundary, which is generally a perfect sphere, but shows occasionally at the rim slight depressions or more rarely elevations. Enclosing the photosphere is a truly gaseous envelope which is called the *chromosphere*, and which shows a spectrum of bright lines when we can isolate its emission from that of the photosphere. This envelope is also sharply defined, but its normal appearance is compared to the serrations which blades of grass show on the skyline of a hill, and it is disturbed by the outbursts, called prominences, of which details are given below. Outside this again is an envelope of matter of enormous extent and extreme tenuity, whether gaseous or partly minute liquid or solid drops, which is called the *corona*. It has no sharp boundary, its brightness diminishes rapidly as we recede from the limb, and such structure as it shows consists of long streaks or filaments extending outwards from the limb in broad curved sweeps. Finally there is the envelope of still vaster extent and of unknown constitution which gives the *zodiacal light* (*q.v.*); its greatest extent is along the ecliptic, but it can also be certainly traced for 35° in a perpendicular direction. The lower gaseous cloaks absorb a large part of the light admitted by the photosphere, and especially at the limb and for the more refrangible rays the loss of intensity is very marked.

General Appearance of Photosphere.

In the instants when a sharp image of the photosphere is seen or photographed, it shows a granulated appearance like white flakes strewed fairly evenly upon a dark ground. The figs. 1, 2, 3, 4 (plate) show enlargements from photographs by Hansky at Pulkowa (June 25, 1905); they are separated by intervals from 25 to 80 seconds, and he has succeeded in showing identity in many of the granules, or more properly, clouds represented. Thus they exhibit at once general appearance and its changes. The diameters range from 400 m. or less up to 1200 m., and the speeds relative to the spot range up to 2 or 3 m. per second. M. Hansky believes these motions may be the consequences of matter rising from below and thrusting the surface groups aside. Usually the changes are such that it is impossible even to recognize the formations in successive photographs. Besides granulations the sun's disk shows, as a rule, one or more spots or groups of spots. Each spot shows with more or less completeness a ring-shaped penumbra enclosing a darker umbra; the umbra, which looks black beside the photosphere, is actually about as brilliant as limelight. In the neighbourhood surrounding the penumbra the granules appear to be packed more closely, forming brilliant patches called *faculae*. In the shape of a spot there is neither rule nor permanence, though those that are nearly circular seem to resist change better than the others. They arise from combinations of smaller spots, or from nothing, in a short period, say a day. They are never wholly quiescent. Bridges, more brilliant than the rest of the photosphere, form across them, and they may divide into two parts which separate from one another with great velocity. The largest spots are easily seen by the naked eye, if the brilliancy of the disk is veiled; the umbra may be many—ten or more—diameters of the earth in breadth. The length of their life is difficult to assign, because there is some tendency for a new group to arise where an old one has disappeared; but one is recorded which appeared in the same place for eighteen months; the average is perhaps two months. They are carried across the disk by the sun's rotation, partaking in the equatorial acceleration; they also show marked displacements of their own, whether with, or relative to, the neighbouring photosphere does not appear; at the beginning of their life they usually outrun the average daily rotation appropriate to their latitude. Spots are rarely found on the equator, or more than 35° N. or S. of it, and at 45° are practically unknown. Their occurrence within these zones follows statistically a uniform law (see AURORA). Other information about the spots is given below, in connexion with their spectra. It may be said that nothing definite has been established as to what they are. The statement known as A. Wilson's theory (1774), that they are hollows in the photosphere, long supposed to be proved by perspective effects as the spot approached the limb, is discredited by F. Howlett's careful drawings, which, however, do not establish the contrary. To draw a trustworthy conclusion it is necessary that the spot should be quiescent, show a well-developed and fairly symmetrical penumbra, and be observed near the limb and also near the centre, and these conditions are satisfied in so few cases as to withdraw all statistical force from the conclusion. Figs. 5, 6, 7, 8 (plate) are reproductions of the Greenwich photographs of the sun from the 30th of January to the 8th of February 1905. The first, taken alone, might seem to bear out Wilson's theory, but the others show that the penumbra is really very unsymmetrical and much broader on the side towards the limb, apart from anything which perspective may have to say. The photosphere does not rotate in one piece, lower latitudes outrunning higher. This was discovered by R. C. Carrington from observations of the spots, extending from 1853 to 1861, from which he determined also the position of the sun's axis. But conclusions from the spots are full of anomalies. E. W. Maunder and Mrs Maunder found that different spots in the same zone differ more than do the means for different zones, while a long-lived spot settles down to give more consistent results than are furnished by spots of one apparition. In the span of two complete sunspot periods no evidence was found of periodic or other change with lapse of time. The problem still awaits complete discussion. The irregularities incidental to use of the spots are escaped by comparing the relative Doppler displacements of the same spectral line as given by the receding and advancing limbs of the sun. The observation is a delicate one, and was first successfully handled by N. C. Dunér in 1890. But his determinations, repeated recently (*Acta upsal.* IV. vol. i., 1907) as well as those of J. Halm at Edinburgh (*Ast. Nach.* vol. 173, 1907), are superseded by a photographic treatment of the problem by W. S. Adams (*Astrophys. Journ.*, xxvi., 1907).

Rotation of the Photosphere.

The diagram (fig. 9) shows Adams's value for the angular velocity ξ for different latitudes ϕ, the dots representing the actual observations. Fig. 10 shows the consequent distortion of a set of meridians after one revolution (at lat. 30°). An important feature added to the discussion by Adams is the different behaviour of spectral lines

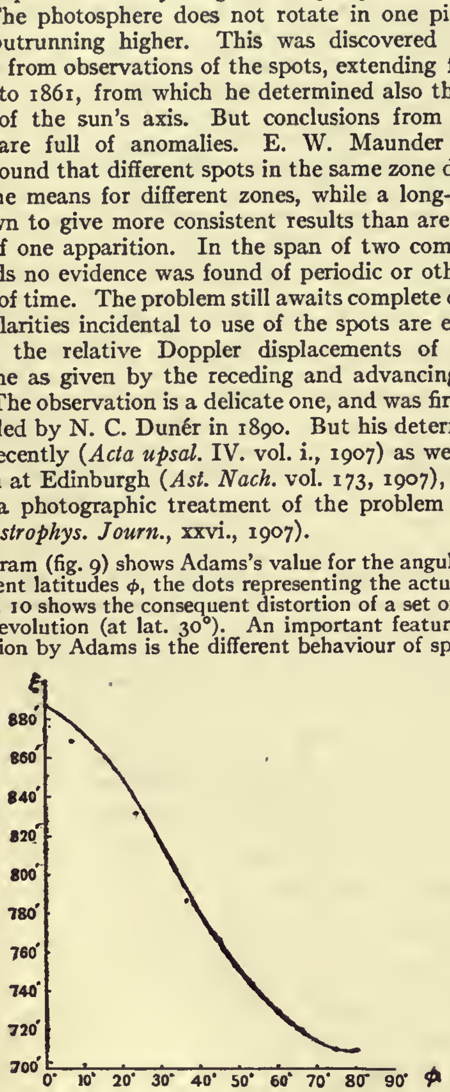

FIG. 9.

which are believed to originate at different levels. The data given above refer to the mean reversing layer. Lines of lanthanum and carbon which are believed to belong to a low level showed systematically smaller angular velocity than the average. This promises to be a fertile field for future inquiry. Pending more conclusive evidence from the spectroscope, the interpretation of the peculiar surface rotation of the sun appears to be that the central parts of the body are rotating faster than those outside them; for if such were the case the observed phenomenon would arise. For consider first a frictionless fluid. The equations of surfaces of equal angular motion would be of the form $r = \mathrm{R}\ (1 - \epsilon \cos^2\theta)$, where ϵ is proportional to the square of the angular motion, supposed small, and R increases as ϵ diminishes. Consider the traces these surfaces cut on any sphere $r = a$: we have $d\epsilon/d\theta = 2\epsilon \sin\theta \cos\theta / \{\cos^2\theta - a\mathrm{R}^{-2} d\mathrm{R}/d\epsilon\}$, which is positive and has a maximum in the middle latitudes; so that, proceeding from the pole to the equator along any meridian, the angular velocity would continually increase, at a rate which was greatest in the middle latitudes. This is exactly what the observations show. Now if this state be supposed established in a frictionless fluid, the consideration of internal friction would simply extend the characteristics found at any spot to the neighbourhood, and therefore if the boundary were a sphere and so for a frictionless fluid an exception, it would cease to be an exception when we allow for viscosity. But this theory gives no clue to the results relating to hydrogen, which belongs to a high level, and which Adams has shown to move with an angular velocity decidedly greater than the equatorial angular velocity below it, and not to show any sign of falling off towards the poles.

FIG. 10.

Mechanical State Internally.

It is useful to form a conception of the mechanical state within the sun's body. Its temperature must be dominated directly or indirectly by the surface radiation, and since the matter is gaseous and so open to redistribution, the same is true of density and pressure. It is true that within the body radiations must be stifled within a short distance of their source; none the less, they will determine a temperature gradient, falling from the centre to the borders, though for the most part falling very slowly, and we may ask what relative temperatures in different parts would maintain themselves if once established. Stefan's law of radiation according to the fourth power of the temperature is too difficult to pursue, but if we are content with cognate results we can follow them out mathematically in a hypothetical law of the first power. We then find that the density would increase as we go outwards, at first slowly, but finally with extreme rapidity, the last tenth of the radius comprising half the mass. The radiation from such a body would be practically nil, no matter how hot the centre was. Of course such a state would be statically unstable. It would never get established because currents would arise to exchange the positions of the hotter, less dense, inner parts and the cooler, more dense, outer ones. By this interchange the inner parts would be opened out and the total radiation raised. Since the only cause for these convection currents is the statical instability produced by radiation, and the rapid stifling of radiations within the body produces there a temperature gradient falling very slowly, they would be for the most part extremely slight. Only near the surface would they become violent, and only there would there be a rapid fall of temperature and density. Through the main body these would remain nearly constant. Indeed it seems that, in the final distribution of density throughout the part which is not subject to violent convection currents, it must increase slightly from the centre outwards, since the currents would cease altogether as soon as a uniform state was restored. In the outer strata a different state must prevail. Rapidly falling temperature must (and visibly does) produce furious motions which wholly outrun mere restoration of statical balance. Portions change places so rapidly and so continually, that we may take it, where any average is reached, the energy is so distributed that there is neither gain nor loss when such a change occurs. This is the law of convective equilibrium. But in the sun's atmosphere gravitation alone is a misleading guide. Convective equilibrium, which depends upon it, gives far too steep a temperature gradient, for it yields a temperature of 6000° only 200 m. within the free surface, whereas the chromosphere is of an average thickness of 5000 m., and attains that temperature only at its base. Probably the factor which thus diminishes the effective

Observer: E. W. Maunder. Instrument, Thompson Photoheliograph. Focal length, 9 ft. Aperture, 9 in.

condensing power of gravitation at the sun's borders is the pressure of radiation.

The radiations from the sun must be considered in two parts, corresponding respectively to the continuous spectrum and the line-spectrum. The latter is considered below; it is indicative of the chemical elements from which the lines can proceed, and its state at the time of emission; the former is indicative only of the rate of loss of energy from the sun by radiation, and is inwoven with a remarkable group of physical theory and experiment, known as the theory of the black body, or as black radiation. The "black body" is an ideal body with surface so constituted as to reflect no part of any radiations that fall upon it; in the case of such a body Kirchhoff and Balfour Stewart showed that unless energy were to be lost the rate of emission and absorption must be in fixed ratio for each specific wave-length.

"The Black Body."

The name has no reference to the appearance of the body to the eye; when emitting energy, its radiations will be of all wave-lengths, and if intense enough will appeal to the eye as luminous between about wave-lengths 7600 and 4000 tenth-metres; this intensity is a question of temperature, and as it is exquisitely inappropriate to speak of the bulk of the solar radiations as black, the writer will speak instead of amorphous radiations from an ideal radiator. The ideal radiator is realized within any closed cavity, the walls of which are maintained at a definite temperature. The space within is filled with radiations corresponding to this temperature, and these attain a certain equilibrium which permits the energy of radiation to be spoken of as a whole, as a scalar quantity, without express reference to the propagation or interference of the waves of which it is composed. It is then found both by experiment and by thermodynamic theory that in these amorphous radiations there is for each temperature a definite distribution of the energy over the spectrum according to a law which may be expressed by $\theta^5\phi(\theta\lambda)d\lambda$, between the wave-lengths λ, $\lambda+d\lambda$; and as to the form of the function ϕ, Planck has shown (*Sitzungsber. Berlin Akad.* 544) that an intelligible theory can be given which leads to the form $\phi(\theta\lambda)=c_1/\{exp(c_2/\lambda\theta)-1\}$, a form which agrees in a satisfactory way with all the experiments. Fig. 11 shows the resulting distribution of energy. The enclosed area for each temperature represents the total emission of energy for that temperature, the abscissae are the wave-lengths, and the ordinates the corresponding intensities of emission for that wave-length. It will be seen that the maximum ordinates lie upon the curve $\lambda\theta=$ constant dotted in the figure, and so, as the temperature of the ideal body rises, the wave-length of most intense radiation shifts from the infra-red towards the luminous part of the spectrum. When we speak of the sun's radiation as a whole, it is assumed that it is of the character of the radiations from an ideal radiator at an appropriate temperature.

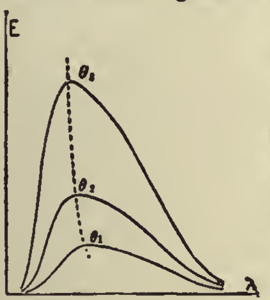

FIG. 11.

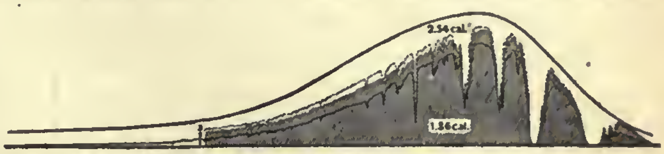
The Solar Constant.

The first adequate determination of the character as well as amount of solar radiation was made by S. P. Langley in 1893 at Mount Whitney in California (14,000 ft.), with the bolometer, an exceedingly sensitive instrument which he invented, and which enabled him to feel his way thermally over the whole spectrum, noting all the chief Fraunhofer lines and bands, which were shown by sharp serrations, or more prolonged depressions of the curve which gave the emissions, and discovering the lines and bands of the invisible ultra-red portion. The bolograph thus obtained must be cleared of the absorption of the earth's atmosphere, and that of the transmitting apparatus—a spectroscope and siderostat. The first in itself requires an elaborate study. The first essential is an elevated observatory; the next is a long series of bolographs taken at different times of the year and of the day, to examine the effect of interposing different thicknesses of air and its variation in transparency (chiefly due to water vapour). It is found that atmospheric absorption is generally greater in summer than in winter, a difference of 20% being found between March and August; morning hours show a rapid and often irregular increase of transparency, culminating shortly after noon, after which the diminution is slow and comparatively regular.

The resulting allowances and conclusion are illustrated in fig. 12, taken from an article by Langley in the *Astrophysical Journal* (1903), xvii. 2. The integrated emission of energy is given by the area of the outer smoothed curve (4), and the conclusion from this one bolograph is that the "solar constant" is 2·54 calories. The meaning of this statement is that, arguing away the earth's atmosphere, which wastes about one-half what is received, a square centimetre, exposed perpendicularly to the sun's rays, would receive sufficient energy per minute to raise 2·54 grams of water 1° C. Langley's general determination of the constant was greater than this—3·0 to 3·5 calories; more recently C. G. Abbot at Mount Wilson, with instruments and methods in which Langley's experience is embodied, has reduced it greatly, having proved that one of Langley's corrections was erroneously applied. The results vary between 1·89 and 2·22, and the variation appears to be solar, not terrestrial. Taking the value at 2·1 the earth is therefore receiving energy at the rate of 1·47 kilowatts per square metre, or 1·70 horse-power per square yard. The corresponding intensity at the sun's surface is $4{\cdot}62\times10^4$ as great, or $6{\cdot}79\times10^4$ kilowatts per square metre $=7{\cdot}88\times10^4$ horse-power per square yard—enough to melt a thickness of 13·3 metres (=39·6 ft.) of ice, or to vaporize 1·81 metres (=5·92 ft.) of water per minute.



(From *Astrophysical Journal*, xvii. 2, by permission of the University of Chicago Press.)

FIG. 12.

Temperature of the Sun.

If we assume that the bolograph of solar energy is simply a graph of amorphous radiation from an ideal radiator, so that the constants c_1, c_2, of Planck's formula determined terrestrially apply to it, the hyperbola of maximum intensity is $\lambda\theta=2{\cdot}921\times10^7$; and as the sun's maximum intensity occurs for about $\lambda=4900$, we find the absolute temperature to be 5960° abs. If we calculate from the total energy emitted, and not from the position of maximum intensity, the same result is obtained within a few degrees. But to call this the temperature of the sun's surface is a convention, which sets aside some material factors. We may ask first whether the matter of which the surface is composed is such as to give an ideal radiator; it is impossible to answer this, but even if we admit a departure as great as the greatest known terrestrial exception, the estimated temperature is diminished only some 10%. A second question relates to the boundaries. The theory refers to radiation homogeneous at all points within a single closed boundary maintained at uniform temperature; in the actual case we have a double boundary, one the sun's surface, and the other infinitely remote, or say, non-existent, and at zero temperature; and it is assumed that the density of radiation in the free space varies inversely as the squares of the distance from the sun. Though there is no experiment behind this assumption it can hardly lead to error.

A third question is more difficult. The temperature gradient at the confines of the photosphere must certainly ascend sharply at first. When we say the sun's temperature is 6000°, of what level are we speaking? The fact is that radiation is not a superficial phenomenon but a molar one, and Stefan's law, exact though it be, is not an ultimate theory but only a convenient halting-place, and the radiations of two bodies can only be compared by it when their surfaces are similar in a specific way. One characteristic of such surfaces is fixity, which has no trace of parallel in the sun. The confines of the sun are visibly in a state of turmoil, for which a sufficient cause can be assigned in the relative readiness with which the outer portions part with heat to space, and so condensing produce a state of static instability, so that the outer surface of the sun in place of being fixed is continually circulating, portions at high temperatures rising rapidly from the depths to positions where they will part rapidly with their heat, and then, whether perceived or not, descending again. It is clear that at least a considerable part of the solar radiations comes from a more or less diffuse atmosphere. With the help of theory and observation the part played by this atmosphere is tolerably precise. Its absorptive effects upon the radiations of the inner photosphere can be readily traced progressively from the centre to the rim of the sun's disk, and it has been measured as a whole by Langley, W. E. Wilson and others, and for each separate wave-length by F. W. Very (*Astrophys. Journ.*, vol. xvi.). The entries in the table on following page express the reduction of intensity for different wave-lengths λ, when the slit is set at distances $\gamma\times$radius from the centre of the disk.

Building upon these results A. Schuster has shown (*Astrophys. Journ.*, vol. xvi.) that, if for the sake of argument the solar atmosphere be taken as homogeneous in temperature and quality, forming a sheet which itself radiates as well as absorbs, the radiation which an unshielded ideal radiator at 6000° would give is represented well, both in sum and in the distribution of intensity with respect to wave-length, by another ideal radiator—now the actual body of the sun—at about 6700°, shielded by an atmosphere at an average temperature of 5500°, and that such an atmosphere itself provides about 0·3 of the total radiations that reach us.

In connexion with this subject it may be mentioned that the highest measured temperature produced terrestrially, that of the arc, is about 3500° to 4000° abs.

Age of the Sun. The energy which the sun pours out into space is, so far as we know, and except for the minute fraction intercepted by the disks of the planets ($\frac{1}{120000000}$) absolutely lost for the purposes of further mechanical effect. The amount is such that, supposing the average specific heat of the sun's body as high as that of water, there would result a general fall of temperature of 2·0° to 2·5° C. in the lapse of each year. Hence, if no other agency is invoked, at an epoch say $x \times 1000$ years ago, the sun's heat would have been greater than now by the factor $1+x/3n$, where $n \times 6000°$ is taken for the sun's present mean temperature. It seems possible that n is not a large number, and if we take x equal, say, to 200, we come to the most recent estimate—the astronomical—of the date of the earth's glacial epoch, when the sun's radiation was certainly not much more than it is now, while this factor would differ materially from unity. Hence loss does not go on without regeneration, and we are apparently at a stage when there is an approximate balance between them. It is in fact an impossibility that loss should go on without regeneration, for if any part of the sun's body loses heat, it will be unable to support the pressure of neighbouring parts upon it; it will therefore be compressed, in a general sense towards the sun's centre, the velocities of its molecules will rise, and its temperature will again tend upwards. In consequence of the radiation of heat the whole body will be more condensed than before, but whether it is hotter or colder than before will depend on whether the contraction set up is more or less than enough to restore an exact balance. If we are dealing with comparatively recent periods there is no evidence of progressive change, but if we go to remote epochs and suppose the sun to have once been diffused in a nebulous state, it is clear that its shrinkage, in spite of radiation, has left it hotter, so that the shrinkage has outrun what would suffice to maintain its radiation. It is equally clear that there is a point beyond which contraction cannot go, and thereafter, if not before, the body will begin to grow colder. There is thus a turning-point in the life of every star. The movement towards contraction and consequent rise of temperature which radiation sets up, like other motions, overruns the equilibrium-point, only however by a minute amount; the accumulated excesses from all past time now stored in the sun would maintain its radiations at their present rate for $n \times 3000$ years, that is, for a few thousand years only.

There is a superior limit to the quantity of energy which can be derived from contraction. If we suppose the sun's mass once existed in a state of extreme diffusion, the energy yielded by collecting it into its present compass would not suffice to maintain its present rate of radiation for more than 17,000,000 years in the past; nor if its mean density were ultimately to rise to eight times its present amount, for more than the same period in the future. This supposes the present density nearly uniform; if it is not uniform, any amount added to the former period is subtracted from the latter. A contraction of 0·2″ or 90 m. in the sun's radius would maintain the present emission for 3500 years. Such a rate of change would be quite insensible, and we can affirm that for recent times there is no reason to look for any other factor than contraction; but if we consider the remote past it is a different matter. We know nothing quantitatively of the radiations from a nebulous body: and it is quite possible that the loss of radiant energy in this early stage was very small; but it is at least as certain as any other physical inference that 17,000,000 years ago the earth itself was of its present dimensions, a comparatively old body with sea and living creatures upon it, and it is impossible to believe that the sun's radiations were wholly different; but, if they were not, they have been maintained from some other source than contraction.

The fall of meteoric matter into the sun must be a certain source of energy; if considerable, this external supply would retard the sun's contraction and so increase its estimated age, but to bring about a reconciliation with geological theory, very nearly the whole amount must be thus supplied. It is easy to calculate that this would be produced by an annual fall of matter equal to one nineteen millionth of the sun's mass, which would make an envelope eight metres thick, at the sun's mean density; this would be collected during the year from a spherical space extending beyond the orbit of Jupiter. The earth would intercept an amount of it proportional to the solid angle it subtends at the sun; that is to say, it would receive a deposit of meteoric matter about one-tenth of a millimetre, of density say 2, over its whole surface in the course of the year. So far there is nothing impossible in the theory. But there are two fatal objections. The sun is a small target for a meteorite coming from infinity to hit, and if this considerable quantity reaches its mark, a much greater amount will circulate round the sun in parabolas, and there is no evidence of it where it would certainly make itself felt, in perturbations of the planets. A second objection is that it fails in its purpose, because 20,000,000 years ago it would give a sun quite as much changed as the contraction theory gave. If we examine chemical sources for maintenance of the sun's heat, combustion and other forms of combination are out of the question, because no combinations of different elements are known to exist at a temperature of 6000°. A source which seems plausible, perhaps only because it is less easy to test, is rearrangement of the structure of the elements' atoms. An atom is no longer figured as indivisible, it is made up of more or less complex, and more or less permanent, systems in internal circulation. Now under the law of attraction according to the inverse square of the distance, or any other inverse power beyond the first, the energy of even a single pair of material points is unlimited, if their possible closeness of approach to one another is unlimited. If the sources of energy within the atom can be drawn upon, and the phenomena of radio-activity leave no doubt about this, there is here an incalculable source of heat which takes the cogency out of any other calculation respecting the sources maintaining the sun's radiation. An equivalent statement of the same conclusion may be put thus: supposing a gaseous nebula is destined to condense into a sun, the elementary matter of which it is composed will develop in the process into our known terrestrial and solar elements, parting with energy as it does so.

Spectrum of the Sun. The continuous spectrum leads to no inference, except that of the temperature of the central globe; but the multitude of dark lines by which it is crossed reveal the elements composing the truly gaseous cloaks which enclose it. A table of these lines is a physical document as exact as it is intricate. The visual portion extends from about w.l.3700 to 7200 tenth-metres; the ultra-violet begins about 2970, beyond which point our atmosphere is almost perfectly opaque to it; the infra-red can be traced for more than ten times the visual length, but the gaps which indicate absorption-lines have not been mapped beyond 9870. The ultra-violet and the visual portion are recorded photographically; Rowland's classical work shows some 5700 lines in the former, and 14,200 in the latter, on a graduated scale of intensities from 1000 to 0, or 0000, for the faintest lines; between a quarter and a third of these lines have been identified, fully 2000 belonging to iron, and several hundred to water vapour and other atmospheric absorption. The infra-red requires special appliances; it has been examined visually by the help of phosphorescent plates (Becquerel), and with special photographic plates (Abney); but the most efficient way is to use the bolometer or radiomicrometer; by this means some 500 or 600 lines have been mapped.

The first problem of the spectrum is to identify the effects of atmospheric absorption, especially oxygen, carbonic acid and water vapour; this is done generally by comparing the spectra of the sun at great and small zenith-distances, or by reducing the atmospheric effect by observing from a great elevation, as did P. J. C. Janssen from the summit of Mont Blanc, but the only unquestionable test is to find those lines which are not touched by Doppler effect when the receding and advancing limbs of the sun are compared (Cornu); by this method H. F. Newall has verified the presence of cyanogen in the photosphere, and it had previously served to disprove the solar origin of certain oxygen lines. In fact, doubt long surrounded the presence of oxygen in the sun, and was not set at rest until K. D. T. Runge and F. Paschen in 1896 identified an unmistakable oxygen triplet in the infra-red, which is shown terrestrially only in the vacuum tube, where the spectrum is very different from that of atmospheric absorptions. The absence of lines of the spectrum of any element from the solar spectrum is no proof that the element is absent from the sun; apart from the possibility that the high temperature and other circumstances may show it transformed into some unknown mode, which is perhaps the explanation of the absence of nitrogen, chlorine and other non-metals; if the element is of high atomic weight we should expect it to be found only in the lowest strata of the sun's atmosphere, where its temperature was nearly equal to that of the central globe, and so any absorption line which it showed would be weak. This is undoubtedly the case with lead and silver, and probably with mercury also. In Rowland's table lines from the arc-spectra of the following are identified. The order is approximately that of the numbers of identified lines. Excepting strontium, those which are low upon the list are represented also by lines of small intensity. The chromosphere adds the three last of the list. The strongest lines are those due to calcium, iron, hydrogen, sodium, nickel, in the order named.

Iron	Neodymium	Aluminium	Bismuth (?)
Nickel	Lanthanum	Cadmium	Tellurium
Titanium	Yttrium	Rhodium	Indium
Manganese	Niobium	Erbium	Oxygen
Chromium	Molybdenum	Zinc	Tungsten
Cobalt	Palladium	Copper	Mercury (?)
Carbon	Magnesium	Silver	———
Vanadium	Sodium	Germanium	Helium
Zirconium	Silicon	Glucinum	Ytterbium
Cerium	Hydrogen	Tin	Europium
Calcium	Strontium	Lead	
Scandium	Barium	Potassium	

The spectrum taken near the limb of the sun shows increased general absorption, but also definite peculiarities of great interest in connexion with the spectra of the spots, which it will be convenient to describe first.

Sun-spot Spectrum.

When the slit of the spectroscope is set across a spot, it shows, as might be expected, a general reduction of brightness as we pass from the photosphere to the penumbra; and a still greater one as we pass to the umbra. This is not a uniform shade over the whole length of the spectrum, but shows in bands or flutings of greater or less darkness, which in places and at intervals have been resolved by Young, Dunér and other unquestionable observers into hosts of dark lines. Besides this the spectrum shows very many differences from the mean spectrum of the disk, the interpretation of which is at present far from clear. Generally speaking, the same absorption lines are present, but with altered intensities, which differ from one spot to another. Some lines of certain elements are always seen fainter or thinner than on the photosphere, or even wholly obliterated; others sometimes show the same features, but not always; other lines of the same elements, perhaps originating at a level above the spot, are not affected; there are also bright streaks where even the general absorption of the spot is absent, and sometimes such a bright line will correspond to a dark line on the photosphere; most generally the lines are intensified, generally in breadth, sometimes in darkness, sometimes in both together, sometimes in one at the expense of the other; certain lines not seen in the photosphere show only across the umbra, others cross umbra and penumbra, others reach a short distance over the photosphere. A few of the lines show a double reversal, the dark absorption line being greatly increased in breadth and showing a bright emission line in its centre. The umbra of a spot is generally not tormented by rapid line-of-sight motions; where any motion has been found G. E. Hale and W. S. Adams make its direction downwards; but round the rim and on bridges the characteristic distortions due to eruptive prominences are often observed. There appears to be some connexion between prominences and spots; quiescent prominences are sometimes found above the spots, and W. M. Mitchell records an eruptive prominence followed next day in the same place by the appearance of a small spot. It does not appear that the affected lines follow in any way the sun-spot cycle. The radiation from a spot changes little as it approaches the sun's limb; in fact Hale and Adams find that the absorption from the limb itself differs from that of the centre of the disk in a manner exactly resembling that from a spot, the same lines being strengthened or weakened in the same way, though in much less degree, with, however, one material exception: if a line is winged in the photosphere the wings are generally increased in the spot, but on the limb they are weakened or obliterated. If the spot spectrum is compared with that of the chromosphere it appears that the lines of most frequent occurrence in the latter are those least affected in the spot, and the high level chromospheric lines not at all; the natural interpretation is that the spot is below the chromosphere. As to whether the spots are regions of higher or lower temperature than the photosphere, the best qualified judges are reserved or discordant, but recent evidence seems to point very definitely to a lower temperature. Hale and Adams have shown that the spectrum contains, besides a strong line-spectrum of titanium, a faint banded spectrum which is that of titanium oxide, and a second banded part remarked by Newall has been identified by A. L. Fowler as manganese hydride. The band spectrum, which corresponds to the compound or at least to the molecule of titanium, certainly belongs to a lower temperature than the line spectrum of the same metal. Hence above the spots there are vapours of temperature low enough to give the banded spectra of this refractory metal, while only line spectra of sodium, iron and others fusible at more moderate temperatures are found (see also SPECTROHELIOGRAPH).

Chromosphere.

The chromosphere, which surrounds the photosphere, is a cloak of gases of an average depth of 5000 m., in a state of luminescence less intense than that of the photosphere. Hence when the photosphere is viewed through it an absorption spectrum is shown, but when it can be viewed separately a bright line spectrum appears. Most of the metallic vapours that produce this lie too close to the photosphere for the separation to be made except during eclipses, when a flash spectrum of bright lines shines out for, say, five seconds after the continuous spectrum has disappeared, and again before it reappears (see ECLIPSE). F. W. Dyson has measured some eight hundred lines in the lower chromosphere and identified them with emission spectra of the following elements: hydrogen, helium, carbon with the cyanogen band, sodium, magnesium, aluminium, silicon, calcium, scandium, titanium, vanadium, chromium, manganese, iron, zinc, strontium, yttrium, zirconium, barium, lanthanum, cerium, neodymium, ytterbium, lead, europium, besides a few doubtful identifications; it is a curious fact that the agreement is with the spark spectra of these elements, where the photosphere shows exclusively or more definitely the arc lines, which are generally attributed to a lower temperature. In the higher chromosphere the following were recognized: helium and parhelium, hydrogen, strontium, calcium, iron, chromium, magnesium, scandium and titanium.

In the higher chromosphere on occasions metallic gases are carried up to such a level that without an eclipse a bright line spectrum of many elements may be seen, but it is always possible to see those of hydrogen and helium, and by opening the slit of the spectroscope so as to weaken still further the continuous spectrum from the photosphere (now a mere reflection) the actual forms of the gaseous structures called prominences round the sun's rim may be seen. In the visual spectrum there are four hydrogen lines and one helium line in which the actual shapes may be examined. The features seen differ according to the line used, as the circumstances prevailing at different levels of the chromosphere call out one line or another with greater intensity. The helium formations do not reach the sun's limb, and it is another puzzling detail that the spectrum of the disk shows no absorption line of anything like an intensity to correspond with the emission line of helium in the chromosphere. The prominences are of two kinds, quiescent and eruptive. Some of the former are to be seen at the limb on most occasions; they may hang for days about the same place; they reach altitudes of which the average is perhaps 20,000 m., and show the spectral lines of hydrogen and helium. Sometimes they float above the surface, sometimes they are connected with it by stems or branches, and they show delicate striated detail like cirrus cloud. The eruptive prominences, called also metallic, because it is they which show at their bases a complete bright line spectrum of the metallic elements, rush upwards at speeds which it is difficult to associate with transfers of matter; the velocity *often* exceeds 100 m. a second; W. M. Mitchell watched one rise at 250 m. a second to the height of 70,000 m., and in five minutes after it had faded away and the region was quiet. This is remarkable only in point of velocity. Much greater heights occur. Young records one which reached an elevation of 350,000 m., or more than three-quarters of the sun's radius. Since identification of spectral lines is a matter of extreme refinement, any cause which may displace lines from their normal places, or otherwise change their features, must be examined scrupulously. We have seen above numerous applications of the Doppler effect. Two other causes of displacement call for mention in their bearing on the solar spectrum—pressure and anomalous dispersion. The pressure which produces a continuous spectrum in gases at a temperature of 6000° must be very great. Recent experiments on arc spectra at pressures up to 100 atmospheres by W. J. Humphreys and by W. C. Duffield show several suggestive peculiarities, though their bearing on solar phenomena is not yet determined. The lines are broadened (as was already known), the intensity of emission is much increased, but some are weakened and some strengthened, nor is the amount of broadening the same for all lines, nor is it always symmetrical, being sometimes greater on the red side; but besides the effect of unsymmetrical broadening, every line is displaced towards the red; different lines again behave differently, and they may be arranged somewhat roughly in a few groups according to their behaviour; reversals are also effected, and the reversed line does not always correspond with the most intense part of the emission line. For example, in the iron spectrum three groups about wave-length 4500 are found by Duffield to be displaced respectively 0·17, 0·34, 0·66 tenth-metres, at 100 atmospheres. This shift towards the red J. Larmor suggests is due to relaxation of the spring of the surrounding ether by reason of the crowding of the molecules; a shift of 0·17 tenth-metres would, if interpreted by Doppler's principle, have been read as a receding velocity of 11 km. per second. It is clear that these results may give a simple key to some puzzling anomalies, and on the other hand, they may throw a measure of uncertainty over absolute determinations of line-of-sight velocities.

Effect of Pressure on Spectral Lines.

Anomalous Dispersion.

The possible applications of anomalous dispersion are varied and interesting, and have recently had much attention given to them. W. H. Julius holds that this sole fact robs of objective reality almost all the features of the sun, including prominences, spots, faculae and flocculi, and even the eleven-year period. Though few follow him so far, an explanation of the principle will make it clear that there are numerous possible opportunities for anomalous dispersion to qualify inferences from the spectrum. Theoretically anomalous dispersion is inseparable from absorption. When a system vibrating in a free period of its own encounters, say through the medium of an enveloping aether, a second system having a different free period, and sets it in vibration, the amplitude of the second vibration is inconsiderable, except when the periods approach equality. In such a case the two systems must be regarded as a single more complex one, the absorbed vibration becomes large, though remaining always finite, and the transmitted vibration undergoes a remarkable change in its period. This is illustrated in fig. 13, where the effect of a single absorbing system upon vibrations of all wave-lengths is shown. The line η shows the factor by which the index of refraction of the transmitted vibration is multiplied, and the curve ρ the intensity of the absorbed vibration for that wave-length. The relative increase of index takes place on the side where the wave-length is greater than that of the absorbing system. The effect of such a change may be to bend back the coloured ribbon of the spectrum upon itself, but just where this is done all its light will be robbed to maintain the absorbing system in vibration. Theory is here much less intricate than fact, but it seems to cover the most important features and to be well confirmed. Omitting extreme examples, like fuchsin, where the spectrum is actually cut in two, it is of more general importance to detect the phenomenon in the ordinary absorption lines of the metallic elements. This has been done most completely by L. Puccianti, who measured it by the interferometer in the case of more than a hundred lines of different metals; he found its degree to differ much in different lines of the same spectrum.

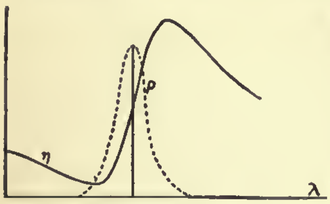

FIG. 13.

Differences of refractive index produce their greatest dispersive effects when incidence on the refracting surface is nearly tangential. W. H. Julius has used this fact in an admirable experiment to make the effects visible in the case of the D lines of sodium. A burner was constructed which gave a sheet of flame 750 mm. long and 1 mm. thick and to which sodium could be supplied in measured quantity. Light from an arc lamp was so directed that only that part reached the spectroscope which fell upon the flame of the burner at grazing incidence, and was thereby refracted. As the supply of sodium was increased, the lines, besides becoming broader, did so unsymmetrically, and a shaded wing or band appeared on one side or the other according as the beam impinged on one side or the other of the flame. These bands Julius calls dispersion bands, and then, assuming that a species of tubular structure prevails within a large part of the sun (such as the filaments of the corona suggest for that region), he applies the weakening of the light to explain, for instance, the broad dark H and K calcium lines, and the sun-spots, besides many remoter applications. But it should be noted that the bands of his experiment are not due to anomalous dispersion in a strict sense. They are formed now on one side, now on the other, of the absorption line; but the rapid increase of refractive index which accompanies true anomalous dispersion, and might be expected to produce similar bands by scattering the light, appears both from theory and experiment to belong to the side of greater wave-length exclusively. Julius's phenomenon seems inseparable from grazing incidence, and hence any explanation it supplies depends upon his hypothetical tubular structure for layers of equal density. There are other difficulties. In calcium, for instance, the g line shows in the laboratory much stronger anomalous dispersion than H and K; but in the solar spectrum H and K are broad out of all comparison to g. Hale has pointed out other respects in which the explanation fails to fit facts. In connexion with the question whether the phenomena of the sun are actually very different from what they superficially appear, A. Schmidt's theory of the photosphere deserves mention; it explains how the appearance of a sharp boundary might be due to a species of mirage.

Schmidt's Theory of the Photosphere.

Consider the rays which meet the eye (at unit distance) at an angle d from the centre of the sun's disk; in their previous passage through the partially translucent portions of this body we have the equation $\sin d = r\mu \sin i$ (fig. 14). Now generally μ will decrease as r increases, but the initial value of μ is not likely to be more than, say, twice its final value of unity, while r increases manifold in the same range, hence in general $r\mu$ will increase with r, and therefore for a given value of d, i will continually increase as we go inwards up to 90°, which it will attain for a certain value of r, and this will be the deepest

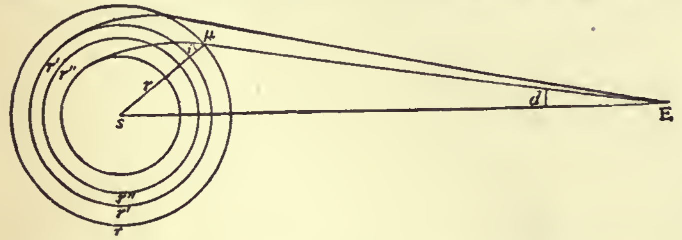

FIG. 14.

level of the sun's body from which rays will reach the eye at the given angle d. But if there is a region, say from r' to r'' throughout which $r\mu$ decreases as r increases, any ray which cuts the outer envelope r' at an acute angle will cut the inner one r'' also, and can be traced still further inwards before the angle i amounts to 90°. Apart then from absorption there will be a discontinuous change in brightness in the apparent disk at that value of the angular radius d which corresponds to tangential emission from the upper lever r' of this mirage-forming region. Of course we are unable to say whether such a region is an actuality in the sun, on the earth it is an exception and transient, but the greater the dimensions of the body the more probable is its occurrence. The theory can be put to a certain test by considering its implications with respect to colour. The greater μ is, the greater would be the value of d, the apparent angular radius, corresponding to horizontal emission from a given level r, and that whether we accept Schmidt's theory or not. Hence if the sun's diameter were measured through differently coloured screens, the violet disk must appear greater than the red. Now measures made by Auwers with the Cape heliometer showed no difference, amounting to 0·1″, and so far negative the idea that the rays reach us after issuing from a level where μ is sensibly different from unity. Presumably, then, the inner emissions are absorbed and those which reach us start from very near the surface.

The Sun's Distance.

The sun's distance is the indispensable link which connects terrestrial measures with all celestial ones, those of the moon alone excepted; hence the exceptional pains taken to determine it. The transits of Venus of 1874 and 1882 were observed by expeditions trained for the purpose beforehand with every possible foresight, and sent out by the British, French and German governments to occupy suitable stations distributed over the world, but they served only to demonstrate that no high degree of accuracy can ever be expected from this method. It is the atmosphere of Venus that spoils the observation. Whatever be the subsequent method of reduction, the instant is required when the planet's disk is in internal contact with that of the sun; but after contact has plainly passed it still remains connected with the sun's rim by a "black drop," with the result that trained observers using similar instruments set up a few feet from one another sometimes differed by half a minute of time in their record. It is little wonder, then, that the several reductions of the collected results were internally discordant so as to leave outstanding a considerable "probable error," but showed themselves able to yield very different conclusions when the same set was discussed by different persons. Thus from the British observations of 1874 Sir G. B. Airy deduced a parallax of 8·76″ and E. J. Stone 8·88″; from the French observations of the same date Stone deduced 8·88″ and V. Puiseux 8·91″. The first really adequate determinations of solar parallax were those of Sir David Gill, measured by inference from the apparent diurnal shift of Mars among the stars as the earth turned diurnally upon its axis; the observations were made at the island of Ascension in 1878. The disk of Mars and his colour are certain disadvantages, and Gill afterwards superseded his own work by treating in the same way the three minor planets Victoria, Iris and Sappho—the last was observed by W. L. Elkin. These planets are more remote than Mars, but that loss is more than outweighed by the fact that they are indistinguishable in appearance from stars. The measures were made with the Cape heliometer and have never been superseded, for the latest results with the minor planet Eros exactly confirm Gill's result—8·80″—while they decidedly diminish the associated probable error. The planet Eros was discovered in 1899, and proved to have an orbit between the earth and Mars, while every one of the other five or six hundred known asteroids lies between Mars and Jupiter. Its mean distance from the sun is 1·46 times that of the earth; but, besides, the eccentricity of its orbit is large (0·22), so that at the most favourable opportunity it can come within one-seventh of the distance of the sun. This favourable case is not realized at every opposition, but in 1900 the distance was as little as one-third of that of the sun, and it was observed from October 1900 to January 1901 photographically upon a concerted but not absolutely uniform plan by many observatories, of which the chief were the French national observatories, Greenwich, Cambridge, Washington and Mount Hamilton. The planet showed a stellar disk varying in magnitude from 9 to 12. On some plates the stars were allowed to trail and the planet was followed, in others the reverse procedure was taken; in either case the planet's position is measured by referring it to "comparison stars" of approximately its own magnitude situated within 25′ to 30′ of the centre of the plate, while these stars are themselves fixed by measurement from brighter "reference stars," the positions of which are found by meridian observations if absolute places are desired. The best results seem to be obtained by comparing an evening's observations with those of the following morning at the same observatory; the reference can then be made to the same stars and errors in their position are therefore virtually eliminated; even if the observations of a morning with those of the following evening are used the probable error is doubled. The observations at Greenwich thus reduced gave errors ±0·0036″ and ±0·0080″ respectively. The general result is 8·800″±0·0044″. To collate the whole of the material accumulated at different parts of the world is a much more difficult task; it requires first of all a most carefully constructed star-catalogue, upon which the further discussion may be built. The discussion was completed in 1909 by A. R. Hinks, and includes the material from some hundreds of plates taken at twelve observatories; in general it may be said the discussion proves that the material is distinctly heterogeneous, and that in places where it would hardly be expected. The result is nearly the same as found at Greenwich alone, 8·806″ ±0·0026″, or a mean distance of 92,830,000 m. $=1·493\times10^{13}$ cm. with an error which is as probably below as above 30,000 miles.

The sun's distance enters into other relations, three of which permit of its determination, viz. the equation of light, the constant of aberration, and the parallactic inequality of the moon; the value of the velocity of propagation of light enters in the reduction of the two first, but as this is better known than the sun's parallax, no disadvantage results. The equation of light is the time taken by light to traverse the sun's mean distance from the earth; it can be found by the acceleration or retardation of the eclipses of Jupiter's satellites according as Jupiter is approaching opposition or conjunction with the sun; a recent analysis shows that its value is 498·6″, which leads to the same value of the parallax as above, but the internal discrepancies of the material put its authority upon a much lower level. The constant of aberration introduces the sun's distance by a comparison between the velocity of the earth in its orbit and the velocity of light. Its determination is difficult, because it is involved with questions of the changing orientation of the earth's axis of rotation. S. C. Chandler considers the value 20·52″ is well established; this would give a parallax of 8·78″. The chief term in the lunar longitude which introduces the ratio of the distances of the sun and moon from the earth explicitly is known as the parallactic inequality; by analysis of the observations P. H. Cowell finds that its coefficient is 124·75″, which according to E. W. Brown's lunar theory would imply a parallax 8·778″.

The Sun's Dimensions. The best discussion of the sun's apparent diameter has been made by G. F. J. A. Auwers, in connexion with his reduction of the German observations of the transit of Venus of 1874 and 1882. It was found that personality played an important part; the average effect might be 1″, but frequently it reached 3″, 4″, 5″ or even 10″, with the same instrument and method, nor was it fixed for the same observer. Some 15,000 observations, from 1851 to 1883, taken by one hundred observers at Greenwich, Washington, Oxford and Neuchâtel, cleared as far as possible of personal equation, showed no sign of change that could with probability be called progressive or periodic, particularly there was no sign of adhesion to the sun-spot period. Better determinations of the actual value came from the heliometer, and gave an angular diameter of 31′ 59·26″±0·10″, and the value of the polar diameter exceeded the equatorial by 0·038″±0·023″. The conclusion is that the photosphere is very sharply defined and shows no definite departure from a truly spherical shape. Using the parallax 8·80″, the resulting diameter of the sun is 864,000 m. $=1·390\times10^{11}$ cm.

The Sun as a Star. If we regard the sun as one of the stars, the first four questions we should seek to answer are its distance from its neighbours, proper motion, magnitude and spectral type. In some respects the systematic prosecution of these inquiries has only begun, and properly considered they involve vast researches into the whole stellar system. It would take us too far to treat them at any length, but it may be convenient to summarize some of the results. The sun's nearest neighbour is α Centauri, which is separated from it by 270,000 times the earth's distance, a space which it would take light four years to traverse. It is fairly certain that not more than six stars lie within twice this distance. No certain guide has been found to tell which stars are nearest to us; both brightness and large proper motion, though of course increased by proximity, are apparently without systematic average relation to parallax.

The sun's proper motion among the stars has been sought in the past as the assumption that the universe of stars showed as a whole no definite displacement of its parts, and, on this assumption, different methods of reduction which attributed *apparent* relative displacement of parts to *real* relative displacement of the sun agreed fairly well in concluding that the "apex of the sun's way" was directed to a point in right ascension 275°, declination +37° (F. W. Dyson and W. G. Thackeray), that is to say, not far from the star Vega in the constellation Lyra, and was moving thither at a rate of twelve miles per second. But recent researches by J. C. Kapteyn and A. S. Eddington, confirmed by Dyson, show that there is better ground for believing that the universe is composed mainly of two streams of stars, the members of each stream actuated by proper motions of the same sense and magnitude on the average, than that the relative motions of the stars with one another are fortuitous (see Star). This removes completely the ground upon which the direction of the sun's way has hitherto been calculated, and leaves the question wholly without answer.

A star is said to rise one unit in magnitude when the logarithm of its brightness diminishes by 0·4. Taking as a star of magnitude 1 α Tauri or α Aquilae, where would the sun stand in this scale? Several estimates have been made which agree well together; whether direct use is made of known parallaxes, or comparison is made with binaries of well-determined orbits of the same spectral type as the sun, in which therefore it may be assumed there is the same relation between mass and brilliancy (Gore), the result is found that the sun's magnitude is −26·5, or the sun is 10^{11} times as brilliant as a first magnitude star; it would follow that the sun viewed from α Centauri would appear as of magnitude 0·7, and from a star of average distance which has a parallax certainly less than 0·1″, it would be at least fainter than the fifth magnitude, or, say, upon the border-line for naked-eye visibility. We cannot here do more than refer to the spectral type of the sun. It is virtually identical with a group known as the "yellow stars," of which the most prominent examples are Capella, Pollux and Arcturus; this is not the most numerous group, however; more than one half of all the stars whose spectra are known belong to a simpler type in which the metallic lines are faint or absent, excepting hydrogen and sometimes helium, which declare themselves with increased prominence. These are the white stars, and the most prominent examples are Sirius, Vega and Procyon. It is commonly though not universally held that the difference between the white and yellow stars arises from their stages of development merely, and that the former represent the earlier stage. This again is disputed, and there is indeed as yet slight material for a decisive statement.

Summary of Numerical Data.

Parallax: 8·806″ ± 0·003″.
Mean distance from earth: 92,830,000 m. $=1·493\times10^{13}$ cm.
(Time taken by light to traverse this distance: 498·6″).
Diameter: Angular, at mean distance, 1919·3″.
Linear, 109×earth's equatorial diameter=864,000 m.= $1·390\times10^{11}$ cm.
Mass: 332,000×mass of the earth.
Mean density: ·256×mean density of earth=1·415.
Equator; inclination to ecliptic: 7° 15′.
Longitude of ascending node (1908·0), 74° 28·6′.
Rotation period; latitude 0°: 24·46^d
30°: 26·43^d
60°: 29·63^d
80°: 30·56^d
Solar constant, or units of energy received per minute per square centimetre at earth's mean distance: 2·1 calories.
Effective temperature, as an ideal radiator or "black body": 6000° abs.

Bibliography.—Nearly all the chief data respecting the sun have lately been and still are under active revision, so that publications have tended to fall rapidly out of date. The most important series is the *Astrophysical Journal*, which is indispensable, and in itself almost sufficient; among other matter it contains all the publications of Mount Wilson Solar Observatory (Professor G. E. Hale), H. A. Rowland's *Tables of Wave-Lengths*, many theoretical papers, and some reproductions of important papers issued elsewhere. But there are also papers which cannot be disregarded in *Monthly Notices* and *Memoirs of the Royal Astronomical Society*, and in *Astronomische Nachrichten*. S. P. Langley's *Researches on Solar Heat* are published by the War Department (Signal Service, xv.) (Washington, 1884), and Gill's parallax researches in *Cape Annals*, vols. vi., vii. Auwer's discussion of the sun's diameter is in the discussion of the transit of Venus observations for 1874 and 1882. The best single volume upon the whole subject is C. A. Young's *The Sun*, 2nd ed. (Inter. Sci. Series), and an excellent summary of solar spectroscopy, as far as rapid progress permits, is in Frost's translation of Scheiner, *Astronomical Spectroscopy* (1894). Scheiner's volume, *Strahlung u. Temperatur d. Sonne* (1899), contains a great quantity of interesting matter carefully collected and discussed. For authoritative declarations upon the latest moot points the *Transactions of the International Union for Solar Research* (Manchester) may be consulted, vol. i. having been issued in 1906, and vol. ii. in 1908. (R. A. Sa.)

SUN-BIRD, a name more or less in use for many years,[1] and now generally accepted as that of a group of over 100 species of small birds, but when or by whom it was first applied is uncertain. Those known to the older naturalists were for a long while referred to the genus *Certhia* (Tree-creeper, *q.v.*) or some other group, but they are now fully recognized as forming a valid Passerine family Nectariniidae, from the name *Nectarinia* invented in 1881 by Illiger. They inhabit the Ethiopian, Indian, and Australian regions,[2] and, with some notable exceptions, the species mostly have but a limited range. They are considered to have their nearest allies in the Meliphagidae (see Honey-eater) and the members of the genus *Zosterops*;

[1] Certainly since 1826 (cf. Stephens, *Gen. Zoology*, vol. xiv. pt. 1, p. 292). W. Swainson (*Nat. Hist. and Classif. Birds*, i. 145) says they are "so called by the natives of Asia in allusion to their splendid and shining plumage," but gives no hint as to the nation or language wherein the name originated. By the French they have been much longer known as "Souimangas," from the Madagascar name of one of the species given in 1658 by Flacourt as *Soumangha*.

[2] One species occurs in Baluchistan, which is perhaps outside of the Indian region, but the fact of its being found there may be a reason for including that country within the region, just as the presence of another species in the Jordan valley induces zoographers to regard the Ghór as an outlier of the Ethiopian region.

but their relations to the last require further investigation. Some of them are called "humming-birds" by Anglo-Indians and colonists, but with that group, which, as before indicated (see HUMMING-BIRD), belongs to the *Picariae*, the sun-birds, being true *Passeres*, have nothing to do. Though part of the plumage in many sun-birds gleams with metallic lustre, they owe much of their beauty to feathers which are not lustrous, though almost as vivid,[1] and the most wonderful combination of the brightest colours—scarlet, purple, blue, green and yellow —is often seen in one and the same bird. One group, however, is dull in hue, and but for the presence in some of its members of yellow or flame-coloured precostal tufts, which are very characteristic of the family, might at first sight be thought not to belong here. Graceful in form and active in motion, sun-birds flit from flower to flower, feeding on small insects which are attracted by the nectar and on the nectar itself; but this is usually done while perched and rarely on the wing as is the habit of humming-birds. The extensible tongue, though practically serving the same end in both groups, is essentially different in its quasi-tubular structure, and there is also considerable difference between this organ in the Nectariniidae and the Meliphagidae.[2] The nests of the sun-birds, domed with a penthouse porch, and pensile from the end of a bough or leaf, are very neatly built. The eggs are generally three in number, of a dull white covered with confluent specks of greenish grey.

The Nectariniidae form the subject of a sumptuous *Monograph* by G. E. Shelley (4to, London, 1876–1880), in the coloured plates of which full justice is done to the varied beauties which these gloriously arrayed little beings display, while almost every available source of information has been consulted and the results embodied. This author divides the family into three sub-families: Neodrepaninae, consisting of a single genus and species peculiar to Madagascar; Nectariniinae, containing 9 genera, one of which, *Cinnyris*, has more than half the number of species in the whole group; and Arachnotherinae (sometimes known as "spider-hunters"), with 2 genera including 11 species—all large in size and plain in hue. To these he also adds the genus *Promerops*,[3] composed of 2 species of South African birds, of very different appearance, whose affinity to the rest can as yet hardly be taken as proved. According to E. L. Layard, the habits of the Cape *Promerops*, its mode of nidification, and the character of its eggs are very unlike those of the ordinary Nectariniidae. In the British Museum *Catalogue of Birds* (ix. 1–126 and 291) H. J. Gadow has more recently treated of this family, reducing the number of both genera and species, though adding a new genus discovered since the publication of Shelley's work.

(A. N.)

SUN-BITTERN, the *Eurypyga helias* of ornithology, a bird that has long exercised systematists and one whose proper place can scarcely yet be said to have been determined to everybody's satisfaction.

According to Pallas, who in 1781 gave (*N. nördl. Beyträge*, vol. ii. pp. 48–54, pl. 3) a good description and fair figure of it, calling it the "Surinamische Sonnenreyger," *Ardea helias*, the first author to notice this form was Fermin, whose account of it, under the name of "Sonnenvogel," was published at Amsterdam in 1759 (*Descr., &c., de Surinam*, ii. 192), but was vague and meagre. In 1772, however, it was satisfactorily figured and described in Rozier's *Observations sur la physique*, &c. (vol. v. pt. 1, p. 212, pl. 1), as the *Petit paon des roseaux*—by which name it was known in French Guiana.[4] A few years later D'Aubenton figured it in his well-known series (*Pl. Enl.*, p. 782), and then in 1781 came Buffon (*H.N.*, *Oiseaux*, vol. viii. pp. 169, 170, pl. xiv.), who, calling it "Le Caurlâ ou petit paon des roses," announced it as hitherto undescribed and placed it among the Rails. In the same year appeared the above-cited paper by Pallas, who, notwithstanding his remote abode, was better informed as to its history than his great contemporary, whose ignorance, real or affected, of his fellow-countryman's priority in the field is inexplicable; and it must have been by inadvertence that, writing "roses" for "roseaux," Buffon turned the colonial name from one that had a good meaning into nonsense. In 1783 Boddaert, equally ignorant of what Pallas had done, called it *Scolopax solaris*,[5] and in referring it to that genus he was followed by Latham (*Synopsis*, iii. 156), by whom it was introduced to English readers as the "Caurale Snipe." Thus within a dozen years this bird was referred to three perfectly distinct genera, and in those days genera meant much more than

(From *Cambridge Natural History*, vol. ix., "Birds," by permission of Macmillan & Co., Ltd.)

FIG. 1.—Sun-Bittern (*Eurypyga helias*).

they do now. Not until 1811 was it recognized as forming a genus of its own. This was done by Illiger, whose appellation, *Eurypyga* has been generally accepted.

The sun-bittern is about as big as a small curlew, but with much shorter legs and a rather slender, straight bill. The wings are moderate, broad, and rounded, the tail rather long and broad. The head is black with a white stripe over and another under each eye, the chin and throat being also white. The rest of the plumage is not to be described in a limited space otherwise than generally, being variegated with black, brown, chestnut, bay, buff, grey and white—so mottled, speckled and belted either in wave-like or zigzag forms as somewhat to resemble certain moths. The bay colour forms two conspicuous patches on each wing, and also an antepenultimate bar on the tail, behind which is a subterminal band of black. The irides are red; the bill is greenish olive; and the legs are pale yellow. As in the case of most South American birds, very little is recorded of its habits in freedom, except that it frequents the muddy and wooded banks of rivers, feeding on small fishes and insects. In captivity it soon becomes tame, and has several times made its nest and reared its young (which, when hatched, are clothed with mottled down; *Proc. Zool. Soc.*, 1866, p. 76, pl. ix. fig. 1) in the Zoological Gardens (London), where examples are generally to be seen and their plaintive piping heard. It ordinarily walks with slow and precise steps, keeping its body in a horizontal position, but at times, when excited, it will go through a series of fantastic performances, spreading its broad wings and tail so as to display their beautiful markings. This species inhabits Guiana and the interior of Brazil; but in Colombia and Central America occurs a larger and somewhat differently coloured form which is known as *E. major*.

For a long while it seemed as if *Eurypyga* had no near ally, but on the colonization of New Caledonia by the French, an extremely curious bird was found inhabiting most parts of that island, to which it is peculiar. This the natives called the Kagu, and it is the *Rhinochetus jubatus* of ornithology. Its original describers, MM. Jules Verreaux and Des Murs, regarded it first as a heron and then as a crane (*Rev. et Mag. de Zoologie*, 1860, pp. 439–441, pl. 21; 1862, pp. 142–144); but, on Mr George Bennett sending two live examples to the Zoological Gardens, Mr Bartlett quickly detected in them an affinity to *Eurypyga* (*Proc. Zool. Soc.*, 1862, pp. 218, 219, pl. xxx.), and in due time anatomical investigation showed him to be right. The kagu, however, would not strike the ordinary observer as having much outward resemblance to the sun-bittern, of which it has neither the figure nor posture. It is rather a long-legged bird, about as large as an ordinary fowl, walking quickly

[1] Cf. H. J. Gadow, *Proc. Zool. Soc.* (1882), pp. 409–421, pls. xxvii., xxviii.

[2] Ibid. (1883), pp. 62–69, pl. xvi.

[3] According to M. J. Brisson (*Ornithologie*, ii. 460), this name was the invention of Réaumur. It seems to have become Anglicized.

[4] This figure and description were repeated in the later issue of this work in 1777 (vol. i. pp. 679–781, pl. 1).

[5] Possibly he saw in the bird's variegated plumage a resemblance to the painted snipes, *Rhynchaea*. His specific name shows that he must have known how the Dutch in Surinam called it.

and then standing almost motionless, with bright red bill and legs, large eyes, a full pendent crest, and is generally of a light slate-colour, paler beneath, and obscurely barred on its longer wing-coverts and tail with a darker shade. It is only when it spreads its wings that these are seen to be marked and spotted with white, rust-colour, and

FIG. 2.—Kagu (*Rhinochetus jubatus*).

black, somewhat after the pattern of those of the sun-bittern. Like that bird, too, the kagu will, in moments of excitement, give up its ordinary placid behaviour and execute a variety of violent gesticulations, some of them even of a more extraordinary kind, for it will dance round, holding the tip of its tail or one of its wings in a way that no other bird is known to do. Its habits in its own country were described at some length in 1863 by M. Jouan (*Mém. Soc. Sc. Nat. Cherbourg*, ix. 97 and 235), and in 1870 by M. Marie (*Actes Soc. Linn. Bordeaux*, xxvii. 323–326), the last of whom predicts the speedy extinction of this interesting form, a fate foreboded also by the statement of Messrs Layard (*Ibis*, 1882, pp. 534, 535) that it has nearly disappeared from the neighbourhood of the more settled and inhabited parts.

The internal and external structure of both these remarkable forms is now fully known and it appears that they, though separable as distinct families, Eurypygidae and Rhinochetidae, must be deemed the relics of very ancient and generalized types more or less related to the Rallidae (see RAIL), and Psophiidae (see TRUMPETER). It is only to be remarked that the eggs of both *Eurypyga* and *Rhinochetus* have a very strong ralline appearance—stronger even than the figures published (*Proc. Zool. Soc.*, 1868, pl. 12) would indicate. (A. N.)

SUNBURY, a borough and the county seat of Northumberland county, Pennsylvania, U.S.A., on the Susquehanna river about 53 m. by rail N. by E. of Harrisburg. Pop. (1900), 9810, of whom 197 were foreign-born; (1910 U.S. census) 13,770. It is served by the Pennsylvania, the Northern Central (controlled by the Pennsylvania) and the Philadelphia & Reading railways. Sunbury's principal industry is the manufacture of silk; the Pennsylvania railway has repair shops here. The total value of the borough's factory products increased from $1,868,157 in 1900 to $2,592,829 in 1905, or 38·8%. The borough stands on the site of the old Indian village, Shamokin, which was occupied by Delawares, Senecas and Tutelos, and was long the most prominent Indian village in the province; in 1747–1755 there was a Moravian mission here. Owing to the strategic importance of the place the provincial government erected Fort Augusta here in 1756; during the War of Independence many of the fugitives from the Wyoming Massacre came to this fort. Sunbury was first surveyed in 1772 and was incorporated as a borough in 1797.

SUNBURY-ON-THAMES, an urban district in the Uxbridge parliamentary division of Middlesex, England, 17 m. S.W. of St Paul's Cathedral, London, on a branch of the London & South Western railway. Pop. (1901), 4544. It is a favourite riverside resort and has grown considerably as a residential district. The church of St Mary, Byzantine in style, dates from 1752. There are pumping works and filtration beds for the water-supply of London. To the north-east is Kempton Park, the manor-house of which was a royal residence early in the 14th century. The park is famous for its race-meetings, the principal fixture being the Jubilee Handicap, established in 1887. The manor was granted by Edward the Confessor to Westminster Abbey, and passed in the 13th century to the see of London and in the 16th to the Crown; but was not so held later than 1603.

SUN COPYING, or PHOTO COPYING, the name given to that branch of photographic contact printing which is carried out without the aid of a camera-made negative. It is now used very extensively for copying documents, especially the plans of architects and engineers.

The earliest discovered process, the ferroprussiate, is still the one most largely used, on account of its economy and permanence, combined with a simplicity of manipulation that renders it highly suitable for office use; it was invented in 1840 by Sir John Herschel. This method has the disadvantage that the copies are blue in colour, and, as it is a negative process, the black lines of the original become the white lines of the print; the development is by washing in water, so that the important feature of accuracy of scale is lost. The next step of importance was in 1864, when William Willis of Birmingham, the father of the inventor of the platinotype system of photographic printing, invented the aniline process. In this method a paper sensitized with bichromate of potassium is exposed to light, with the document (generally a tracing) in front of it; the unprotected lines are bleached out, but the protected ones remain and are developed by contact with vapour of aniline, a subsequent washing for the removal of chemicals completing the print. For twenty years this process was successfully used with little opposition other than that of the blue prints previously referred to, and of the Pellet process, which gave a blue line on a white ground, the inventor being associated throughout with the firm of Vincent Brooks, Day & Son; but since that time a large number of other methods have come into use, some requiring a paper negative in the first instance and some not, but all much aided by improved methods of applying electric light. The earliest of these improved systems utilizing electric light was that invented by Mr B. J. Hall, whose photo-copier consists of two semi-circular glasses forming a cylinder, which may be revolved, and through which an arc lamp travels, while the tracing and sensitized paper are strapped to its outer surface.

Between 1900 and 1908 attention was chiefly directed to overcoming the variation of scale that is inevitable in all systems that require a final washing in water either for development or for the removal of chemicals; and at least four excellent systems have arisen. While Mr F. R. Vandyke was perfecting the system which he patented in 1901 and which has been adopted by the Ordnance Survey Department at Southampton, Messrs Vincent Brooks, Day & Son were working along somewhat similar lines, the outcome of which was their "True-to-Scale Photo Litho" system. In both these methods a reversed positive print is secured on zinc, from which copies can be made in printer's ink of any colour by the usual lithographic method on almost any material that may be desired. The plates prepared by these methods are so sensitive to light that excellent results can be secured from drawings made even on semi-transparent material such as drawing paper, and of course the plates when made are capable of alteration or addition and can be stored for reprints.

An admirable process had since been invented by MM. Dorel Frères of Paris, which is even more expeditious, and being less in prime cost is more suitable when only a small number of prints is required. In this case a large sheet of thin zinc is coated with chemically-treated gelatin, with the result that when a ferroprussiate print is pressed down on it either with the hand or by a roller the protected lines affect the gelatin in such a way that the parts that have been in contact with them receive a greasy ink while the remainder of the surface rejects it, so that a small number (not generally exceeding six) of very excellent prints can be secured. The inventors refrained from taking out a patent either in France or elsewhere, preferring to work their invention as a secret process, but the formula appears either to have leaked out or to have been discovered, so that the process is, perhaps with slight variations, used under numerous names. With the aid of the various systems of rotary copiers, by which blue prints of almost any length can be secured, Dorel prints identical in scale with the originals have been made of the length of 22 feet. An interesting kindred process but with well defined variations is known as velography.

For the technical and chemical details of the various methods reference may be made to *Ferric and Heliographic Processes* by G. E. Brown (Dawbarn & Ward). (F. V. B.)

SUNDA ISLANDS, the collective name of the islands in the Malay Archipelago which extend from the Malay Peninsula to the Moluccas. They are divided into the Great Sunda Islands—*i.e.* Sumatra, Java, Borneo, Celebes, Banka and Billiton, with their adjacent islands—and the Little Sunda Islands, of which the more important are Bali, Lombok, Sumbawa, Flores, Sumba and Timor.

Sunda Strait is the channel separating Sumatra from Java and uniting the Indian Ocean with the Java Sea. It is 15 m. broad between the south-eastern extremity of Sumatra and the town of Anjer in Java. In the middle is the low-lying well-wooded island of Dwars-in-den-Weg ("right in the way"), otherwise Middle Island or Sungian. In 1883 Sunda Strait was the scene of the most terrific results of the eruption of Krakatoa (*q.v.*), a volcanic island further west in the strait.

SUNDARBANS, or Sunderbunds, a tract of waste country in Bengal, India, forming the seaward fringe of the Gangetic delta. It has never been surveyed, nor has the census been extended to it. It stretches for about 165 m., from the mouth of the Hugli to the mouth of the Meghna, and is bordered inland by the three settled districts of the Twenty-four Parganas, Khulna and Backergunje. The total area (including water) is estimated at 6526 sq. m. It is a water-logged jungle, in which tigers and other wild beasts abound. Attempts at reclamation have not been very successful. The forest department realizes a large revenue, chiefly by tolls on produce removed. The characteristic tree is the *sundri* (*Heritiera littoralis*), from which the name of the tract has probably been derived. It yields a hard wood, used for building, and for making boats, furniture, &c. The Sundarbans are everywhere intersected by river channels and creeks, some of which afford water communication between Calcutta and the Brahmaputra valley, both for steamers and for native boats.

SUNDAY, or the Lord's Day (ἡ τοῦ ἡλίου ἡμέρα, *dies solis*; ἡ κυριακὴ ἡμέρα, *dies dominica*, *dies dominicus*[1]), in the Christian world, the first day of the week, celebrated in memory of the resurrection of Christ, as the principal day for public worship. An additional reason for the sanctity of the day may have been found in its association with Pentecost or Whitsun.[2] There is no evidence that in the earliest years of Christianity there was any formal observance of Sunday as a day of rest or any general cessation of work. But it seems to have from the first been set apart for worship. Thus according to Acts xx. 7, the disciples in Troas met weekly on the first day of the week for exhortation and the breaking of bread; 1 Cor. xvi. 2 implies at least some observance of the day; and the solemn commemorative character it had very early acquired is strikingly indicated by an incidental expression of the writer of the Apocalypse (i. 10), who for the first time gives it that name ("the Lord's Day") by which it is almost invariably referred to by all writers of the century immediately succeeding apostolic times.[3] Indications of the manner of its observance during this period are not wanting. *Teaching of the Apostles* (c. 14) contains the precept: "And on the Lord's day of the Lord (κατὰ κυριακὴν κυρίου) come together and break bread and give thanks after confessing your transgressions, that your sacrifice may be pure." Ignatius (*Ad Magn.* c. 9) speaks of those whom he addresses as "no longer Sabbatizing, but living in the observance of the Lord's day (κατὰ κυριακὴν ζῶντες) on which also our life sprang up again."[4] Eusebius (*H.E.* iv. 23) has preserved a letter of Dionysius of Corinth (A.D. 175) to Soter, bishop of Rome, in which he says: "To-day we have passed the Lord's holy day, in which we have read your epistle"; and the same historian (*H.E.* iv. 26) mentions that Melito of Sardis (A.D. 170) had written a treatise on the Lord's day. Pliny's letter to Trajan in which he speaks of the meetings of the Christians "on a stated day" need only be alluded to. The first writer who mentions the name of Sunday as applicable to the Lord's day is Justin Martyr; this designation of the first day of the week, which is of heathen origin (see Sabbath), had come into general use in the Roman world shortly before Justin wrote. He describes (*Apol.* i. 67) how "on the day called Sunday" town and country Christians alike gathered together in one place for instruction and prayer and charitable offerings and the distribution of bread and wine; they thus meet together on that day, he says, because it is the first day in which God made the world, and because Jesus Christ on the same day rose from the dead.

As long as the Jewish Christian element continued to have any influence in the Church, a tendency to observe Sabbath as well as Sunday naturally persisted. Eusebius (*H.E.* iii. 27) mentions that the Ebionites continued to keep both days, and there is abundant evidence from Tertullian onwards that so far as public worship and abstention from fasting are concerned the practice was widely spread among the Gentile churches. Thus we learn from Socrates (*H.E.* vi. c. 8) that in his time public worship was held in the churches of Constantinople on both days; the *Apostolic Canons* (can. 66 [65]) sternly prohibit fasting on Sunday or Saturday (except Holy Saturday); and the injunction of the *Apostolic Constitutions* (v. 20; cf. ii. 59, vii. 23) is to "hold your solemn assemblies and rejoice every Sabbath day (excepting one), and every Lord's day." Thus the earliest observance of the day was confined to congregational worship, either in the early morning or late evening. The social condition of the early Christians naturally forbade any general suspension of work. Irenaeus (*c.* 140–202) is the first of the early fathers to refer to a tendency to make Sunday a day of rest in his mention that harvesting was forbidden by the Church on the day. Tertullian, writing in 202, says "On the Lord's day we ought abstain from all habit and labour of anxiety, putting off even our business." But the whole matter was placed on a new footing when the civil power, by the constitution of Constantine mentioned below, began to legislate as to the Sunday rest. The fourth commandment, holding as it does a conspicuous place in the decalogue, the precepts of which could not for the most part be regarded as of merely transitory obligation, and never of course escaped the attention of the fathers of the Church; but, remembering the liberty given in the Pauline writings "in respect of a feast day or a new moon or a Sabbath" (Col. ii. 16; cf. Rom. xiv. 5, Gal. iv. 10, 11), they usually explained the "Sabbath day" of the commandment as meaning the new era that had been introduced by the advent of Christ, and interpreted the rest enjoined as meaning cessation from sin. But when a series of imperial decrees had enjoined with increasing stringency an abstinence from labour on Sunday, it was inevitable that the Christian conscience should be roused on the subject of the Sabbath rest also, and in many minds the tendency would be such as finds expression in the *Apostolic Constitutions* (viii. 33): "Let the slaves work five days; but on the Sabbath day and the Lord's day let them have

[1] The Teutonic and Scandinavian nations adopt the former designation (Sunday, *Sonntag*, *Söndag*, &c.), the Latin nations the latter (*dimanche*, *domenica*, *domingo*, &c.).

[2] From an expression in the Epistle of Barnabas (c. 15), it would almost seem as if the Ascension also was believed by some to have taken place on a Sunday.

[3] In the Epistle of Barnabas already referred to (c. 15) it is called "the eighth day": "We keep the eighth day with joyfulness, the day also in which Jesus rose again from the dead." Cf. Justin Martyr, *Dial. c. Tryph.* c. 138.

[4] The longer recension runs: "But let every one of you keep the Sabbath after a spiritual manner . . . And after the observance of the Sabbath let every friend of Christ keep the Lord's day as a festival, the resurrection day, the queen and chief of all the days." The writer finds a reference to the Lord's day in the titles to Ps. vi. and xii., which are "set to the eighth."

leisure to go to church for instruction in piety." There is evidence of the same tendency in the opposite canon (29) of the council of Laodicea (363), which forbids Christians from Judaizing and resting on the Sabbath day, and actually enjoins them to work on that day, preferring the Lord's day and so far as possible resting as Christians. About this time accordingly we find traces of a disposition in Christian thinkers to distinguish between a temporary and a permanent element in the Sabbath day precept; thus Chrysostom (10th homily on Genesis) discerns the fundamental principle of that precept to be that we should dedicate one whole day in the circle of the week and set it apart for exercise in spiritual things. The view that the Christian Lord's day or Sunday is but the Christian Sabbath transferred from the seventh to the first day of the week does not find categorical expression till a much later period, Alcuin being apparently the first to allege of the Jewish Sabbath that "ejus observationem mos Christianus ad diem dominicam competentius transtulit" (cf. DECALOGUE).

LAW RELATING TO SUNDAY

The earliest recognition of the observance of Sunday as a legal duty is a constitution of Constantine in 321 A.D., enacting that all courts of justice, inhabitants of towns, and workshops were to be at rest on Sunday (*venerabili die solis*), with an exception in favour of those engaged in agricultural labour. This was the first of a long series of imperial constitutions, most of which are incorporated in the Code of Justinian, bk. iii. tit. 12 (*De feriis*). The constitutions comprised in this title of the code begin with that of Constantine, and further provide that emancipation and manumission were the only legal proceedings permissible on the Lord's day (*die dominico*), though contracts and compromises might be made between the parties where no intervention of the court was necessary. Pleasure was forbidden as well as business. No spectacle was to be exhibited in a theatre or circus. If the emperor's birthday fell on a Sunday, its celebration was to be postponed. The seven days before and after Easter were to be kept as Sundays. In Cod. i. 4, 9, appears the regulation that prisoners were to be brought up for examination and interrogation on Sunday. On the other hand, Cod. iii. 12, 10, distinctly directs the torture of robbers and pirates, even on Easter Sunday, the divine pardon (says the law) being hoped for where the safety of society was thus assured. After the time of Justinian the observance of Sunday appears to have become stricter. In the West, Charlemagne forbade labour of any kind. A century later in the Eastern Empire No. liv. of the Leonine constitutions abolished the exemption of agricultural labour contained in the constitution of Constantine; but this exemption was specially preserved in England by a constitution of Archbishop Meopham. The canon law followed the lines of Roman law. The decrees of ecclesiastical councils on the subject have been numerous. Much of the law is contained in the Decretals of Gregory, bk. ii. tit. 9 (*De feriis*), c. 1 of which (translated) runs thus: "We decree that all Sundays be observed from vespers to vespers (*a vespera ad vesperam*), and that all unlawful work be abstained from, so that in them trading or legal proceedings be not carried on, or any one condemned to death or punishment, or any oaths be administered, except for peace or other necessary reason." Works of necessity (especially in the case of perishable materials or where time was important, as in fishing) were allowed, on condition that a due proportion of the gain made by work so done was given to the church and the poor. The consent of parties was insufficient to give jurisdiction to a court of law to proceed on Sunday, though it was sufficient in the case of a day sanctified by the ecclesiastical authority for a temporary purpose, *e.g.* a thanksgiving for vintage or harvest.

In England legislation on the subject began early and continues down to the most modern times. As early as the 7th century the laws of Ina, king of the West Saxons, provided that, if a "theowman" worked on Sunday by his lord's command, he was to be free and the lord to be fined 30s.; if a freeman worked without his lord's command, the penalty was forfeiture of freedom or a fine of 60s., and twice as much in the case of a priest. The laws of Æthelstan forbade marketing, of Æthelred folkmoots and hunting, on the Sunday. In almost all the pre-Conquest compilations there are admonitions to keep the day holy. The first allusion to Sunday in statute law proper is in 1354 (28 Edw. III. c. 14 rep.), forbidding the sale of wool at the staple on Sunday. The mass of legislation from that date downwards may be conveniently, if not scientifically, divided into five classes—ecclesiastical, constitutional, judicial, social and commercial. The terms "Sunday" and "Lord's day" are used in the statutes, but the term "Sabbath" occurs only in ordinances of the Long Parliament. "Sabbath-breaking" is sometimes used to describe a violation of the Sunday observance acts, but is objected to by Blackstone as legally incorrect. Good Friday and Christmas Day are as a rule in the same legal position as Sunday. In English law Sunday is reckoned from midnight to midnight, not as in canon law *a vespera ad vesperam*.

The acts to be mentioned are still law unless the contrary is stated.

Ecclesiastical.—Before the Reformation there appears to be little or no statutory recognition of Sunday, except as a day on which trade was interdicted or national sports directed to be held. Thus the repealed acts of 1388 (12 Ric. II. c. 6) and 1409 (11 Hen. IV. c. 4) enjoined the practice of archery on Sunday. The church itself by provincial constitutions and other means declared the sanctity of the day, and was strong enough to visit with its own censures those who failed to observe Sunday. At the Reformation it was thought necessary to enforce the observance of Sunday by the state in face of the question mooted at the time as to the divine or merely human institution of the day as a holy day. Sunday observance was directed by injunctions as well as by statutes of Edward VI. and Elizabeth. The second Act of Uniformity of 1551 (5 & 6 Edw. IV. c. 1.) enacted that all inhabitants of the realm were to endeavour themselves to resort to their parish church or chapel accustomed, or upon reasonable let thereof to some usual place where common prayer is used every Sunday, upon pain of punishment by the censures of the church. The same principle was re-enacted by the Act of Uniformity of 1558 (1 Eliz. c. 2), with the addition of a temporal punishment, viz. a fine of twelve pence for each offence. This section of the act is, however, no longer law, and it appears that the only penalty now incurred by non-attendance at church is the shadowy one of ecclesiastical censure. Protestant dissenters, Jews and Roman Catholics were in 1846 (9 & 10, Vict. c. 59) exempted from the act, and the pecuniary penalties were abrogated as to all persons; but the acts as to Sundays and holy days are still binding on members of the Church of England [*Marshall* v. *Graham*, 1907, 2 K.B. 112].

An act of 1551 (5 & 6 Edw. VI. c. 3) directed the keeping of all Sundays as holy days, with an exception in favour of husbandmen, labourers, fishermen and other persons in harvest or other time of necessity. Canon 13 of the canons of 1603 provides that "all manner of persons within the Church of England shall celebrate and keep the Lord's day, commonly called Sunday, according to God's holy will and pleasure and the orders of the Church of England prescribed in that behalf, that is, in hearing the word of God read and taught, in private and public prayers, in acknowledging their offences to God and amendment of the same, in reconciling themselves charitably to their neighbours where displeasure hath been, in oftentimes receiving the communion of the body and blood of Christ, in visiting the poor and sick, using all godly and sober conversation." The Long Parliament, by an ordinance of 1644, c. 51, directed the Lord's day to be celebrated as holy, as being the Christian Sabbath. Ordinances of 1650, c. 9, and 1656, c. 15, contained various minute descriptions of crimes against the sanctity of the Lord's day, including travelling and "vainly and profanely walking." These ordinances lapsed at the Restoration. The Act of Uniformity of 1661 (13 & 14 Car. II. c. 4) enforced the reading on every Lord's day of the morning and evening prayer according to the form in the Book of Common Prayer—a duty which had been previously enjoined by canon 14 of 1603. By the Church Building Act 1818, the bishop may direct a third service, morning or evening, where necessary, in any church built under the act (s. 65). By the Church Building Act 1838, he may order the performance of two full services, each if he so direct to include a sermon (s. 8). The Burial Laws Amendment Act 1880, which authorizes burials in churchyards of the Church of England without the use of the funeral office of that church, does not allow such burials to take place on Sunday, Good Friday or Christmas Day if the parson of the church objects. Under the Metropolitan Police and Streets Acts, the Town Police Clauses Act 1841 and the Public Health Acts, street traffic may be regulated during the hours of divine service.

Constitutional.—Parliament has occasionally sat on Sunday in cases of great emergency, as on the demise of the Crown. Occasionally divisions in the House of Commons have taken place early on Sunday morning. The Ballot Act 1872 enacts that in reckoning time for election proceedings Sundays are to be excluded. A similar provision is contained in the Municipal Corporations Act 1882, as to proceedings under that act.

Judicial.—As a general rule Sunday for the purpose of judicial proceedings is a *dies non juridicus* on which courts of justice do not sit (9 Co. Rep. 66*b*). By s. 6 of the Sunday Observance Act 1677 legal process cannot be served or executed on Sunday, except in cases of treason, felony or breach of the peace. Proceedings which do not need the intervention of the court are good, *e.g.* service of a citation or notice to quit or claim to vote. By s. 4 of the Indictable Offences Act 1848 justice may issue a warrant of apprehension or a search warrant on Sunday. The rules of the Supreme Court provide that the offices of the Supreme Court shall be closed on Sundays, that Sunday is not to be reckoned in the computation of any limited time less than six days allowed for doing any act or taking any proceeding, and that, where the time for doing any act or taking any proceeding expires on Sunday, such act or proceeding is good if done or taken on the next day. In the divorce rules Sundays are excluded from compilation. In the county court rules they are excluded if the time limited is less than forty-eight hours, and the only county court process which can be executed on Sunday is a warrant of arrest in an Admiralty action. Where a time is fixed by statute, the Sundays are counted in. Where a term of imprisonment expires on Sunday, Christmas Day or Good Friday, the prisoner is entitled to discharge on the day next preceding (Prison Act 1898, s. 11).

Social.—Under this head may be grouped the enactments having for their object the regulation of Sunday travelling and amusements. The earliest example of non-ecclesiastical interference with recreation appears to be the *Book of Sports* issued by James I. in 1618. Royal authority was given to all but recusants to exercise themselves after evening service in dancing, archery, leaping, vaulting, May-games, Whitsun-ales, morris-dances and setting up of Maypoles; but bear and bull-baiting, interludes and bowling by the meaner sort were prohibited. The Sunday Observance Act 1625 (1 Car. I. c. 1), following the lines of the *Book of Sports*, inhibited meetings, assemblies or concourse of people out of their own parishes on the Lord's day for any sports and pastimes whatsoever, and any bear-baiting, bull-baiting, interludes, common plays or other unlawful exercises and pastimes used by any person or persons within their own parishes, under a penalty of 3s. 4d. for every offence. The right to enforce ecclesiastical censures is left untouched by the act. The act impliedly allows sports other than the excepted ones as long as only parishioners take part in them. In 1897 some lads were prosecuted at Streatley under this act for playing football in an adjoining parish, but the justices dismissed the charge, treating the act as obsolete. But in 1906 the Society for the Prevention of Cruelty to Animals instituted a prosecution under the act with the object of preventing extra-parochial rabbit-coursing on Sundays. The Game Act 1831 (1 & 2 Will. IV. c. 32, s. 3) makes it punishable to kill or take game, or to use a dog, net or other instrument (*e.g.* a snare), for that purpose on Sunday. The prohibition only applies to game proper and does not extend to rabbits.

There is no law in England against fishing on Sunday except as to salmon. Fishing for salmon on Sunday by any means other than a rod and line is prohibited by the Salmon Fishery Act 1861, and free passage for salmon through all cribs, &c., used for fishery is to be left during the whole of Sunday.

The Sunday Observance Act 1781 (21 Geo. III. c. 49), drawn by Dr Porteus, bishop of London, enacts that any place opened or used for public entertainment and amusement or for public debate upon any part of the Lord's day called Sunday, to which persons are admitted by payment of money or by tickets sold for money, is to be deemed a disorderly house. The keeper is to forfeit £200 for every day on which it is opened or used as aforesaid on the Lord's day, the manager or master of the ceremonies £100 and every doorkeeper or servant £50. The advertising or publishing any advertisement of such an entertainment is made subject to a penalty of £50. Proceedings under this act for penalties may be instituted by a common informer within six months of the offence. It was held in 1868 that a meeting the object of which was not pecuniary gain (though there was a charge for admission), but an honest intention to introduce religious worship, though not according to any established or usual form, was not within the act. The hall used was registered for religious worship. On this principle, forms of worship such as Mormonism or Mahommedanism are protected. In 1875 actions were brought against the Brighton Aquarium Company and penalties recovered under the act. As doubts were felt as to the power of the Crown to remit the penalties in such a case, an act was passed in 1875 to remove such doubts and to enable the sovereign to remit in whole or in part penalties recovered for offences against the act of 1781.

The substantive effect of the act is to hit all Sunday exhibitions or performances where money is charged for admission. In 1895 it was decided that the chairman of a meeting held to hear a lecture was not liable as manager of the meeting, and the solicitor of the liquidator of a company was held not to be liable for merely letting the hall for the meeting. In 1906 an attempt was unsuccessfully made to apply the act of 1781 to open-air meetings for rabbit-coursing. The rules for the government of theatres and places of public entertainment, and the terms of the licences issued, usually prohibit performances on Sundays. The lessees of certain places of public resort in London have in some cases obtained their licences from the London County Council on condition that they do not hold Sunday concerts, but the recent policy of the Council has been not to interfere with or restrict the giving of Sunday concerts unless they are given for private gain or by way of trade. The Council has no legal authority to dispense with the Sunday Observance Act 1781, which enforces penalties on giving entertainments to which persons are admitted by payment of money or by tickets sold for money. The law has been judicially interpreted, however, to mean that charges for reserved seats are not incompatible with free admission. In consequence of this ruling Sunday concerts have been regularly given at the Albert Hall, which is not under the licensing jurisdiction of the London County Council, and at the Queen's Hall and other places within that jurisdiction. No charge is made for admission, but those who wish for seats must pay for them, and the proceeds of the concerts are not made the subject of profit. At the licensing sessions conflicts have annually arisen on this subject between the advocates and opponents of Sunday music.

Bands play on Sundays in most of the parks in London, whether royal or under municipal control; and it is said that local authorities cannot make bylaws forbidding bands of music in the streets on Sunday (*Johnson* v. *Croydon Corporation*, 1886, 16 Q.B.D. 708). Libraries, museums and gymnasiums maintained by local authorities may, it would seem, be lawfully opened on Sundays, and the national galleries and museums are now so open for part of Sunday.

Commercial.—At common law a contract made on Sunday is not void, nor is Sunday trading or labour unlawful, and enlistment of a soldier on a Sunday has been held valid. At an early period, however, the legislature began to impose restrictions, at first by making Sunday trade impossible by closing the places of ordinary business, later by declaring certain kinds of trade and labour illegal, still later by attempting to prohibit all trade and labour. 28 Edw. III. c. 14 (1354, now repealed) closed the wool market on Sunday. An act of 1448 (27 Hen. VI. c. 5) prohibits fairs and markets on Sunday (necessary victual only excepted), unless on the four Sundays in harvest—an exemption repealed in 1850 (by 13 & 14 Vict. c. 23) 4 Edw. IV. c. 7 (1464 rep.) restrained the shoemakers of London from carrying on their business on Sunday. An act of 1627 (3 Car. I. c. 2) imposes a penalty of 20s. on any carrier, wagoner or drover travelling on the Lord's day, and a penalty of 6s. 8d. on any butcher killing or selling on that day. The act does not apply to stage coaches. Both this and the act of 1625 were originally passed only for a limited period, but by subsequent legislation they have become perpetual. Next in order is the Sunday Observance Act 1677 (29 Car. II. c. 7), "An act for the better observance of the Lord's day, commonly called Sunday."

After an exhortation to the observation of the Lord's day by exercises in the duties of piety and true religion, publicly and privately, the act provides as follows: No tradesman, artificer, workman, labourer or other person (*ejusdem generis*) whatsoever shall do or exercise any worldly labour, business or work of their ordinary callings upon the Lord's day or any part thereof (works of necessity and charity only excepted); and every person being of the age of fourteen years or upwards offending in the premises shall for every such offence forfeit the sum of 5s.; and no person or persons whatsoever shall publicly cry, show forth or expose to sale any wares, merchandises, fruit, herbs, goods or chattels whatsoever upon the Lord's day or any part thereof upon pain that every person so offending shall forfeit the same goods so cried, or showed forth, or exposed to sale (s. 1). A barber was held in 1900 not to be a tradesman, artificer, &c. within the act, and to be free to shave customers on Sunday[1]; nor is a farmer. No drover, horse-courser, wagoner, butcher, higgler or any of their servants, shall travel or come into his or their lodging upon the Lord's day or any part thereof, upon pain that each and every such offender shall forfeit 20s. for every such offence; and no person or persons shall use, employ or travel upon the Lord's day with any boat, wherry, lighter or barge, except it be upon extraordinary occasion to be allowed by some justice of the peace, &c., upon pain that every person so offending shall forfeit and lose the sum of 5s. for every such offence. In default of distress or non-payment of forfeiture or penalty the offender may be set publicly in the stocks for two hours (s. 2), a punishment now obsolete. Nothing in the act is to prohibit the dressing of meat in families, or the dressing or selling of meat in inns, cooks' shops—which include fried fish shops (*Bullen* v. *Ward*, 1905, 74 L.J.K.B. 916)—or victualling houses for such as cannot be otherwise provided, nor the crying or selling of milk before nine in the morning or after four in the afternoon (s. 3). Prosecutions must be within ten days after the offence (s. 4). The hundred is not responsible for robbery of persons travelling upon the Lord's day (s. 5). This act has frequently received judicial construction. The use of the word "ordinary" in section 1 has led to the establishment by a series of decisions of the principle that work done out of the course of the ordinary calling of the person doing it is not within the act. Thus the sale of a horse on Sunday by a horse-dealer would not be enforceable by him and he would be liable to the penalty, but these results would not follow in the case of a sale by a person not a horse-dealer. Certain acts have been held to fall within the exception as to works of necessity and charity, *e.g.* baking provisions for customers (but not baking bread in the ordinary course of business), running stage-coaches, or hiring farm-labourers. The legislature also intervened to obviate some of the inconveniences caused by the act. By 10 Will. III. c. 13 (1698) mackerel was allowed to be sold before and after service. By 11 Will. III. c. 21 (1699), forty watermen were allowed to ply on the Thames on Sunday. By 9 Anne, c. 23 (1710), licensed coachmen or chairmen might be hired on Sunday. By an act of 1794 (34 Geo. III. c. 61), bakers were allowed to bake and sell bread at certain hours. These acts are all repealed. Still law are the acts of 1762 (2 Geo. III. c. 15 s. 7), allowing fish carriages to travel on Sunday in London and Westminster; 1827 (8 Geo. IV. c. 75), repealing s. 2 of the act of 1677 as far as regards Thames boatmen. The Bread Acts of 1822 (3 Geo. IV. c. 106) allow bakers in London, and of 1836 (6 & 7 Will. IV. c. 37) allow bakers out of London, to carry on their trade up to 1.30 p.m. Since 1871, by an act annually continued (34 & 35 Vict. c. 87), no prosecution or proceeding for penalties under the act of 1677 can be instituted except with the consent in writing of the chief officer of a police district or the consent of two justices or a stipendiary magistrate, which must be obtained before beginning the prosecution, *i.e.* before applying for a summons (*Thorpe* v. *Priestnall*, 1897, 1, Q.B. 159). The act of 1871 does not apply to breaches of the Bread Acts (*R.* v. *Mead*, 1902, 2 K.B. 212).

A good many bills have been introduced with respect to Sunday trading. Most have been directed to the closing of public-houses on that day; but the Shop Hours Bill introduced in 1907 contained clauses for closing shops on Sundays, with the exception of certain specified trades. The result of the act of 1871 in London has been in substance to make the Lord's Day acts a dead letter as to Sunday trading. The commissioner of police rarely if ever allows a prosecution for Sunday trading. Sunday markets are usual in all the poorer districts, and shopkeepers and hawkers are allowed freely to ply their trades for the sale of eatables, temperance drinks and tobacco. But the conditions of licences for the sale of intoxicants and for refreshment houses are strictly enforced with respect to Sunday. In districts where the town councils have control of the police, prosecutions for Sunday trading are not infrequent; but they seem to be instituted rather from objection to the annoyance caused by street traders than from religious scruples. The limitation of the time for prosecution to ten days, and the necessity of the previous consent of the chief constable, have a great effect in restricting prosecutions. In most districts there is a distinct disposition to refrain from enforcing the strict letter of the older law, and to permit the latitude of what is described as the "Continental Sunday," except in the case of businesses carried on so as to interfere with the public comfort. In most districts liberality in administration has progressed *pari passu* with a change in public opinion as to the uses to which Sunday may properly be put; it is becoming less of a holy day and more of a holiday.

There is great activity among those interested in different theories as to the proper use of Sundays. On the one side, Lord's day observance societies and the organizations concerned in the promotion of "temperance" (*i.e.* of abstinence from alcoholic drinks) have been extremely anxious to enforce the existing law against Sunday trading and against the sale of intoxicants to persons other than bona fide travellers, and to obtain legislation against the sale of any alcohol on Sundays. On the other side, the Sunday League and other like organizations have been active to organize lectures and concerts and excursions on Sundays, and to promote so far as possible every variety of recreation other than attendance at the exercises of any religious body. Travelling and boating on Sunday are now freely resorted to, regardless of any restrictions in the old acts, and railway companies run their trains at all hours, the power to run them being given by their special acts. Tram-cars and omnibuses run freely on Sundays, subject only to certain restrictions. Hackney carriages may in London ply for hire on Sundays (1 & 2 Will. IV. c. 22).

Besides the general act of 1677, there are various acts dealing with special trades; of these the Licensing Acts and the Factory and Workshop Acts are the most important. By the Licensing Acts, 1872 and 1874, premises licensed for the sale of intoxicating liquors by retail are to be open on Sunday only at certain hours, varying according as the premises are situate in the metropolitan district, a town or populous place, or elsewhere. The hours may be varied to fit in with the hours of religious worship in the district. An exception is made in favour of a person lodging in the house or a bona fide traveller, who may be served with refreshment during prohibited hours, unless in a house with a six-day licence. In the case of six-day licences, no sale of liquor may be made except to persons lodging in the house. Attempts have often been made to induce the legislature to adopt the principle of complete Sunday closing in England as a whole, or in particular counties.[2] In the session of 1886 a bill for Sunday closing in Durham was passed by the Commons but rejected by the Lords. The advocates of Sunday closing in Wales have been more successful. The Sunday Closing (Wales) Act 1881 contains no exceptions of towns and the only exemption is the sale of intoxicating liquors at railway stations. Public billiard tables may not be used on Sunday (8 & 9 Vict. c. 109). The Factory and Workshop Act (1901) forbids the employment of women, young persons or children on Sunday in a factory or workshop (s. 34). But a woman or young person of the Jewish religion may be employed on Sunday by a Jewish manufacturer if he keeps his factory or workshop closed throughout Saturday, and does not open it for traffic on Sunday, and does not avail himself of the exceptions authorizing employment of women or young persons on Saturday evening or for an additional hour on other weekdays (ss. 47, 48). There are a few other legislative provisions of less importance which may be noticed. Carrying on the business of a pawnbroker on Sunday is an offence within the Pawnbrokers Act 1872. Distilling and rectifying spirits on Sunday is forbidden by the Spirits Act 1880. The effect of Sunday upon bills of exchange is declared by the Bills of Exchange Act 1882. A bill is not invalid by reason only of its bearing date on a Sunday (s. 13). Where the last day of grace falls on a Sunday, the bill is payable on the preceding business day (s. 14). Sunday is a "non-business day" for the purposes of the act (s. 92).

Scotland.—The two earliest acts which dealt with Sunday are somewhat out of harmony with the general legislation on

[1] It is curious that by an order in council of Hen. VI. to regulate the sanctuary of St Martin-le-Grand it was provided that all artificers dwelling within the said sanctuary (as well barbers as others) keep holy the Sundays and other great festival days without breach or exercising their craft as do the citizens of London (Gomme, *Governance of London*, 1907, p. 329).

[2] The act 1 James I. c. 9 (now repealed) appears, however, to have provided for closing ale-houses in most cases, except on usual working days.

the subject. That of 1457, c. 6, ordered the practice of archery on Sunday; that of 1526, c. 3, allowed markets for the sale of flesh to be held on Sunday at Edinburgh. Then came a long series of acts forbidding the profanation of the day, especially by salmon-fishing, holding fairs and markets, and working in mills and salt-pans. The act of 1579, c. 70, and 1661, c. 18, prohibit handy labouring and working, and trading on the Sabbath. Under the act of 1579 the House of Lords in 1837 held that it was illegal for barbers to shave their customers on Sundays, although the deprivation of a shave might prevent decently disposed men from attending religious worship, or associating in a becoming manner with their families and friends through want of personal cleanliness. The later legislation introduced an exception in favour of duties of necessity and mercy, in accordance with ch. 21 of the Confession of Faith (1690, c. 5).

In more modern times the exigencies of travelling have led to a still further extension of the exception. In these acts the word Sabbath is generally used as in the Commonwealth ordinances. The Sabbath Observance Acts were frequently confirmed, the last time by the Scots parliament in 1696. The Scottish Episcopalians Act 1711 (10 Anne, c. 10) contains a proviso that all the laws made for the frequenting of divine service on the Lord's day commonly called Sunday shall be still in force and executed against all persons who shall not resort either to some church or to some congregation or assembly of religious worship allowed and permitted by this act. The Scots acts were held by the High Court of Justiciary in 1870 to be still subsisting, as far as they declare the keeping open shop on Sunday to be an offence by the law of Scotland (Bute's Case, 1 Couper's *Reports*, 495), but all except those of 1579 and 1661 above specified were repealed in 1906. The Licensing (Scotland) Act 1903 provides by the scheduled forms of certificate for the closing on Sunday of public-houses, and places licensed for the sale of excisable liquor, and in the case of inns and hotels forbids the sale of intoxicants except for the accommodation of lodgers or travellers. There has been litigation as to the legality of running tram-cars on the Sabbath.

By the Herring Fishery (Scotland) Act 1815, s. 11, herring nets set or hauled on the coast or within two leagues thereof on Sundays are forfeited. By the Salmon Fisheries (Scotland) Act 1868, s. 15, fishing for salmon on Sunday, even with a rod and line, is an offence, as is taking or attempting to take or assisting in fishing for salmon.

As to contracts and legal process, the law is in general accordance with that of England. Contracts are not void, apart from statute, simply because they are made on Sunday. Diligence cannot be executed but a warrant of imprisonment or *meditatio fugae* is "exercisable."

Ireland.—In Ireland an act of 1695 (7 Will. III. c. 17) covers the same ground as the English act of 1677, but the acts referred to under England do not apply. An act of 1851 (14 & 15 V. c. 93, s. 11) provides for the issue and execution of warrants for indictable offences and search-warrants on Sundays. But proceedings to obtain sureties for the peace taken on Sunday are void. The Irish act of 1787 against killing game on Sunday (27 Geo. III. c. 35, s. 4) includes rabbits and quail, landrail or other wild fowl. The Sunday closing of public-houses with exemptions as to certain cities and as to railway stations, packet-boats and canteens, is enforced by legislation of 1878, continued annually until 1906 and then made perpetual with certain modifications (1906, c. 39, s. 1), and in the case of six-day licences by acts of 1876, 1877 and 1880.

In 1899 a race-course used for Sunday racing was closed by injunction as causing a nuisance to the Sunday peace and quiet of the neighbourhood and the services of the adjacent churches.

Where railway trains are run on Sundays one cheap train each way is to be provided (7 & 8 Vict. c. 85, s. 10; repealed in 1883 as to Great Britain).

British Colonies.—The English law as to Sunday observance was the original law of the colonies acquired by settlement, and in many of them so much of it as does not relate to the Church of England is left to operate without colonial legislation. In other colonies it is supplemented or superseded by colonial acts. Canada has an act (No. 27 of 1906) prohibiting all buying and selling and all exercise by a man of his ordinary vocations or business, either by himself or his employees on the Lord's day, except in case of works of necessity or mercy. In New Zealand an act of 1884 (c. 24, s. 16; amended 1906, c. 36) prohibits the carrying on on Sunday of any trade or calling, but the exceptions are numerous, and, besides works of necessity or charity, include driving live stock, sale of medicines, sale or delivery of milk, hairdressing or shaving before 9 a. m., driving public or private carriages, keeping livery stables, working railways, ships and boats, and letting boats for hire, and work in connexion with post offices and telegraphs and with daily newspapers. (W. F. C.)

Foreign Countries.—Consequent on the introduction of a Weekly Rest Day Bill (which obtained a second reading) in the English House of Lords in 1908, a parliamentary paper was published in 1909 (cd. 4468) containing "Reports from His Majesty's Representatives Abroad as to Legislation in Foreign Countries Respecting a Weekly Rest Day." The principal points are summarized below:—

Austria.—Legislation is embodied in laws of 1895 and 1905, which prohibit any industrial work on Sunday, rest on that day beginning not later than 6 a.m., and lasting for not less than twenty-four hours. Permission is given for absolutely necessary work, provided the employer submits to the authorities a list giving the names of the persons employed, and the place, duration and nature of their employment. Sunday work is permitted in certain industries. As to buying and selling, Sunday trading is permitted for not more than four hours, local authorities being the power for arranging the time; they may also forbid Sunday trading altogether, if they think it necessary. Traders who do not employ workmen may not work for themselves unless the doors by which the public may enter are closed. On feast-days, employees must, according to their respective religious beliefs, be allowed the necessary time for attendance at morning service. Offences are punishable by fine; a warning, however, is given on the first offence, and the fine (4s. 2d. for the first offence) rises for each subsequent offence.

Belgium.—Laws of 1905 and 1907 forbid work on Sunday to persons engaged in industrial and commercial enterprises, with certain exceptions, such for example, as industries which exist only at certain periods of the year, or which have a press of work at certain times, or open-air industries which depend on the weather.

Denmark.—The only legislation is a law of 1904 concerning the public peace on the National Church holidays and Constitution Day. It forbids all kinds of occupations, which, on account of noise, might disturb the holiday's peace. In the large towns carriage traffic for business purposes is also forbidden after 10 a.m.

France.—A law of the 13th of July 1906 established a weekly day of rest, for every workman or employee of not less than twenty-four consecutive hours. The weekly day of rest must be Sunday. The law applies irrespective of the duration or character of the work done, and to employees in all establishments of a commercial or industrial character. There are certain necessary exceptions, such as shops for retailing food, occupations in which place, season, the habits of the public, &c., make observance impossible, and in such the weekly day of rest must be given in rotation to the employees or a compensating holiday instead.

Germany.—Regulations as to Sunday rest are contained in the Trade Regulations (*Gewerbeordnung*) of the 26th of July 1900, according to which manufacturers cannot compel workmen to work on Sundays or holidays, except in certain cases of necessity. Nor in trading businesses may assistants, apprentices or workmen be employed at all on Christmas Day, Easter Sunday and Whitsunday, or on other Sundays and holidays more than five hours. The regulations do not apply to hotels, cafés, &c., or to theatres or other places of amusement, or to means of communication. Infringement of the regulations is punishable by a fine, not exceeding 600 marks or by imprisonment.

Hungary.—By a law of 1891 and others of 1903 and 1908 all industrial work is prohibited on Sundays and St Stephen's Day (the patron saint of Hungary). Certain categories of industries are exempted on account of necessity or the needs of the consuming public; independent small craftsmen who work at home without assistants are also exempted. The law is enforced by the police authorities and infringement is punished by fine.

Italy.—A weekly rest day has been enacted by a law of the 7th of July 1907. Exceptions to the law are river, lake and maritime navigation; agricultural, hunting and fishing industries; state railways and tramways and state public services and industrial undertakings.

Other European countries which have legislation are the Netherlands (law of 1889, as amended by a law of 1906; Spain (law of March 1904, Regulations of April 1905); and Switzerland (1906).

United States.—In the United States there is no Federal law, the question of a rest day being left entirely to the state legislatures, consequently "there exists considerable diversity of legislation on the subject, ranging from the old Quaker laws of the state of Pennsylvania of the beginning of the 18th century to the modern regulations of the Far Western agricultural and mining states . . . There is no state, however, where it is specifically laid down that an employee who is forced to work on Sunday shall receive another equivalent day of rest." (*Report of H.M. Ambassador to the U.S. vide supra*). In Massachusetts, which may be fairly taken as representing the Eastern states, public service corporations, such as railway, street railway, steamboat, telegraph, telephone, electric lighting, water and gas companies, are permitted to serve the public in the usual manner. Public parks and baths are open. Tobacco may be sold by licensed innholders, common victuallers, druggists and newsdealers. Bake shops may be open during certain hours. All other shops must be closed. Saloons are closed, and liquor can be served only to the guests of licensed innholders. Horses, carriages, boats and yachts may be let for hire. All games and entertainments, except licensed sacred concerts, are prohibited. In Connecticut Sunday recreation is still prohibited, but electric and steam cars are allowed to run. Sunday is a close time for game and birds (1899). In many of the Western states base-ball, games and various entertainments for pay are permitted, and in some saloons are open. In many but not all the states such persons as by their religion are accustomed to observe Saturday are allowed to pursue their ordinary business on Sunday. In Delaware and Illinois barbers may not shave customers on Sundays; and in Georgia guns and pistols may not be fired (1898). In North Dakota the fines for Sabbath-breaking have been raised.

SUNDERLAND, CHARLES SPENCER, 3RD EARL OF (*c.* 1674–1722), English statesman, was the second son of the 2nd earl, but on the death of his elder brother Henry in Paris in September 1688 he became heir to the peerage. Called by John Evelyn "a youth of extraordinary hopes," he completed his education at Utrecht, and in 1695 entered the House of Commons as member for Tiverton. In the same year he married Arabella, daughter of Henry Cavendish, 2nd duke of Newcastle; she died in 1698 and in 1700 he married Anne Churchill, daughter of the famous duke of Marlborough. This was an important alliance for Sunderland and for his descendants; through it he was introduced to political life and later the dukedom of Marlborough came to the Spencers. Having succeeded to the peerage in 1702, the earl was one of the commissioners for the union between England and Scotland, and in 1705 he was sent to Vienna as envoy extraordinary. Although he was tinged with republican ideas and had rendered himself obnoxious to Queen Anne by opposing the grant to her husband, Prince George, through the influence of Marlborough he was foisted into the ministry as secretary of state for the southern department, taking office in December 1706. From 1708 to 1710 he was one of the five whigs, called the Junta, who dominated the government, but he had many enemies, the queen still disliked him, and in June 1710 he was dismissed. Anne offered him a pension of £3000 a year, but this he refused, saying "if he could not have the honour to serve his country he would not plunder it."

Sunderland continued to take part in public life, and was active in communicating with the court of Hanover about the steps to be taken in view of the approaching death of the queen. He made the acquaintance of George I. in 1706, but when the elector became king the office which he secured was the comparatively unimportant one of lord-lieutenant of Ireland. In August 1715 he joined the cabinet as lord keeper of the privy seal, and after a visit to George I. in Hanover he secured in April 1717 the position of secretary of state for the northern department. This he retained until March 1718, when he became first lord of the treasury, holding also the post of lord president of the council. He was now prime minister. Sunderland was especially interested in the proposed peerage bill, a measure designed to limit the number of members of the House of Lords, but this was defeated owing partly to the opposition of Sir Robert Walpole. He was still at the head of affairs when the South Sea bubble burst and this led to his political ruin. He had taken some part in launching the scheme of 1720, but he had not profited financially by it; however, public opinion was roused against him and it was only through the efforts of Sir Robert Walpole that he was acquitted by the House of Commons, when the matter was investigated. In April 1721 he resigned his offices, but he retained his influence with George I. until his death on the 19th of April 1722.

Sunderland inherited his father's passion for intrigue, while his manners were repelling, but he stands high among his associates for disinterestedness and had an alert and discerning mind. From his early years he had a great love of books, and he spent his leisure and his wealth in forming the library at Althorp, which in 1703 was described as "the finest in Europe." In 1749 part of it was removed to Blenheim.

The earl's second wife having died in April 1716, after a career of considerable influence on the political life of her time, in 1717 he married an Irish lady of fortune, Judith Tichborne (d. 1749). By Lady Anne Churchill he had three sons and two daughters. Robert (1701–1729), the eldest son, succeeded as 4th earl, and Charles (1706–1758), the second son, became the 5th earl. In 1733 Charles inherited the dukedom of Marlborough and he then transferred the Sunderland estates to his brother John, father of the 1st Earl Spencer (see MARLBOROUGH, EARLS AND DUKES OF).

For the career of Sunderland see W. Coxe, *Memoirs of Marlborough* (1847–1848); Earl Stanhope, *History of England* (1853), and I. S. Leadam, *Political History of England, 1702–1760* (1909).

SUNDERLAND, ROBERT SPENCER, 2ND EARL OF (1640–1702), English politician, was the only son of Henry Spencer (1620–1643), who succeeded his father, William, as 3rd Baron Spencer of Wormleighton in 1636. This barony had been bestowed in 1603 upon Sir Robert Spencer (d. 1627), the only son of Sir John Spencer (d. 1600) of Althorp, Northamptonshire, who claimed descent from the baronial family of Despenser. The fortunes of the family were founded by Sir John Spencer (d. 1522) of Snitterfield, Warwickshire, a wealthy grazier. His descendant, Sir Robert Spencer, the 1st baron, was in 1603, "reputed to have by him the most money of any person in the kingdom." Sir Robert's grandson, Henry, the 3rd baron, was created earl of Sunderland in June 1643, and was killed at the battle of Newbury when fighting for the king a little later in the same year. He married Dorothy (1617–1684), daughter of Robert Sidney, 2nd earl of Leicester. She was the *Sacharissa* of the poems of her admirer, Edmund Waller, and for her second husband she married Sir Robert Smythe. Their son Robert, the 2nd earl, was educated abroad and at Christ Church, Oxford, and in 1665 married Anne (d. 1715), daughter of John Digby, 3rd earl of Bristol; she was both a beauty and an heiress, and is also famous for her knowledge and love of intrigue. Having passed some time in the court circle, Sunderland was successively ambassador at Madrid, at Paris and at Cologne; in 1678 he was again ambassador at Paris. In February 1679, when the country was agitated by real or fancied dangers to the Protestant religion, the earl entered political life as secretary of state for the northern department and became at once a member of the small clique responsible for the government of the country. He voted for the exclusion of James, duke of York, from the throne, and made overtures to William, prince of Orange, and consequently in 1681 he lost both his secretaryship and his seat on the privy council. Early in 1683, however, through the influence of the king's mistress, the duchess of Portsmouth, Sunderland regained his place as secretary for the northern department, the chief feature of his term of office being his rivalry with his brother-in-law, George Savile, marquess of Halifax. By this time he had made his peace with the duke of York, and when in February 1685 James became king, he retained his position of secretary, to which was soon added that of lord president of the council. He carried out the wishes of the new sovereign and after the intrigues of a few months he had the satisfaction of securing the dismissal of Lawrence Hyde, earl of Rochester, from his post as lord treasurer. He was a member of the commission for ecclesiastical causes, and although afterwards he claimed that he had used all his influence to dissuade James from removing the tests, and in other ways illegally favouring the Roman Catholics, he signed the warrant for the committal of the seven bishops, and appeared as a witness against them. It should be mentioned that while Sunderland was thus serving James II., he was receiving a pension from France, and through his wife's lover, Henry Sidney, afterwards earl of Romney, he was furnishing William of Orange with particulars about affairs in England.

In the last months of James's reign he was obviously uncomfortable. Although he had in 1687 openly embraced the Roman Catholic faith, he hesitated to commit himself entirely to the acts of the fierce devotees who surrounded the king, whom he advised to reverse the arbitrary acts of the last year or two, and in October 1688 he was dismissed by James with the remark "I hope you will be more faithful to your next master than you have been to me."

Sunderland now took refuge in Holland, and from Utrecht he sought to justify his recent actions in *A letter to a friend in the country*. He had been too deeply involved in the arbitrary acts of James II. to find a place at once among the advisers of William and Mary, and he was excepted from the act of indemnity of 1690. However, in 1691, he was permitted to return to England, and he declared himself a Protestant and began to attend the sittings of parliament. But his experience was invaluable and soon he became prominent in public affairs, a visit which William III. paid him at Althorp, his Northamptonshire seat, in 1691, being the prelude to his recall into the royal counsels. It was his advice which led the king to choose all his ministers from one political party, to adopt the modern system, and he managed to effect a reconciliation between William and his sister-in-law, the princess Anne. From April to December 1697 he discharged the duties of lord chamberlain, and for part of this time he was one of the lords justices, but the general suspicion with which he was regarded terrified him, and in December he resigned. The rest of his life was passed in seclusion at Althorp, where he died on the 28th of September 1702. The earl was a great gambler, but he was wealthy enough also to spend money on improving his house at Althorp, which he beautified both within and without. His only surviving son was Charles Spencer, 3rd earl of Sunderland (*q.v.*).

Lord Sunderland possessed a keen intellect and was consumed by intense restlessness; but his character was wanting in steadfastness, and he yielded too easily to opposition. His adroitness in intrigue and his fascinating manners were exceptional even in an age when such qualities formed part of every statesman's education; but the characteristics which ensured him success in the House of Lords and in the royal closet led to failure in his attempts to understand the feelings of the mass of his countrymen. Consistency of conduct was not among the objects which he aimed at, nor did he shrink from thwarting in secret a policy which he supported in public. A large share of the discredit attaching to the measures of James II. must be assigned to the earl of Sunderland.

The best account of Sunderland is the article by T. Seccombe in the *Dict. Nat. Biog.*, which gives a full bibliography.

SUNDERLAND, a seaport and municipal, county and parliamentary borough of Durham, England, at the mouth of the river Wear, on the North-Eastern railway, 261 m. N. by W. from London. Pop. (1891), 131,686; (1901) 146,077. The borough includes the township of Bishopwearmouth, to the south of Sunderland proper, which lies on the south bank of the river; and that of Monkwearmouth, on the north bank. Adjacent to Monkwearmouth on the north-west is the extensive urban district of Southwick, within the parliamentary borough. A great cast-iron bridge crosses the river with a single span of 236 ft. and a height of 100 ft. above low water. It was designed by Rowland Burdon, opened in 1796, and widened under the direction of Robert Stephenson in 1858. The only building of antiquarian interest is the church of St Peter, Monkwearmouth, in which part of the tower and other portions belong to the Saxon building attached to the monastery founded by Benedict Biscop in 674. The church of St Michael, Bishopwearmouth, is on an ancient site, but is a rebuilding of the 19th century. There is a large park at Roker on the north-east of the town, a favourite seaside resort, and (among other parks) that at Bishopwearmouth contains a bronze statue of Sir Henry Havelock, who was born (1795) at Ford Hall in the neighbourhood.

The prosperity of Sunderland rests on the coalfields of the neighbourhood, the existence of which gave rise to an export trade in the reign of Henry VII., which has grown to great importance. Manufacturing industries include shipbuilding, iron and steel works, engineering, anchor and chain cable, glass and bottle and chemical works and paper mills. Limestone is largely worked. For 5 m. above its mouth the Wear resembles on a reduced scale the Tyne in its lower course. The harbour is constantly undergoing improvement. The docks cover an area of upwards of 200 acres, and there are several graving docks up to 441 ft. in length. The parliamentary borough returns two members. The municipal borough is under a mayor, 16 aldermen and 42 councillors, and has an area of 3357 acres.

The history of Sunderland is complicated by the name Wearmouth (*Wiramuth*, *Wermuth*) being applied impartially to the Monk's town on the north bank of the Wear; the Bishop's town on the south and the neighbouring port now known as Sunderland. In both Monk's and Bishop's Wearmouth the settlement was connected with the church. Benedict Biscop in 674 obtained from Ecgfrith king of Northumbria seventy hides of land on the north bank of the river, on which he founded the Benedictine monastery of St Peter. Not more than a year after the foundation Benedict brought over skilled masons and glass-workers from Gaul who wrought his church in the Roman fashion, the work being so speedily done that Mass was celebrated there within the year. A subsequent visit to Rome resulted in a letter from Pope Agatho exempting his monastery from all external control. Later Benedict acquired three hides on the south side of the river. The abbey, where Bede was educated, was destroyed by the Danes and probably not rebuilt until Bishop Walcher (1071–1081) settled Aldwin and his companions there. They found the walls in ruins from the neglect of 208 years, but the church was soon rebuilt. Bishop William of St Carileph (1081–1099), desiring to acquire the possessions of the house for his new foundation of Durham, transferred the monks there, Wearmouth becoming henceforward a cell of the larger house. Meanwhile Bishop's Wearmouth was becoming important, having been granted to the bishops by Æthelstan in 930. As a possession of the see it is mentioned in Boldon Book in conjunction with Tunstall as an ordinary rural vill rendering one milch cow to the bishop, while the demesne and its mill rendered £20, the fisheries £6 and the borough of Wearmouth 20s. There seems no doubt but that the borough, identical with that to which Bishop Robert de Pinset granted his charter, was in reality Sunderland, the name Wearmouth being used to cover Bishop's and Monk's Wearmouth and the modern Sunderland. It was from Wearmouth that Edgar Ætheling set sail for Scotland, the account implying that this was a frequented port. In 1197 the town of Wearmouth rendered 37s. 4d. tallage during the vacancy of the see, and in 1306–1307 the assessment of a tenth for Bishop's Wearmouth was £5, 5s. 4d., while that of Monk's Wearmouth was £1, 6s. 8d. Probably the northern town remained entirely agricultural, while the shipping trade of Bishop's Wearmouth was steadily increasing. In 1382 what was probably a dock there rendered 2s., and in 1385 the issues of the town were worth £45, 9s. 2d. annually. In 1431 the rent of assize from the demesne lands of Monk's Wearmouth was £5, 1s. 0d. A further contrast is shown by the number of houseling persons, or those who received the sacrament, returned in 1548: Bishop's Wearmouth had 700 and Monk's Wearmouth 300. From this time, at least, Bishop's Wearmouth seems to have been completely identified with Sunderland: in 1567 Wearmouth was one of the three ports in Durham where precautions were to be taken against pirates, while no mention is made of Sunderland. Monk's Wearmouth remained purely agricultural until 1775, when a shipbuilding yard was established and prospered to such an extent that by 1795 five similar yards were at work.

The Boldon Book states that Sunderland was at farm in 1183 and rendered 100 shillings and the town of Sunderland rendered 58 shillings tallage in 1197 during the vacancy of the see. In 1382 Thomas Menvill held the borough, which with its yearly free rent, courts and tolls was worth £1, 12s. 8d. Edward IV. in 1464, sede vacante, granted a lease of the borough, and in 1507, Cardinal Bainbridge granted it by copyhold at a rent of £6, which dropped to £4 in 1590. Bishop Morton incorporated Sunderland in 1634, stating that it had been a borough from time immemorial under the name of the New Borough of Wearmouth. This charter lapsed during the Civil Wars, when the borough was sold with the manor of Houghton-le-Spring for £2851, 9s. 6d. Nevertheless the inhabitants retained their rights. Sunderland became a parliamentary borough returning two members in 1834. The charter of 1634 granted a market and annual fair which are still held. The charter of Bishop Hugh provided for pleas between burgesses and foreign merchants, and directed that merchandise brought by sea should be landed before sale, except in the case of salt and herrings. Bishop Hatfield gave a lease of the fisheries in 1358. In the 15th century commissions were held touching salmon-fisheries and obstructions in the Wear, while Bishop Barnes (1577–1587) appointed a water-bailiff for the port, and licensed the building of wharves for the sale of coal. During the 17th century Sunderland was the seat of a vice-admiralty court for the county palatine and in 1669 letters patent permitted the erection of a pier and lighthouse as the harbour was "very commodiously situate for the shipping of vast quantities of sea-coles plentifully gotten and wrought there."

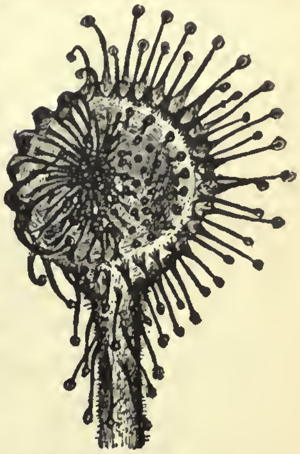
SUNDEW, in botany, the popular name for a genus of plants known as *Drosera* (Gr. *δρόσος*, dew; Fr. *rossolis*, Ger. *Sonnenthau*) so called from the drops of viscid transparent glittering secretion borne by the tentacles which cover the leaf-surface. It is a cosmopolitan genus of slender glandular herbs, with leaves arranged in a basal rosette or alternately on an elongated stem, and is represented in Britain by three species, which are found in spongy bogs and heaths.

The common sundew (*D. rotundifolia*) has extremely small roots, and bears five or six radical leaves horizontally extended in a rosette around the flower-stalk. The upper surface of each leaf is covered with gland-bearing filaments or "tentacles," of which there are on an average about two hundred. Each gland is surrounded by a large dew-like drop of the viscid secretion. A small fibro-vascular bundle (*b*, fig. 3, B), consisting mainly of spiral

(After Darwin.)

FIG. 1.—Leaf of Sundew (*Drosera rotundifolia*). (× 4.)

vessels, runs up through the stalk of the tentacle and is surrounded by a layer of elongated parenchyma cells outside of which is the epidermis filled with a homogeneous fluid tinted purple by a derivative of chlorophyll (eryhrophyll). The epidermis bears small multicellular prominences. The glandular head of the tentacle contains a central mass of spirally thickened cells (tracheïds) in immediate contact with the upper end of the fibrovascular bundle. Around these is a layer of large colourless thin walled cells which reaches the surface at the base of the head and acts as absorbing cells. Outside these are two layers (the outer one the epidermis) filled with purple fluid.

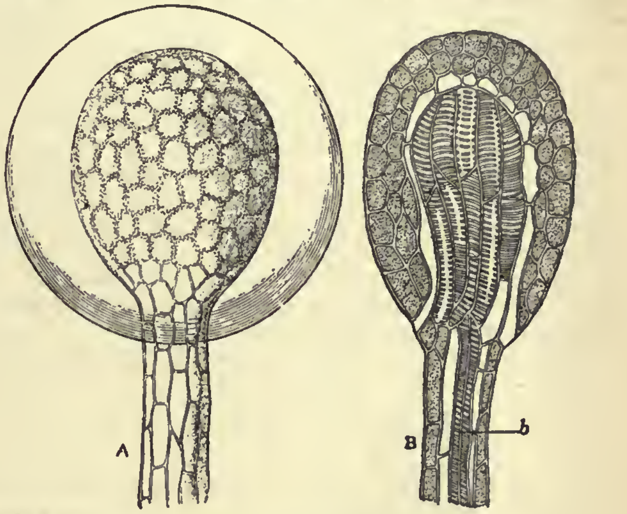


After Darwin.

FIG. 2.—Leaf of Sundew, enlarged, with the tentacles on one side inflected over a bit of meat placed on the disk.

Insects are attracted by the leaves; a fly alighting on the disk, or even only touching one or two of the exterior tentacles, is immediately entangled by the viscid secretion; the tentacles to which it is adhering begin to bend, and thus pass on their prey to the tentacles next succeeding them inwards, and the insect is thus carried by a curious rolling movement to the centre of the leaf. The tentacles on all sides become similarly inflected; the blade or the leaf may even become almost cup-shaped; and the insect, bathed in the abundant secretion which soon closes up its tracheae, is drowned in about a quarter of an hour. The leaves clasp also, but for a much shorter time, over inorganic bodies.

The bending of the tentacle takes place near its base, and may be excited (1) by repeated touches, although not by gusts of wind or drops of rain, thus saving the plant from much useless movement; (2) by contact with any solid, even though insoluble and of far greater minuteness than could be appreciated by our sense of touch—a morsel of human hair weighing only $\frac{1}{78740}$ of a grain, and this



(After Dodel-Port.)

FIG. 3.—Glands of Sundew magnified.
A, External aspect with drop of secretion; B, Internal structure.

largely supported too by the viscid secretion, sufficing to induce movement; (3) by the absorption of a trace of certain fluids, mostly nitrogenous. During the inflexion of the tentacle, and even before it touches the stimulating object, the secretion of the gland increases in quantity, and, instead of remaining neutral, becomes acid. The secretion contains a digestive enzyme which renders soluble the nitrogenous substances of the insect's body; these are then absorbed through thin-walled cells at the base of the gland. After absorption the tentacles recurve and the leaf assumes its normal appearance.

FIG. 4.—Part of Leaf of *Drosophyllum lusitanicum.* (× 7.)

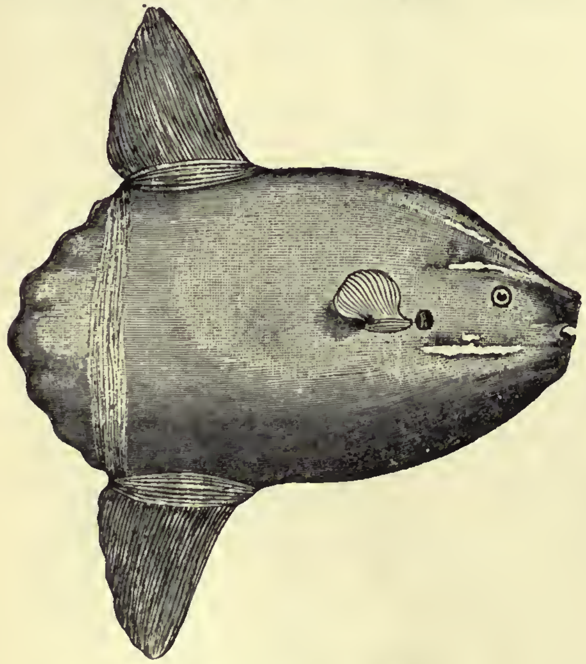
Closely allied to *Drosera* is *Drosophyllum lusitanicum*, which catches such vast numbers of flies in a state of nature that the Portuguese cottagers call it the fly-catcher, and hang up branches of it in their houses for this purpose. Its long narrow leaves are thickly covered with stalked glands, which resemble in the main the tentacles of *Drosera*, save in that they are incapable of movement, and that the secretion is less viscid and freely leaves the gland to wet the insect, which, creeping onward, soon clogs its wings and dies. There are, moreover, many minute colourless sessile glands, which, when stimulated by the absorption of nitrogenous matter, excrete an acid digestive secretion similar to that of the sundew, by means of which the body of the captured insect is digested and absorbed.

SUNDSVALL, a seaport of Sweden in the district (*län*) of Vesternorrland, on a wide bay of the Baltic, at the north of the Selånger River, 360 m. N. by W. of Stockholm, the terminus of a branch from Ange on the northern railway. Pop. (1900), 14,831. It was rebuilt in brick and stone after a destructive fire in 1888. In the town and its vicinity are numerous steam saw-mills, besides wood-pulp factories, steelworks, brickworks, engineering shops, breweries and joineries, but Sundsvall owes its chief importance to its export trade in timber (6 to 7 million cub. ft. annually), the bulk of which goes to Germany, France and Great Britain. It also exports wood-pulp, iron and fish. There is a special trade with Finland. The harbour, which is usually closed by ice from about the middle of December to the second week in May, is sheltered against the east winds by a group of islands.

SUNFISH, a name chiefly and properly applied to a marine fish (*Orthagoriscus*) of the order Plectognathi, which by its large size, grotesque appearance and numerous peculiarities of organization has attracted the attention equally of fishermen as of naturalists. Only two species are known, the rough or short sunfish (*O. mola*), which is found in all seas of the temperate and tropical zones; and the smaller and scarcer smooth or oblong sunfish (*O. truncatus*), of which only a small number of specimens have been obtained from the Atlantic and Indian oceans.

Sunfishes have the appearance of tailless fish. This is due to the extreme shortening of the caudal region which is supported by only a few short vertebrae; the caudal fin is absent, what appears to be a tail being formed by the confluence of dorsal and ventral fins: pelvic fins are also wanting. The anterior parts of the dorsal and ventral fins are high and broad, similar to each other in size and triangular in form. The head is completely merged in the trunk, the boundary between them being indicated only by a very small and narrow gill-opening and a comparatively small pectoral fin. This fin can be of but little use in locomotion, and the horizontal and vertical movements of the fish, as well as the maintenance of its body in a vertical position, are evidently executed by the powerful dorsal and anal fins. The small mouth, situated in front of the head, is armed with an undivided dental plate above and below, similar to but weaker than the teeth of the globe-fish (*Diodon*).

Sunfishes are truly pelagic, propagating their species in the open sea, and only occasionally approach the coast. During the stormy season they live probably at some depth, but in calm, bright weather they rise and rest or play on the surface with their dorsal fin high above the water. This habit has given rise to the popular name "sunfish," a term also sometimes applied to the basking-shark. In some years the rough sunfish is by no means scarce on the south coast of England and on the Irish coasts, where it appears principally in the summer months. The usual size is from 3 to 4 ft. in length, but this species attains to 7 ft. and more. One of the largest specimens (shown in the figure) was caught near Portland (Dorsetshire) in 1846, and is now in the British Museum; its length is 7 ft. 6 in. The sunfish has no economic value, and is rarely, if ever, eaten.



Sunfish (*Orthagoriscus mola*).

Whilst the rough sunfish has a granulated, rough, shagreen-like skin, the second species (*O. truncatus*) has the surface of the body smooth and polished, with its small dermal scutes arranged in a tesselated fashion. It is oblong in shape, the body being much longer than it is deep. The sides are finely ornamented with transverse silvery, black-edged stripes running downwards to the lower part of the abdomen. It has not been found to exceed 2 ft. in length. Only a few specimens have been captured on the coasts of Europe, at the Cape of Good Hope and off Mauritius.

SUNFLOWER. The common sunflower, known botanically as *Helianthus annuus*, a member of the natural order Compositae, is a native of the western United States. It is an annual herb with a rough hairy stem 3 to 12 ft. high, broad coarsely toothed rough leaves 3 to 12 in. long, and heads of flowers 3 to 6 in. wide in wild specimens and often a foot or more in cultivated. Double forms are in cultivation, one (*globosus fistulosus*) having very large globular heads. The plant is valuable from an economic as well as from an ornamental point of view. The leaves are used as fodder, the flowers yield a yellow dye, and the seeds contain oil and are used for food. It is cultivated in Russia and other parts of Europe, in Egypt and India and in several parts of England hundreds of plants are grown on sewage farms for the seeds. The yellow sweet oil obtained by compression from the seeds is considered equal to olive or almond oil for table use. Sunflower oilcake is used for stock and poultry feeding, and largely exported by Russia to Denmark, Sweden and elsewhere. The genus *Helianthus* contains about fifty species, chiefly natives of North America, a few being found in Peru and Chile. They are tall, hardy annual or perennial herbs, several of which are well known in gardens where they are of easy cultivation in moderately good soil. *H. decapetalus* is a perennial about 5 ft. high with solitary heads about 2 in. across in slender twiggy branchlets; *H. multiflorus* is a beautiful species with several handsome double varieties; *H. orygalis* is a graceful perennial 6 to 10 ft. high, with drooping willow-like leaves and numerous comparatively small yellow flower-heads. *H. atrorubens*, better known as *Harpalium rigidum*, is a smaller plant, 2 to 3 ft. high, the flower heads of which have a dark red or purple disk and yellow rays. There are many fine forms of this now, some of which grow 6 to 9 ft. high and have much larger and finer flowers than the type. Other fine species are *H. giganteus*, 10 to 12 ft.; *H. laetiflorus*, 6 to 8 ft., and *H. mollis*, 3 to 5 ft. *H. tuberosus* is the Jerusalem artichoke.

Since the word "sunflower," or something corresponding to it, existed in English literature before the introduction of *Helianthus annuus*, or, at any rate, before its general diffusion in English gardens, it is obvious that some other flower must have been intended. The marigold (*Calendula officinalis*) is considered by Dr Prior to have been the plant intended by Ovid (*Met.* iv. 269–270)—

> ". . . Illa suum, quamvis radice tenetur,
> Vertitur ad solem; mutataque servat amorem "—

and likewise the *solsaece* of the Anglo-Saxon, a word equivalent to *solsequium* (sun-following). But this movement with the sun is more imaginary than real, the better explanation for the application of the name to a flower being afforded by the resemblance to "the radiant beams of the sun," as Gerard expresses it. The rock-rose (*Helianthemum vulgare*) was also termed sunflower in some of the herbals from its flowers opening only in the sunshine. *Actinella grandiflora*, a pretty perennial 6 to 9 in. high, from the Colorado mountains, is known as the Pigmy sunflower.

SUNIUM (*Σούνιον*; mod. Cape Colonna), a cape at the southern extremity of Attica, with a temple of Poseidon upon it, which serves as a landmark for all ships approaching Athens from the east. The rocky promontory on which the temple stands was fortified by a wall with towers, in 413 B.C., as a protection against the Spartans in Decelea; but it was soon after seized by a body of fugitive slaves from the Laurium mines. In the 4th century it was still kept up as a fortress. The temple was shown by an inscription found in 1898 to be dedicated to Poseidon, not, as formerly supposed, to Athena, the remains of whose temple are to be seen about a quarter of a mile away to the north-east; they are of a peculiar plan, consisting of a hall with a colonnade on two sides only. The extant temple on the promontory was probably built in the time of Pericles. It took the place of an earlier one, of similar proportions but built of tufa or "poros" stone. There are still standing nine columns of the south side and two of the north of the peristyle, and one of the *antae* and an inner column of the *pronaos*. They are built of local white marble, which has suffered much from the weather. In form they resemble those of the Parthenon and Theseum, but they have only sixteen flutings. Recent excavations have revealed porticoes, a gateway and other buildings, and also the remains of several colossal early statues, the best preserved of which is now in the museum at Athens. The site of Cape Colonna is extolled by Byron, and is the scene of Falconer's "Shipwreck." (E. Gr.)

SUNN, or India Hemp (*Crotalaria juncea*), a plant which is a native of India and Ceylon. It frequently receives other names, *e.g.* false hemp, brown hemp, Bombay hemp, Jubbulpore hemp, sana, &c. The plant is an annual, requires a light soil, and is easily cultivated. The ground is ploughed two or three times, and from 80 to 100 ℔ of seed are sown broadcast. The seedlings quickly appear above the surface, but it is about four months before the plant begins to flower. Sometimes the seed is sown in October for the winter crop, and sometimes in May or June for the summer crop. When the seeds are sown in May, the bright yellow flowers appear in August, when the plant may be gathered. It is not unusual, however, to defer this operation until the seed is ripe, especially if a fibre of great strength is desired. The stems may be pulled up, as is the case with flax, or they may be cut down. Different opinions exist as to whether the stems should be steeped immediately after they are pulled, or left to dry and then steeped: in the wet districts they are taken direct to the water. Since the root ends are much thicker and coarser than the tops, it is common to place the bundles erect, and to immerse the root ends in about a foot of water. Afterwards the bundles are totally immersed in the ponds, and in two to four days the fibre should be ready for stripping. There is the same danger of over-retting and under-retting as in other fibres, but when the retting is complete, the workmen enter the ponds, take up a handful of stems, and swish them upon the surface of the water until the fibre becomes loose. After the fibre has been peeled off it is hung over poles to dry. When intended for cloth it is combed in order to remove any foreign matter, but if it is intended to be used for rope or similar purposes, the fibres are simply separated and the woody matter combed out with the fingers. The fibre is of a light grey colour, and has an average length of 3 to 4 ft. It is extensively used for rope and cordage and also for paper-making in its native country, but it has made little, if any, progress in this country. According to Warden, the fibre was tried in Dundee in the beginning of the 19th century. About 1820 the price of India hemp bagging, as quoted in the *Dundee Advertiser*, was 1½d. per yard below hemp bagging, and ¾d. a yard below tow warp bagging.

It is stated in Sir G. Watt's *Dictionary of the Economic Products of India* that a cord 8 in. in size of best Petersburg hemp broke with 14 tons, 8 cwt. 1 qr., while a similar rope of sunn only gave way with 15 tons, 7 cwt. 1 qr. Roxburgh's experiments with ropes made from this and other fibres appear on p. 607 of the above work. The ropes were tested in the fresh state, and also after having been immersed in water for 110 days. His results, reproduced in the following table, show the comparison.

Names of the Plants.	Average Weight at which each sort of line broke.					
	When fresh.			After 110 days' maceration.		
	White.	Tanned.	Tarred.	White.	Tanned.	Tarred.
English hemp, a piece of new tiller-rope	105	—	—	Rotten, as was also the English log-line.		
Hemp from the East India Company's farm near Calcutta	74	139	45	All rotten.		
Sunn hemp of the Bengalese	68	69	60	Rotten	51	65
Jute (Bunghi-pāt)	68	69	61	40	49	60

It would appear that, after maceration, neither ordinary hemp nor sunn hemp can compare with jute for strength.

SUNNITES, literally, "those of the path," *sunna*, *i.e.* followers of the Prophet's directions, the name of one of the two main divisions of Islam, the other being the Shīʽites (*q.v.*). The Sunnites, who accept the orthodox tradition (*Sunna*) as well as the Koran as a source of theologico-juristic doctrines, predominate in Arabia, the Turkish Empire, the north of Africa, Turkestan, Afghanistan and the Mahommedan parts of India and the east of Asia; the Shīʽites have their main seat in Persia, where their confession is the state religion, but are also scattered over the whole sphere of Islam, especially in India and the regions bordering on Persia, except among the nomad Tatars, who are all nominally Sunnite. Even in Turkey there are many native Shīʽites, generally men of the upper classes, and often men in high office (see generally Mahommedan Religion).

Orthodox Islam preserves unchanged the form of doctrine established in the 10th century by Abū 'l-Ḥasan al-Ashʽarī (see Ashʽarī). The attacks of rationalism, aided by Greek philosophy, were repelled and vanquished by the weapons of scholastic dialectic borrowed from the enemy; on most points of dispute discussion was forbidden altogether, and faith in what is written in Koran and tradition was enjoined without question as to how these things were true (*bilā kaifa*). Freer allegorical views, however, were admitted on some specially perplexing points, such as the doctrine of the eternity of the Koran, the crude anthropomorphisms of the sacred text, &c.; and, since Moʽtazilite (Muʽtazilite) views had never taken deep root among the masses, while the caliphs required the help of the clergy, and from the time of Motawakkil (A.D. 847) became ever more closely bound to orthodox views, the freethinking tendency was thoroughly put down, and to the present day no rationalizing movement has failed to be crushed in the bud. Philosophy still means no more than scholastic dialectic, and is the humble servant of orthodoxy, no man venturing on devious paths except in secret. In the years 1872–1878 the Afghan Jamāl ud-Dīn, a professor in the Azhar mosque at Cairo, attempted to read Avicenna with his scholars, and to exercise them in things that went beyond theology, bringing, for example, a globe into the mosque to explain the form of the earth. But the other professors rose in arms, forbade him to enter the mosque, and in 1879 procured his exile on the pretext that he entertained democratic and revolutionary ideas. Thus the later movements of thought in Islam never touch on the great questions that exercised Mahommedanism in its first centuries, *e.g.* the being and attributes of God, the freedom of the will, sin, heaven and hell, &c. Religious earnestness, ceasing to touch the higher problems of speculative thought, has expressed itself in later times exclusively in protest against the extravagances of the dervishes, of the worship of saints, and so forth, and has thus given rise to movements analogous to Puritanism.

Ulemā.

That even in early times the masses were never shaken in their attachment to the traditional faith, with all its crude and grotesque conceptions, is due to the zeal of the ulemā (clergy). Mahommedanism has no priesthood standing between God and the congregation, but Koran and Sunna are full of minute rules for the details of private and civil life, the knowledge of which is necessarily in the hands of a class of professed theologians. These are the *'ulemā* (*q.v.*), "knowers," theology being briefly named "the knowledge" (*'ilm*). Their influence is enormous and hardly has a parallel in the history of religions. For it is not supported by temporal agencies like the spiritual authority of the Christian priesthood in the middle ages, but is a pure power of knowledge over the ignorant masses, who do nothing without consulting their spiritual advisers. When the vigorous Spanish sultan Manṣūr b. Abī 'Āmir proposed to confiscate a religious foundation and the assembled ulemā refused to approve the act, and were threatened by his vizier, one of them replied, "All the evil you say of us applies to yourself; you seek unjust gains and support your injustice by threats; you take bribes and practise ungodliness in the world. But we are guides on the path of righteousness, lights in the darkness, and bulwarks of Islam; we decide what is just or unjust and declare the right; through us the precepts of religion are maintained. We know that the sultan will soon think better of the matter; but, if he persists, every act of his government will be null, for every treaty of peace and war, every act of sale and purchase, is valid only through our testimony." With this answer they left the assembly, and the sultan's apology overtook them before they had passed the palace gate.[1] The same consciousness of independent authority and strength still survives among the ulemā. Thus the sheikh ul-Islām 'Abbāsī (who was deposed by the professors of the Azhar in 1882) had in the first period of his presidency a sharp conflict with 'Abbās Pasha, viceroy of Egypt, who asked of him an unjust legal opinion in matters of inheritance. When bribes and threats failed, the sheikh was thrown into chains and treated with great severity, but it was the pasha who finally yielded, and 'Abbāsī was recalled to honours and rich rewards.

The way in which the ulemā are recruited and formed into a hierarchy with a vigorous *esprit de corps* throws an instructive light on the whole subject before us. The brilliant days are past when the universities of Damascus, Bagdād, Nīshāpūr, Cairo, Kairawān, Seville, Cordova, were thronged by thousands of students of theology, when a professor had often hundreds or even, like Bukhārī, thousands of hearers, and when vast estates in the hands of the clergy fed both masters and scholars. Of the great universities but one survives—the Azhar mosque at Cairo—where thousands of students still gather to follow a course of study which gives an accurate picture of the Mahommedan ideal of theological education.

Theological Students.

The students of theology generally begin their course in early youth, but not seldom in riper years. Almost all come from the lowest orders, a few from the middle classes, and none from the highest ranks of society—a fact which in itself excludes all elements of freer and more refined education. These sons of poor peasants, artisans or tradesmen are already disposed to narrow fanaticism, and generally take up study as a means of livelihood rather than from genuine religious interest. The scholar appears before the president's secretary with his poor belongings tied up in a red handkerchief, and after a brief interrogatory is entered on the list of one of the four orthodox rites—Shāfi'ite, Ḥanifite, Mālikite and Ḥanbalite (see MAHOMMEDAN LAW). If he is lucky he gets a sleeping-place within the mosque, a chest to hold his things, and a daily ration of bread. The less fortunate make shift to live outside as best they can, but are all day in the mosque, and are seldom deserted by Moslem charity. Having kissed the hands of the sheikh and teachers of his school, the pupil awaits the beginning of the lectures. For books a few compendiums suffice him. Professors and students gather every morning for the daily prayer; then the professors take their seats at the foot of the pillars of the great court and the students crouch on mats at their feet. The beginner takes first a course in the grammar of classical Arabic, for he has hitherto learned only to read, write and count. The rules of grammar are read out in the memorial verses of the *Ajrūmīya*, and the teacher adds an exposition, generally read from a printed commentary. The student's chief task is to know the rules by heart; this accomplished, he is dismissed at the end of the year with a certificate (*ijāza*), entered in his textbook, which permits him to teach it to others. The second year is devoted to dogmatic (*kalām* and *tawḥīd*), taught in the same mechanical way. The dogmas of Islam are not copious, and the attributes of God are the chief subject taken up. They are demonstrated by scholastic dialectic, and at the end of his second year the student, receiving his certificate, deems himself a pillar of the faith. The study of law (*fiqh*), which rests on Koran and tradition, is more difficult and complex, and begins, but is often not completed, in the third year. The student had learned the Koran by heart at school and has often repeated it since, but only now is the sense of its words explained to him. Of the traditions of the Prophet he has learned something incidentally in other lectures; he is now regularly introduced to their vast artificial system. From these two sources are derived all religious and civil laws, for Islam is a political as well as a religious institution. The five main points of religious law, "the pillars of Islam," have been enumerated in the article MAHOMMEDAN RELIGION; the civil law, on the development of which Roman law had some influence, is treated under heads similar to those of Western jurisprudence. It is here that the differences between the four schools come most into notice: the Ḥanifite praxis is the least rigorous, then the Shāfi'ite; the Ḥanbalites, whose system is the strictest, have practically disappeared in the Mālikites. The Ḥanifite rite is official in the Turkish Empire, and is followed in all government offices whenever a decision still depends on the sacred law, as well as by all Mahommedans of Turkish race. In this as in the previous studies a compendium is learned by heart, and explanations are given from commentaries and noted down by the students word for word. The professors are expressly forbidden to add anything of their own. The recognized books of jurisprudence, some of which run to over twenty folio volumes, are vastly learned, and occasionally show sound sense, but excel mainly in useless hair-splitting and feats of scholastic gymnastics, for which the Arabian race has a natural gift.

Besides the three main disciplines the student takes up according to his tastes other subjects, such as rhetoric (*ma'ānī wabayān*), logic (*manṭiq*), prosody (*'arūḍ*), and the doctrine of the correct pronunciation of the Koran (*qirā'a watajwīd*). After three or four years, fortified with the certificates of his various professors, he seeks a place in a law-court or as a teacher, preacher, cadi, or mufti of a village or minor town, or else one of the innumerable posts of confidence for which the complicated ceremonial of Mahommedanism demands a theologian, and which are generally paid out of pious foundations. A place is not hard to find, for the powerful corporation of the ulemā seeks to put its own members into all posts, and, though the remuneration is at first small, the young *'ālim* gradually accumulates the revenues of several offices. Gifts, too, fall in, and with his native avarice and economy he rises in wealth, position and reputation for piety. The commonalty revere him and kiss his hand; the rich show him at least outward respect; and even the government treats him as a person to whom consideration is due for his influence with the masses.

This sketch of his education is enough to explain the narrow-mindedness of the *'ālim*. He deems all non-theological science to be vain or hurtful, has no notion of progress, and regards true science—*i.e.* theology—as having reached finality, so that a new supercommentary or a new students' manual is the only thing that is perhaps still worth writing. How the mental faculties are blunted by scholasticism and mere memory work must be seen to be believed; such an education is enough to spoil the best head. All originality is crushed out and a blind and ludicrous dependence on written tradition—even in things profane—takes its place. Acuteness degenerates into hair-splitting and clever plays on words after the manner of the rabbins. The Azhar students not seldom enter government offices and even hold important administrative posts, but they never lose the stamp of their education—the narrow, unteachable spirit, incapable of progress, always lost in external details, and never able to grasp principles and get behind forms to the substance of a matter.

Schools.

Yet it is but a small fraction of the ulemā of the Moslem world that enjoy even such an education as the Azhar affords. It draws few students from foreign parts,[2] where the local schools are of the poorest kind, except in India (thanks to a British government) and perhaps in Constantinople.[3] Bokhārā was once a chief seat of learning, but is now so sunk in narrow fanaticism that its eighty *madrasas* (*medresses*) with their 5000 students only turn out a bigoted and foolish clergy (Vámbéry).[4] But for this very reason Bokhārā is famed as a luminary of pure theology and spreads its influence over Turkestan, Siberia, China, Kashmir, Afghanistan, and even over India. Minor schools attached to mosques are found in other places, but teach still less than the great schools already mentioned.

Except in India, where it is controlled by the government,

[1] Von Kremer, *Gesch. d. herrschenden Ideen d. Islams*, p. 464 (Leipzig, 1868).

[2] In 1878 seventeen lecture-rooms of the Azhar had 3707 students, of whom only 64 came from Constantinople and the northern parts of the Ottoman Empire, 8 from North Arabia, 1 from the government of Bagdād, 12 from Kurdistan, and 7 from India with its thirty million Sunnites.

[3] In Kazan also the standard of learning seems to have been raised by Russian and Western scholars.

[4] The *madrasa* is here a college, generally attached to a mosque, with lands whose revenues provide the means of instruction and in part also food and residence for scholars and teachers.

the organization of the priestly and judicial persons trained in the schools is a compromise between what theological principles dictate and what the state demands. Neither Koran nor Sunna distinguishes between temporal and spiritual powers, and no such distinction was known as long as the caliphs acted in all things as successors of the prophets and heads of the community of the faithful. But, as the power of the 'Abbāsids declined (see article CALIPHATE, *ad fin.*) and external authority fell in the provinces into the hands of the governors and in the capital into those of the *amīr al-omarā*, the distinction became more and more palpable, especially when the Būyids, who were disposed to Shī'ite views, proclaimed themselves sultans, *i.e.* possessors of all real authority. The theologians tried to uphold the orthodox theory by declaring the sultanate to be subordinate to the imāmate or sovereignty of the caliphs, and dependent on the latter especially in all religious matters; but their artificial theories have never modified facts. The various dynasties of sultans (Būyids, Ghaznevids, Seljūks, and finally the Mongols) never paid heed to the caliphs, and at length abolished them; but the fall of the theocracy only increased the influence of the clergy, the expounders and practical administrators of that legislation of Koran and Sunna which had become part of the life of the Mahommedan world. The Mamelukes in Egypt tried to make their own government appear more legitimate by nominally recognizing a continuation of the spiritual dignity of the caliphate in a surviving branch of the 'Abbāsid line which they protected, and in 923 A.H. (1517) the Ottoman Selim, who destroyed the Mameluke power, constrained the 'Abbāsid Motawakkil III., who lived in Cairo, to make over to him his nominal caliphate. The Ottoman sultans still bear the title of "successors of the Prophet," and still find it useful in foreign relations, since there is or may be some advantage in the right of the caliph to nominate the chief cadi (*ḳāḍī*) of Egypt and in the fact that the spiritual head of Khiva calls himself only the *naḳīb* (vicegerent) of the sultan.[1] In India too the sultan owes something perhaps to his spiritual title. But among his own subjects he is compelled to defer to the ulemā and has no considerable influence on the composition of that body. He nominates the *Sheikh ul-Islam* or mufti (*q.v.*) of Constantinople (grand mufti), who is his representative in the imāmate and issues judgments in points of faith and law from which there is no appeal; but the nomination must fall on one of the *mollahs*,[2] who form the upper stratum of the hierarchy of ulemā. And, though the various places of religious dignity are conferred by the sultan, no one can hold office who has not been examined and certified by older ulemā, so that the corporation is self-propagating, and palace intrigues, though not without influence, can never break through its iron bonds. The deposition of 'Abd ul-Azīz is an example of the tremendous power that can be wielded by the ulemā at the head of their thousands of pupils,[3] when they choose to stir up the masses; nor would Maḥmūd II. in 1826 have ventured to enter on his struggle with the janissaries unless he had had the hierarchy with him.

Caliphate and Temporal Sovereignty.

The student who has passed his examinations at Constantinople or Cairo may take up the purely religious office of *imām* (president in worship) or *khaṭīb* (preacher) at a mosque. These offices, however, are purely ministerial, are not necessarily limited to students, and give no place in the hierarchy and no particular consideration or social status. On the other hand, he may become a judge or cadi. Every place of any importance has at least one cadi, who is nominated by the government,[4] but has no further dependence on it, and is answerable only to a member of the third class of the ulemā, viz. the mufti or pronouncer of *fatwas*. A fatwa is a decision according to Koran and Sunna, but without reasons, on an abstract case of law which is brought before the mufti by appeal from the cadi's judgment or by reference from the cadi himself. For example, a dispute between master and slave may be found by the cadi to turn on the general question, "Has Zaid, the master of 'Amr,[5] the absolute right to dispose of his slave's earnings?" When this is put to the mufti, the answer will be simply "Yes," and from this decision there is no appeal, so that the mufti is supreme judge in his own district. The grand mufti of Constantinople is, as we have seen, nominated by the sultan, but his hold on the people makes him quite an independent power in the state; in Cairo he is not even nominated by the government, but each school of law chooses its own sheikh, who is also mufti, and the Ḥanifite is head mufti because his school is official in the Turkish Empire.

Judicial Offices.

All this gives the judges great private and political influence. But the former is tainted by venality, which, aggravated by the scantiness of judicial salaries or in some cases by the judge having no salary at all, is almost universal among the administrators of justice. Their political influence, again, which arises from the fusion of private and political law in Koran and Sunna, is highly inconvenient to the state, and often becomes intolerable now that relations with Western states are multiplied. And even in such distant parts as Central Asia the law founded on the conditions of the Prophet's lifetime proves so unsuited to modern life that cases are often referred to civil authorities rather than to canonical jurists. Thus a customary law (*'orf*) has there sprung up side by side with the official sacred law (*sharī'a*), much to the displeasure of the mollahs. In Turkey, and above all in Egypt, it has been found necessary greatly to limit the sphere and influence of the canonical jurists and to introduce institutions nearer to Western legal usage. We do not here speak of the paper constitutions (*khait-i-sherīf*) and the like, created to impose upon Western diplomatists, but of such things as consular and commercial courts, criminal codes, and so forth.

Modern Changes.

The official hierarchy, strong as it is, divides its power with the dervishes. A religion which subdues to itself a race with strongly marked individuality is always influenced in cultus and dogma by the previous views and tendencies of that race, to which it must in some measure accommodate itself. Mahomet himself made a concession to heathen traditions when he recognized the Ka'ba and the black stone; and the worship of saints, which is now spread throughout Islam and supported by obviously forged traditions, is an example of the same thing. So too are the religious orders now found everywhere except in some parts of Arabia. Mystical tendencies in Mahommedanism arose mainly on Persian soil (see ṢŪFĪISM), and Von Kremer has shown that these Eastern tendencies fell in with a disposition to asceticism and flight from the world which had arisen among the Arabs before Islam under Christian influence.[6] Intercourse with India had given Persian mysticism the form of Buddhistic monkery, while the Arabs imitated the Christian anchorites; thus the two movements had an inner kinship and an outer form so nearly identical that they naturally coalesced, and that even the earliest organizations of orders of dervishes, whether in the East or the West, appeared to Mahommedan judgment to be of one type. Thus, though the name of *Ṣūfī* (see ṢŪFĪISM) is first applied to Abū Hāshim, who died in Syria in 150 A.H. (767), we find it transferred without question to the mystical brotherhood which appears in Khorāsān under Abū Sa'īd about 200 A.H. (815/816). Yet these two schools of Ṣūfīs were never quite similar; on Sunnite soil Ṣūfīism could not openly impugn orthodox views, while in Persia it was saturated with Shī'ite heresy and the pantheism of the extreme devotees of 'Alī. Thus there have always been two kinds of Ṣūfīs, and, though the course of history and the wandering habits which various orders borrowed from Buddhism

Ṣūfīs and Dervishes.

[1] Till the Russians gained preponderating influence the khān of Khiva also acknowledged the sultan as his suzerain.

[2] Mollah is the Perso-Turkish pronunciation of the Arabic *maulā*, literally "patron," a term applied to heads of orders and other religious dignitaries of various grades.

[3] Called in Constantinople *softa*, Persian *sōkhta*, burned up, *scil.*, with zeal or love to God.

[4] In Egypt before the time of Sa'īd Pasha (1854–1863) the local judges were appointed by the chief cadi of Cairo, who is sent from Constantinople. Since then they have been nominated by the Egyptian government.

[5] Zaid and 'Amr are the Caius and Sempronius of Arabian law.

[6] *Op. cit.* p. 52 seq.

have tended to bring them closer to one another, we still find that of the thirty-six chief orders three claim an origin from the caliph Abūbekr, whom the Sunnites honour, and the rest from 'Alī, the idol of the Shī'ites.[1] Mystic absorption in the being of God, with an increasing tendency to pantheism and ascetic practices, are the main scope of all Ṣūfīism, which is not necessarily confined to members of orders; indeed the secret practice of contemplation of the love of God and contempt of the world is sometimes viewed as specially meritorious. And so ultimately the word *ṣūfī* has come to denote all who have this religious direction, while those who follow the special rules of an order are known as dervishes (beggars, in Arabic *fuqarā*, sing. *faqīr* —names originally designating only the mendicant orders). In Persia at the present day a Ṣūfī is much the same as a free-thinker.[2]

SUNSHINE. As a meteorological element sunshine requires some conventional definition. There is uninterrupted continuance of gradation from the burning sunshine of a tropical noon to the pale luminosity that throws no shadow, but just identifies the position and shape of the sun through the thin cloud of northern skies.

The Campbell-Stokes Sunshine Recorder.—In the British Isles the sun is allowed to be its own timekeeper and the scorch of a specially prepared card used as the criterion for bright sunshine. The practice arose out of the use of the sunshine recorder which depends upon the scorching effect of a glass sphere in the sun's rays. The original form of the instrument was suggested by J. F. Campbell of Islay in 1857. He used a glass sphere within a hemispherical bowl of wood. The scorching of the wood along successive lines of the bowl as the sun alters its declination from solstice to solstice leaves a rugged monument of the duration and intensity of the sunshine during the half-year, but does not lend itself to numerical measurement. The design of a metal frame to carry movable cards and thus give a decipherable record of each day's sunshine is due to Sir G. G. Stokes. The excursions of the sun to the north and south of the equator are limited by the tropical circles, and the solar record on the hemispherical bowl will be confined within a belt 23° 27′ north and south of the plane through the centre parallel to the equator or perpendicular to the polar axis. Thus a belt 46° 54′ in angular width will be suitable for a sunshine recorder for any part of the world. Whatever place be chosen for the observation the same belt will do if it is set up perpendicular to the earth's polar axis. But there can be no record if the sun is below the horizon; hence any part of the belt projecting above the horizon is not only useless for recording but is liable to shadow a part of the belt where there might be a record. Hence to meet the requirements of a particular locality the belt as set up round the polar axis should be cut in two by a horizontal plane through the centre and the half projecting above the horizontal removed. Reversed it makes a half belt, exactly similar to what is left, and thus each complete belt is cut by a horizontal plane through the centre into two frames suitable for sunshine recorders for the particular locality.

The cutting of the belt may, of course, vary between the direct transverse cut along the polar axis which gives a half-ring belt to be set vertical in order to receive the record for a point on the equator, and the cut perpendicular to the polar axis which divides the belt into two similar rings suitable for recording the sunshine at the poles. Clearly, when the belt is so cut that two complete rings are formed, a continuous record of sunshine throughout the twenty-four hours may be expected, so that for the polar circles the cut will run diagonally between opposite points of the extreme circles of the sun's records. As examples of the cutting of the belt for different latitudes we may put side by side the recorder as used in temperate latitudes (fig. 1) and

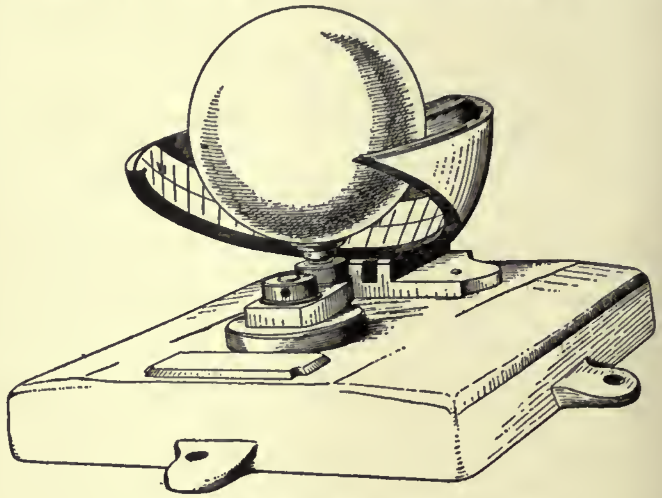

Fig. 1.—Campbell-Stokes Sunshine Recorder.

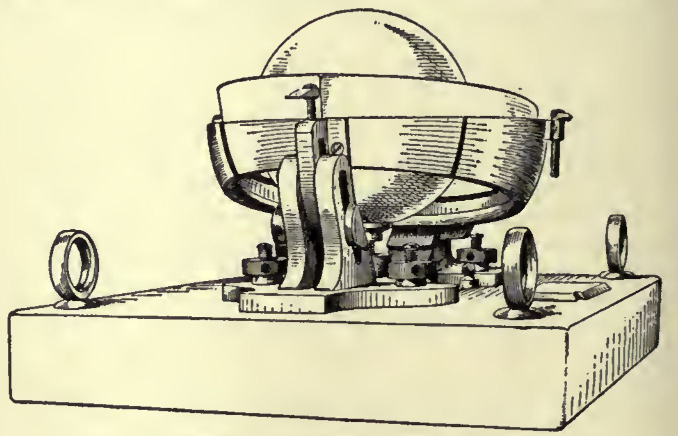
the special form designed in the Meteorological Office, London, for use on the National Antarctic Expedition, 1901–1904 (fig. 2). A belt cut for a particular latitude is serviceable for some 10°



Antarctic Sunshine Recorder, to carry 24-hour record.

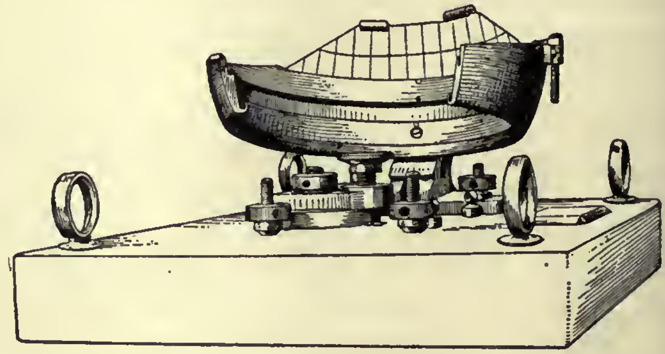


Fig. 2.—Antarctic Sunshine Recorder, to carry 12-hour record.

on either side of that latitude if the cards are not trimmed too closely to the cutting of the belt. The belt must always be adjusted round the parallel to the polar axis. If the cut of the belt is too oblique for the latitude of the place where it is exposed, and the cards are cut strictly to the belt, the northern side of the cut will be below the horizon and the southern side above it,

[1] These claims to early origin are mere fables, like the claim of the Oweisī order to spring from Oweis, one of the oldest traditionalists, and so forth.

[2] For the dervish orders see Dervish.

some sunshine may be lost near sunrise or sunset in the winter because there is no card to receive it. The part projecting above the horizon in summer will partly shadow the globe, and faint sunshine may be lost, for at most only half the globe can be solarized at sunset. But the loss due to this cause is unimportant. Stokes designed the complete belt to use successively three cards

(From the *Observer's Handbook*, by permission of the Controller of H.M. Stationery Office.)

FIG. 3.

of different shape for different times of the year. The equinoctial card forms a portion of a cylinder round the polar axis for spring and autumn, the summer card and the winter card each forms a part of a cone making a vertical angle of 16° with the polar axis as indicated in fig. 3.

Adjustments.—The adjustments of the instrument are to set the belt so that its axis is parallel to the polar axis and symmetrically adjusted with reference to the meridian of the place, and to set the sphere so that its centre coincides precisely with the centre of the belt. No one of the three adjustments is easy to make or to test because neither the centre of the sphere nor the centre (nor indeed the axis) of the belt can be easily identified. For an instrument for testing these adjustments see *Quart. Journ. Roy. Met. Soc.* xxxii. 249.

Instruments differ according to the means provided for mounting or adjusting the positions of the belt or sphere, and in that known as the Whipple Casella instrument the fixed belt is replaced by a movable card holder. The chief advantage of Stokes's specification is the simplicity of the use of the instrument when once it has been properly adjusted and fixed.

It is essential that the glass sphere should be of the proper size and refractive index to give an image of the sun on the prepared card or within the 20th of an inch of it nearer the centre. It is also essential that the cards used should not only be of suitable material but also of the right dimensions for the bowl. The colour and material of the cards were selected by Stokes in consultation with Warren De la Rue, who was at that time his colleague on the Meteorological Council, and the cards used by the meteorological office are still supplied by Messrs De la Rue & Co. Accuracy in the comparative measurements of sunshine by this method depends upon the proper adjustment of the dimensions of the different constituent parts of the recorder and accordingly the following specification of standard dimensions has been adopted by the meteorological office.

The Time Scale.—On the time scale of the equinoctial card twelve hours are represented by 9·00 in.

The Bowl.—The diameter of the bowl, measured between the centres of the 6 o'clock marks on a metal equinoctial card of thickness 0·02 in. when in its place, is to be 5·73 in. (± 0·01 in.). The distance between the exposure edges of the upper winter flange and the lower summer flange must not be less than 2·45 in., nor exceed 2·50 in. The distances from the middle line on the equinoctial card to the middle lines on the summer and winter cards are to be 0·70 in. (± 0·02 in.). The inclination of the summer card, in place, to the winter card, in place, is to be 32° ± ½°, symmetrically arranged with regard to the equinoctial card. The section of the supporting surface by a plane through the polar axis is to be as in fig. 3.

The Sphere.—The material for the sphere must be "crown" glass, colourless, or of a very pale yellow tint. The diameter 4 in. The weight between 2·92 and 3·02 ℔. The focal length from the centre of the sphere to the geometrical focus for parallel rays should be between 2·96 in. and 2·99 in.

Measurement of the Sunshine Record.—It was mentioned that the Campbell-Stokes recorder involves a conventional definition of sunshine. The recorded day of sunshine is less than the actual time during which the sun is above the horizon by about twenty minutes at sunrise and sunset on account of the want of burning power of a very low sun. Some further convention is necessary in order to obtain a tabulation of the records which will serve as the basis of a comparison of results for climatological purposes. The spot which is scorched on the card by the sun is not quite limited to the image of the sun, and a few seconds of really strong sunshine will produce a circular burn which is hardly distinguishable in size from that of a minute's record. (See fig. 4.) Consequently with intermittent sunshine exaggeration of the actual duration of burning is very probable. Strictly speaking measurements ought to be between the diameters of the circular ends of the burns, but the practice of measuring all the trace that can be distinctly recognized as scorched has become almost universal in Great Britain, and appears to give a working basis of comparisons.

FIG. 4.—Records obtained by exposing a Campbell-Stokes Sunshine Recorder for measured intervals varying from one second to thirty minutes. The duration of the exposure of the separate burns increases from right to left of the diagram.

Other Types of Sunshine Recorder.—There are, however, various other conventions as to sunshine which are used as the basis of recorders of quite different types. The Jordan recorder uses ferrocyanide paper and the sun keeps the time of its own record by the traverse of a spot of light over the sensitive paper, arranged as a cylinder about a line parallel to the polar axis. The effect thereby recorded is a photochemical one, and the composite character of the sun's radiation, modified by the elective absorption of the atmosphere makes the relation of the record to that of the sun's scorching power dependent upon atmospheric conditions and therefore on different occasions, so that the two records give different aspects of the solar influence. Other recorders use the thermal or photographic effect

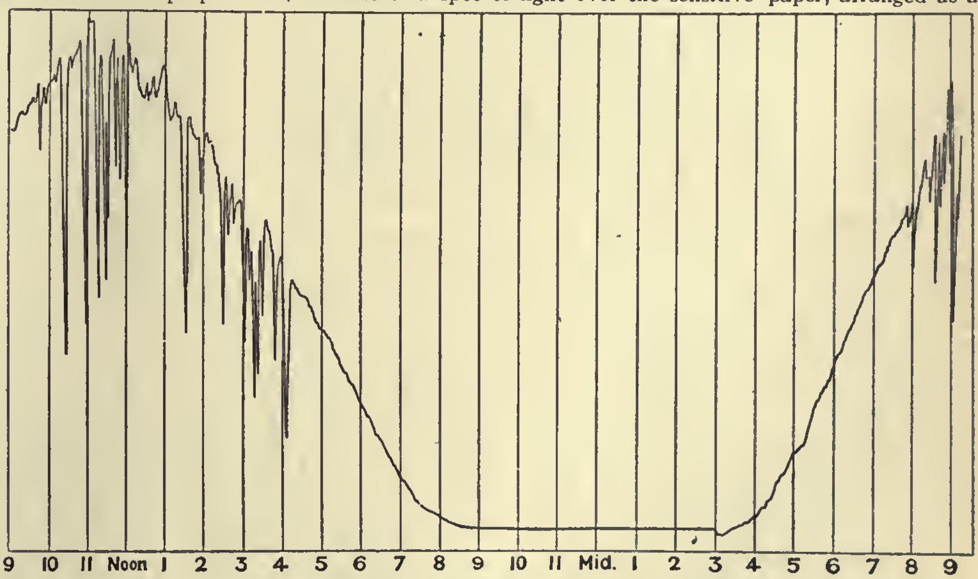

FIG. 5.—Sunshine Record (June 19 and 20, 1908).

of the sun's rays and record duration by a clock instead of allowing the sun to keep its own time. In the Marvin sunshine recorders of

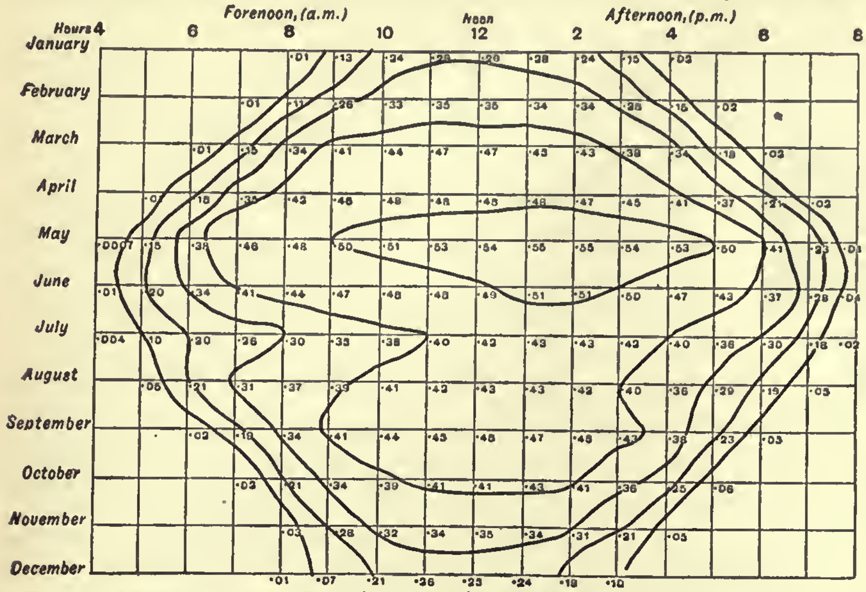

FIG. 6.—Monthly Average Duration of bright Sunshine for each hour of the day at Valencia (Ireland).

the United States weather bureau an electrical contact is made by the thermal effect of the sun and the duration of the contact is recorded. An instrument which gives a corresponding result is described by W. H. Dines (*Quart. Journ. Roy. Met. Soc.* xxvi. 243). These define sunshine by the effect necessary to produce or maintain a certain thermal effect, but the definition once accepted there is no uncertainty as to the record. The Callendar sunshine recorder[1] gives a record of the difference of temperature of two wires, one solarized and the other not, and it is therefore a continuous record of the thermal effect of solar and terrestrial radiation. It is vastly more detailed than that of other instruments (see fig. 5), but the interpretation of the record in terms suitable for meteorological or climatological purposes is a special study, which has not yet been attempted. In a somewhat similar way information about the duration and intensity of sunshine with an abundance of detail can be obtained from the record upon photographic paper passing under an aperture in a drum which revolves with the sun, as in the Lander recorder, but the study of such details has not been begun.

Sunshine Records for the British Isles.—The interest in the use of sunshine recorders is more widely extended in the British Isles than elsewhere, and it is, so far as the public are concerned, the most important meteorological element, but it is singular that up to the present a knowledge of the total amount of sunshine recorded during the day, the week, the month or the year is all that is apparently required. Except for the observatories in connexion with the meteorological office and a few others the distribution of sunshine during the day is not taken out, so that we are still some distance from attacking the problems presented by the finer details of solar records. Fig. 6 shows the average duration of bright sunshine for each hour of the day for each month at Valencia. The expectation of sunshine is greatest at 1 p.m. and 2 p.m. in May, while there is a well-marked secondary maximum in September.

Exposure.—We now consider what the daily sunshine record for a particular station means. An ideal exposure has an uninterrupted view of those parts of the horizon in which the sun rises or sets; and elsewhere the view of the sun must not be obstructed by the ground, buildings, trees or any other obstacle; but ideal exposures are not always to be obtained. In mountainous districts particularly it may be impossible to find a site in which the sun is not obstructed for an appreciable part of the day. In these circumstances it becomes a question whether the amount of sunshine recorded should be referred to the maximum possible for an uninterrupted horizon or the maximum possible for the particular exposure. The answer to the question really depends upon the purpose for which the information is wanted. As a climatological factor of the locality the shadow cast by the surrounding hills is of importance, it is part of the difference between the fertility of the southern and northern slopes of hill country. This importance is, of course, in many respects exclusively local, and indeed the possible duration of sunshine at any station is a local characteristic which it is desirable to know. Consequently as evidence of the peculiarity of the site the recorded sunshine might be referred to the total possible with a free horizon. On the other hand, taking the record of sunshine as an indication of the clearness of the sky for the purposes of general meteorology, the screening of the sun by hills must be regarded simply as limiting the time during which observation is possible and the duration of the sunshine recorded should be referred to the possible duration at the particular site. It would, therefore, be desirable in publishing records of the duration of sunshine recorded to note also the possible amount for the instrument as exposed (see *Hourly Means at Five Observatories under the Meteorological Council*, 1891, No. 113, p. 10). The table shows the number of hours the sun is above the horizon during each month in the latitude of the British Isles.

Possible Duration of Bright Sunshine in the Latitude of the British Isles.

Latitude.	Jan.	Feb.	Leap Year.	March	April	May	June	July	Aug.	Sept.	Oct.	Nov.	Dec.
50°	262	278	288	365	410	473	482	485	442	373	327	266	246

By way of exhibiting the results obtained from sunshine records we reproduce (fig. 7) the sunshine map of the British Isles taken from the annual summary of the Monthly "Weather Report," 1908 (*British Meteorological Year-Book*, pt. ii.). Corresponding maps embodying data from over 130 stations are prepared each month; fig. 8 shows the variation in the distribution of sunshine that may take place in different months. Further, fig. 9 represents the average weekly distribution of sunshine in different sections of the British Isles according to the average of twenty-five years.

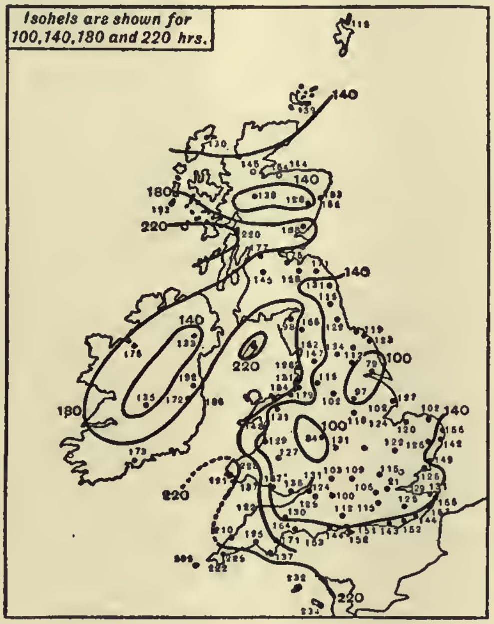
FIG. 7.—Sunshine in the British Isles in 1908.

Sunshine in the Antarctic Regions.—It is clear that so far as concerns the zone from 50° to 60° N. in this particular region, the annual amount of sunshine diminishes as one goes northward. It would, however, not be safe to conclude that this diminution in the aggregate duration of sunshine during the year goes on without interruption as one proceeds northward. At least the corresponding statement would not be true of the southern hemisphere. No doubt

[1] *Brit. Assoc. Report* (1900), p. 44.

the frequency of cloud and the consequent loss of duration of sunshine would increase for corresponding latitudes from the tropical anticyclone southward, but beyond the region of minimum pressure at the winter quarters of the "Discovery" in latitude 77° 51′ S., longitude 166° 45′ E., the amount of bright sunshine recorded during the two years 1902 and 1903 was remarkably large. The total for 1903 equalled that for Scilly, and in December of that year an average of 16 hours per day was registered.

May 1909.



June 1909.

FIG. 8.—Sunshine in the British Isles in May and June 1909.

Sunshine Results for Other Parts of the World.—Maps showing the average annual distribution of sunshine over Europe and North America are given in Bartholomew's *Physical Atlas*, vol. iii. *Atlas of Meteorology*. Over Europe the largest totals, over 2750 hours per annum, are shown over central Spain. In North America, values exceed 3250 hours per annum in the New Mexico region. For other parts of the world the information available is not sufficiently extensive for the construction of charts.

Effect upon Sunshine Records of the Smoke of Great Cities.—Much discussion has taken place from time to time as to whether the climate of a locality can be altered by artificial means. Questions have been raised as to the effect of forests upon rainfall, as to the indirect effect of irrigation or the converse process, the obliteration of natural irrigation by blown sand, and as to the possibility of producing, arresting or modifying rainfall by the discharge of explosives.

The one question of the kind to which the sunshine recorder gives an absolutely incontrovertible answer is as to the effect of the smoke of great cities in diminishing the sunshine in the immediate

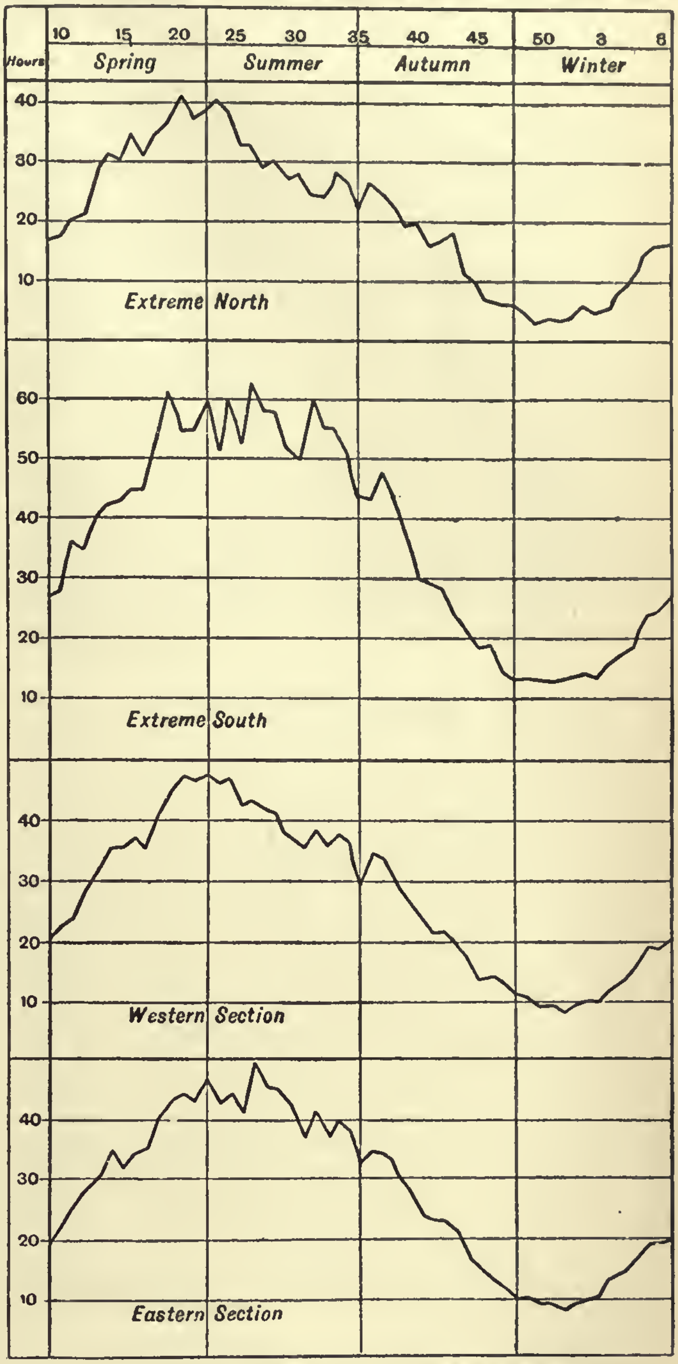


FIG. 9.—Average Duration of bright Sunshine in the British Isles for each week.

neighbourhood. This may be illustrated by the figures for sunshine during the winter months off Bunhill Row, E.C., in the middle of London, Westminster, Kew and Cambridge.

Monthly Average Duration of Bright Sunshine derived from Observations extending over Twenty Years.

Station.	November.	December.	January.	February.
Bunhill Row . .	22·8	7·5	14·1	30·6
Westminster . .	27·7	13·1	18·4	32·8
Kew	50·8	38·1	40·3	54·6
Cambridge . . .	61·0	40·6	48·9	73·8

This is not a question which comes out merely by taking averages. The answer can be seen directly by comparing the daily cards (see fig. 10, Sunshine Cards for Cambridge, Westminster and Bunhill Row for December 1904). Thus it appears that the direct effect of the local contamination of the London atmosphere results in the diminution of the recorded sunshine for the whole year by 37%, and it is clear that the contamination extends in some degree as far as Kew, where the loss amounts to about 10%. There is evidence of various kinds to show that the effect of the smoke cloud of cities

Cambridge. Westminster. Bunhill Row.

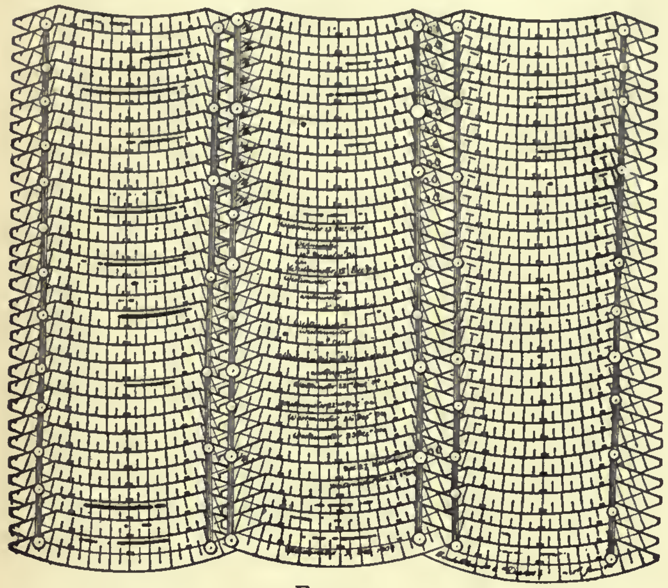

FIG. 10.

can be traced sometimes for great distances, and in special conditions of weather with easterly winds the effect is sometimes remarkably persistent. (W. N. S.)

SUNSTONE, a felspar exhibiting in certain directions a brilliant spangled appearance, which has led to its use as an ornamental stone. The effect appears to be due to reflections from enclosures of red haematite, in the form of minute scales, which are hexagonal, rhombic or irregular in shape, and are disposed parallel to the principal cleavage-plane. These enclosures give the stone an appearance something like that of aventurine (*q.v.*), whence sunstone is known also as "aventurine-felspar." It is not common, the best-known locality being Tvedestrand, near Arendal, in south Norway, where masses of the sunstone occur embedded in a vein of quartz running through gneiss. It is found also near Lake Baikal, in Siberia, and at several localities in the United States, notably at Middletown, Delaware county, Pennsylvania, and at Statesville in North Carolina. The felspar which usually displays the aventurine appearance is oligoclase (*q.v.*), but the effect is sometimes seen also in orthoclase (*q.v.*): hence two kinds of sunstone are distinguished as "oligoclase sunstone" and "orthoclase sunstone." The latter has been found near Crownpoint and at several other localities in the state of New York, as also at Glen Riddle in Delaware county, Pennsylvania, and at Amelia Court House, Amelia county, Virginia.

SUNSTROKE (*Heatstroke*; *Insolation*; *Thermic Fever*; *Siriasis*), a term applied to the effects produced upon the central nervous system, and through it upon other organs of the body, by exposure to the sun or to overheated air. Although most frequently observed in tropical regions, this disease occurs also in temperate climates during hot weather. A moist condition of the atmosphere, which interferes with cooling of the overheated body, greatly increases the liability to suffer from this ailment.

Sunstroke has been chiefly observed and investigated as occurring among soldiers in India, where formerly, both in active service and in the routine of ordinary duty, cases of this disease constituted a considerable item of sickness and mortality. The increased attention now paid by military authorities to the personal health and comfort of the soldier, particularly as regards barrack accommodation and dress, together with the care taken in adjusting the time and mode of movement of troops, has done much to lessen the mortality from this cause. It would appear that, while any one exposed to the influence of strong solar heat may suffer from the symptoms of sunstroke, there are certain conditions which greatly predispose to it in the case of individuals. Causes calculated to depress the health, such as previous disease, particularly affections of the nervous system—anxiety, worry or overwork, irregularities in food, and in a marked degree intemperance—have a powerful predisposing influence, while personal uncleanliness, which prevents among other things the healthy action of the skin, the wearing of tight garments, which impede the functions alike of heart and lungs; and living in overcrowded and insanitary dwellings have an equally hurtful tendency.

While attacks of sunstroke are frequently precipitated by exposure, especially during fatigue, to the direct rays of the sun, in a large number of instances they come on under other circumstances. Cases are of not infrequent occurrence among soldiers in hot climates when there is overcrowding or bad ventilation in their barracks, and sometimes several will be attacked in the course of a single night. The same remark applies to similar conditions existing on shipboard. Further, persons whose occupation exposes them to excessive heat, such as stokers, laundry workers, &c., are apt to suffer, particularly in hot seasons. In the tropics Europeans, especially those who have recently arrived, are more readily affected than natives. But natives are not exempt.

The symptoms of heatstroke, which obviously depend upon the disorganization of the normal heat-regulating mechanism, as well as of the functions of circulation and respiration, vary in their intensity and likewise to some extent in their form. Three chief types of the disease are usually described.

1. *Heat Syncope.*—In this form the symptoms are those of exhaustion, with a tendency towards fainting or its actual occurrence. A fully developed attack of this description is usually preceded by sickness, giddiness, some amount of mental excitement followed by drowsiness, and then the passage into the syncopal condition, in which there are pallor and coldness of the skin, a weak, quick and intermittent pulse, and gasping or sighing respiration. The pupils are often contracted. Death may quickly occur; but if timely treatment is available recovery may take place.

2. *Heat Apoplexy or Asphyxia.*—In this variety the attack, whether preceded or not by the premonitory symptoms already mentioned, is usually sudden, and occurs in the form of an apoplectic seizure, with great vascular engorgement, as seen in the flushed face, congested eyes, quick full pulse and stertorous breathing. There is usually insensibility, and convulsions are not infrequent. Death is often very sudden. This form, however, is also amenable to treatment.

3. *Thermic Fever.*—This variety is characterized chiefly by the excessive development of fever (hyperpyrexia), the temperature of the body rising at such times to 108° to 110° F. or more. Accompanying this are the other symptoms of high febrile disturbance, such as great thirst, quick full pulse, pains throughout the body, headache, nausea and vomiting, together with respiratory embarrassment. After the attack has lasted for a variable period, often one or two days, death may ensue from collapse or from the case assuming the apoplectic form already described. But here, too, treatment may be successful if it is promptly applied.

Besides these, other varieties depending on the prominence of certain symptoms are occasionally met with. The chief changes in the body after death from heatstroke are those of anaemia of the brain and congestion of the lungs, together with softness of the heart and of the muscular tissues generally. The blood is dark and fluid and the blood corpuscles are somewhat altered in shape. Attacks of sunstroke are apt to leave traces of their effects upon the constitution, especially upon the nervous system. A liability to severe headache, which in many cases would seem to depend upon a condition of chronic meningitis, epileptic fits, mental irritability and alterations in the disposition are among the more important. It is often observed that heat in any form is ever afterwards ill borne, while there also appears to be an abnormal susceptibility to the action of stimulants. The mortality from sunstroke is estimated at from 40 to 50%.

Treatment.—Means should be adopted to prevent attacks in the case of those who must necessarily be exposed to the sun. These consist in the wearing of loose clothing, with the exception of the head-dress, which ought to be worn close to the head, in due attention to the function of the skin, and in the avoidance of alcoholic and other excesses. Cold water may be drunk in small quantities at frequent intervals. Sleeping in the open air in very hot seasons is recommended. The treatment of a patient suffering from an attack necessarily depends upon the form it has assumed. In all cases he should if possible be at once removed into a shaded or cool place. Where the symptoms are mostly those of shock and there is a tendency to death from heart failure, rest in the recumbent position, the use of diffusible stimulants, such as ammonia or ether, &c., together with friction or warmth applied to the extremities, are the means to be adopted. Where, on the other hand, the symptoms are those of apoplexy or of hyperpyrexia, by far the most successful results are obtained by the use of cold (the cold affusion, rubbing the surface with ice, enemata of ice-cold water). The effect is a marked lowering of the temperature, while at the same time a stimulus is given to the respiratory function. Mustard or turpentine applied to the nape of the neck or chest is a useful adjuvant. Should the temperature be lowered in this way but unconsciousness still persist, removal of the hair and blistering the scalp are recommended. The subsequent treatment will depend upon the nature of the resulting symptoms, but change to a cool climate is often followed by marked benefit.

SUPERANNUATION (formed on the basis of "annual," "annuity," from the Late Lat. *superannatus*, one that has lived beyond the year, *super*, above, and *annus*, year, Fr. *suranner*, to grow very old), properly a disqualification or relief from office or service on account of old age, infirmity, or of passing the limit of age fixed for service, hence the pension or allowance granted in respect of service at the expiry of the term or the retirement (see PENSION). Educationally the term is specifically used of the removal of a backward pupil, who would otherwise remain in a class or form below that which his age demands.

SUPERCARGO, a term in maritime law (adapted from the Span. *sobrecargo*, one over or in charge of a cargo) for a person employed on board a vessel by the owners of the cargo to manage their trade, sell the merchandise at the ports to which the vessel is sailing, and buy and receive goods for shipment homewards. He has control of the cargo unless expressly or impliedly limited by his contract or agreement. He differs from a factor, who has a fixed place of residence at a port or trading place, by sailing from port to port with the vessel to which he is attached.

SUPEREROGATION (Late Lat. *supererogatio*, payment beyond what is due or asked, from *super*, beyond, *erogare*, to pay out, expend, *ex*, out, *rogare*, to ask), the performance of more than is asked for, the action of doing more than duty requires. In the theology of the Roman Church, "works of supererogation" are those which are performed beyond what is required by God, thus forming a reserve store of works of merit which can be drawn upon for the dispensation of those whose works fall short of the standard required.

SUPERINTENDENT, a term which, apart from its general use for an official in charge, has a distinct religious connotation, being applied, *e.g.* to the head of a Sunday school and to the chief minister in a Methodist circuit. In its most important historical sense it refers to certain ecclesiastical officers of reformed churches of the Lutheran model.

At the Reformation the question of the ordering and constitution of the churches was urgent. The greatest confusion prevailed: the priests were often dissolute, the people were ignorant, and meanwhile nobles were seizing the Church lands. Luther and Melanchthon would have preferred to retain the old episcopal control, and to have charged the bishops with the duty of making the necessary alterations in the ecclesiastical constitution. For, while they taught that in spiritual powers all ministers were equal, they recognized the propriety of allowing administrative distinctions. But the bishops were unwilling to come to any terms with the Reformers, and it became necessary to appoint officers of some new kind. The name of superintendent was then given to a class of men who discharged many of the functions of the older bishops, while bearing a character which in several respects was new. Only in Denmark was the name of bishops reserved for the new officers after the Lutheran model had been adopted and the older bishops had been deposed and imprisoned. It is still used there, though no claim is made that it is the sign of formal apostolical succession. In Scotland the *First Book of Discipline* provided not only for ministers, teachers, elders and deacons, but also for superintendents and readers. The superintendents (who were appointed because of the scarcity of Protestant pastors) took charge of districts corresponding in some degree with the episcopal dioceses, and made annual reports to the general assembly of the ecclesiastical and religious state of their provinces, in the churches of which they also preached.

The distinctive character borne by the new officers was determined by the cardinal principles which Luther had laid down in his work regarding the religious functions of the state. He conceived of the secular government as an ordinance of God, and as being set to direct and control the external fortunes of the Church. He hoped that righteous magistrates would at all times form a sound court of appeal in times of ecclesiastical disorder, and that they would guard the interests of truth and justice more securely than had been done under papal jurisdiction. The superintendents who now had to undertake large administrative responsibilities in the Church were therefore to be appointed by the civil power and to be answerable to it. They were to stand as intermediaries between the prince or magistrates on the one hand, and the ministers in their districts on the other.

In his earlier writings Luther had laid his main emphasis on the spiritual priesthood of all believers. Every sincere Christian was declared free, not only to preach, but also to administer the sacraments and to rebuke evil livers. The differences in office and function between the members implied no difference in rank, for the members of Christ's Church were all members of His body, and Luther believed that they would all be ruled into true order and charity by the Head. But he was shaken by the Peasants' War, and his faith in the virtues of the average man never recovered itself. The result was seen in his later writings, where he expresses his conviction that men need to be directed and restrained from without, and he looks to the state to undertake this duty. In the last resort the civil magistrates must take control of the Church. His vindication for thus subordinating the ecclesiastical to the civil lay in his assumption that the rulers of a Christian land would themselves be Christian, and that it was the Christian duty of the Church to render obedience to those who had been ordained of God to bear rule. He, and the rest of the Reformers, were as firm believers in a visible Catholic Church as were any of those of whom he speaks as "the adherents of the old religion," and Luther, always conservative in feeling, clung to an alliance with the state and denied that the repudiation by the Reformers of papal authority had severed them from the visible Church.

The character of the office and duties of the superintendent were not everywhere the same. Luther shrank from imposing any stereotyped forms and asked that the special circumstances of each separate district should be consulted. He hoped that as few changes as possible would be made, and trusted that the reformed doctrines would spread peacefully throughout the country. After the Diet of Speyer (1526) the civil authorities were invited to reorganize the Church in their respective dominions as they thought best. This was not felt to present any great difficulties in the free towns, for institutions of self-rule had there grown strong and schemes of ecclesiastical readjustment were speedily drawn up. Richter and Sehling[1] have published a number of these ordinances, and they show that as a rule one of the city clergy was appointed superintendent by the city fathers and set in a position of administrative authority over all the churches within their jurisdiction. They were answerable to those fathers for their good order. Greater difficulties presented themselves in the territories of the German princes, and in the case of Saxony Luther proposed to the elector that his first step should be to send out a commission of visitation which should report on the moral and spiritual condition of his principality, district by district. His proposal was carried out, and Luther himself became one of the visitors (1527–1528). He found the people in a state of such religious indifference and ignorance, and the clergy living often in such grossness, that his faith in their fitness to govern themselves ecclesiastically sank even lower than before, and he resisted all schemes for self-government such as had been proposed by Francis Lambert. The church organization which he devised for Saxony provided

[1] In their works on *Die evangelischen Kirchenordnung des 16ten Jahrhunderts* (Weimar, 1846; and Leipzig, 1902–1904).

no place for democratic or representative elements: the grasp of the state must at all times be felt. The superintendent must speak at all times as a minister of the state, and the state must be represented in the synod to which he makes his first report, for upon the synod there must sit not only the pastors but also a delegate from every parish. If any appeal should be made from the decisions of the synod it must be heard in the court of the electoral prince, for he, as supreme civil ruler, possessed the *jus episcopale*, the right of oversight of the churches. Luther proposed that he should exercise this right by appointing a consistorial court composed in part of theologians and in part of canon lawyers, and it was thus that in 1542 the Wittenberg ecclesiastical consistory was formed. Other principalities adopted the model, so that the institution became common throughout the Lutheran churches.

In this scheme the superintendent (or superattendant) was charged with such part of the duty of the older bishops as had been purely administrative. He must concern himself with the discharge of their duties by the pastors of the churches, as well as with their character and demeanour. He must supervise their conduct of public worship, as well as give them licence to preach. He must take cognizance of their ministry to the indigent in their parishes, and of their management of the schools. He must further direct the studies of candidates for the pastoral office. He was answerable to the civil authorities to report all evil-living and false teaching, and those authorities had final power in the matters referred to them. If those matters, however, presented technical difficulties, they could be referred to the consistorial courts.

The earliest occasion of the appointment of such a superintendent would seem to be found in the decisions of Prince John of Saxony about 1527. He assigns the duties of the office, and summons the newly appointed officer to give diligent heed to the conduct and teaching of the pastors under him, faithfully to warn them of all errors, and, in case they prove obstinate, to report them to the electoral court. He must further give close attention to the due observance of the marriage laws, for in this matter the previously appointed visitors to the principality had reported grave laxity. The title of this office was not new, but was taken over from the later Scholastics, who had employed it as a suitable translation of the word ἐπίσκοποι, but Prince John made it clear that his superintendents were not to be bishops in the old sense of the term. For every pastor was declared in the reformed doctrine to be truly a bishop and to have the spiritual functions and authority of a bishop; but the older bishops had also claimed a large number of administrative powers, and these for the future must be retained in the hands of the secular power, which would express itself in the first instance through the state-appointed superintendent. In the few cases in which the old bishoprics were retained in Lutheran communities their tenants held office directly from the state.

Some of the smaller principalities appointed but a single superintendent for their territory, who, instead of being answerable to a consistory, sat as spiritual member on the territorial council, whilst in towns the superintendent was summoned to the town council whenever Church matters arose for discussion. In larger states there were various classes of superintendents with their respective duties severally assigned.

In modern times the functions of the superintendent have been somewhat confused in consequence of the introduction into Lutheran Church theory of inconsistent elements of Presbyterian and synodal type.

See T. M. Lindsay, *History of the Reformation* (1906), i. 400–416; and the articles "Kirchenordnung" and "Superintendent" in Herzog-Hauck's *Realencyklopädie für protestantische Theologie und Kirche.* (E. Ar.*)

SUPERIOR, the most north-westerly of the Great Lakes of North America, and the largest body of fresh water in the world, lying between 46° 30′ and 48° N., and 84° 30′ and 92° W. It is bounded E. and N. by the province of Ontario, W. by the state of Minnesota, and S. by Wisconsin and Michigan. It has deep, extremely cold, clear water, and high and rocky shores along a large portion of its coast. Its general form is that of a wide crescent convex towards the north, but its shores are more irregular in outline than those of the other lakes. Following the curves of its axis from west to east the lake is about 383 m. long, and its greatest breadth is 160 m. Its maximum recorded depth is 1008 ft., and its height above mean sea level is 602 ft., or about 21 ft. above that of lakes Michigan and Huron, to which it is joined at its eastern extremity through the river St Mary. The lake receives the waters of 200 rivers, and drains a territory of 48,600 sq. m., the total area of its basin being 80,400 sq. m. The largest river which empties into it is the St Louis, at its western end. The principal rivers on the north shore are the Pigeon, which forms the international boundary line, the Kaministikwia, the Nipigon, which drains the lake of the same name and together with the lake is about 200 m. long, the Pic, the White and the Michipicoten. No large rivers empty into Lake Superior from the south. There are not many islands in the lake, the largest being Isle Royal, 44 m. long; Michipicoten Island in the eastern part; St Ignace, in the northern part, off the mouth of the Nipigon River; Grand Island between Pictured Rocks and Marquette; Manitou Island, east of Keweenaw Point, and the Apostle Group, to the north of Chequamegon Bay.

The boundary between the United States and Canada runs up the middle of the outlet of the lake and follows a median line approximately to about mid-lake; thence it sweeps northwestward, so as to include Isle Royal within the territory of the United States, and continues near the north shore, to the mouth of Pigeon River, which it follows westward, leaving the whole west end of the lake in United States territory.

Lake Superior lies in a deep rift in rocks principally of Archean and Cambrian age, of the Laurentian, Huronian and Keweenaw formations, rich in minerals that have been extensively worked. The lake is, as it were, surrounded by iron, which is the probable cause of very strong magnetic fields of influence. Native silver as well as silver ores exist around Thunder Bay, native copper was formerly worked on Isle Royal, and rich copper mines are worked on the south shore, while nickel abounds in the country north of the lake. The Archean rocks produce a picturesque coast-line, the north shore particularly being indented by deep bays surrounded by high cliffs, mostly burnt off and somewhat desolate; the islands also rise abruptly to considerable heights, the north shore furnishing the boldest scenery of the Great Lakes. On the south coast, opposite the broadest part of the lake, are precipitous walls of red sandstone, extending about 14 m., famous as the Pictured Rocks, so called from the effect of wave action on them. There are no appreciable tides and little current. A general set of the water towards the outlet exists, especially on the southern shore. From the Apostle Islands to the eastward of Keweenaw point this current has great width, and towards the eastern end of the lake spreads out in the shape of a fan, a branch passing to the northward and westward reaching the north coast. Autumn storms raise dangerous seas. The level varies with the season, and also from year to year, the maximum variation, covering a cycle of years, being about 5 ft. The discharge of the lake is computed to be 75,200 cubic ft. per second at mean stage of water.

The season of navigation, controlled by the opening and closing of the Sault Ste Marie canals, averages about eight months—from the middle of April to the middle of December. The season has been extended for a few days, in both spring and autumn, by the use of ice-breaking tugs at Fort William and Port Arthur, this service being organized by the government particularly to facilitate the movement of grain from the Canadian North-west. The lake never freezes over, though the temperature of the water does not, even in summer, rise far above freezing point. The bays freeze over and there is border ice, often gathered by wind into large fields in the bays and extremities of the lake.

Lake Superior is fairly well provided with natural harbours, and works of improvement have created additional harbours of refuge at various points. Marquette, Mich., Presque Ile Point, Mich., Agate Bay, Minn., Grand Marais, Minn., and Ashland, Wis., are on bays which have protective breakwaters across their mouths. Duluth, Superior, Port Wing, Wis., Ontonagon, Mich., and Grand Marais, Mich., are harbours with entrances formed by parallel jetties extending across obstructing bars. On the Canadian side Fort William, in the mouth of the Kaministikwia, and Port Arthur, four miles distant, an artificial harbour, are the only important shipping points, being the lake terminals of three great transcontinental railway systems, though the whole north shore is liberally supplied with natural harbours. The traffic on Lake Superior grows constantly in volume, the increase in tonnage of each year over that of the preceding year having, for 50 years past, averaged 20%. The freight carried into and out of the lake, as gauged by the statistics gathered at the Sault Canal offices, aggregated in 1907 over 58,000,000 (short) tons. The principal freight shipped eastward consists of flour, wheat and other grains, through Duluth–Superior from the United States, and through Fort William–Port Arthur from the Canadian prairies; copper ore from the mines on the south shore; iron ore in immense quantities from both shores, the principal ore shipping ports being Ashland, Two Harbors, Marquette, Superior and Michipicoten, and lumber produced on the tributary rivers. West-bound freight consists largely of coal for general distribution and for terminal railway points.

The fishing industry of Lake Superior is important, salmon-trout (*Salvelinus namaycush*, Walb), ranging from 10 to 50 lb in weight, being gathered from the individual fishermen by steam tenders and shipped by rail to city markets. The river Nipigon, on the north shore, is famous for speckled-trout (*Salvelinus fontinalis*, Mitchill) of unusual size; and all rivers and brooks falling into the lake are trout streams.

See Bulletin No. 17, *Survey of Northern and North-Western Lakes*, U.S. War Department, Lake Survey Office, Detroit (1907); *Sailing Directions for Lake Superior and the St Mary's River*, U.S. Hydrographic Office publication No. 108 A. (Washington, 1906), with supplements. (W. P. A.)

SUPERIOR, a city, a port of entry and the county-seat of Douglas county, Wisconsin, U.S.A., about 140 m. N. by E. of Minneapolis and St Paul, on Superior, St Louis and Allouez bays at the head of Lake Superior, and directly opposite Duluth, Minnesota, with which it is connected by ferry and by railway and road bridges. Pop. (1890), 11,983; (1900), 31,091, of whom 11,419 were foreign-born (2854 Swedish, 2404 English Canadians, 2026 Norwegian, and 801 German), and 186 were negroes; (1910, U.S. census), 40,384. Superior is served by the Northern Pacific, the Duluth, South Shore & Atlantic, the Wisconsin Central, the Great Northern, the Minneapolis, St Paul & Sault Ste Marie, and the Chicago & North-Western railways, and (for freight only) by the Chicago, Milwaukee & St Paul. A belt line railway connects the several systems. Superior shares with Duluth one of the finest natural inland harbours in the world. The harbour, which has been improved by the Federal government, is formed by two narrow strips of sandy land, known as Minnesota and Wisconsin Points, which extend several miles across the head of the lake from the Minnesota and Wisconsin shores respectively and almost meet in the centre. The body of water thus formed, Superior and Allouez bays, varies in width from 1 to $1\frac{1}{4}$ m., and is $9\frac{1}{2}$ m. long. St Louis Bay, on the west, is about $1\frac{1}{2}$ by 4 m. The city is situated on gently rising ground facing these bays, and has 29 m. of harbour frontage. The settlement of Superior at different times and in different places is responsible for the large area covered by the city (36·1 sq. m.) and its appearance is that of three distinct towns. The intervening portions have however been platted and are now largely settled. Superior is the seat of a state normal school (1896), which occupies a splendidly equipped building, and, in addition to the ordinary normal courses, has departments of kindergarten training, manual training and domestic science. The city is the see of a Roman Catholic bishop. Superior has a cheap fuel supply and power is furnished by electricity generated on the St Louis river. In 1905 the value of its factory products was $6,356,981. Flour is the principal product, and shipbuilding is important. Among steel ships, the type known as the "whaleback" originated here; and iron and wooden ships, launches and small pleasure craft are also made. Other manufactures are railway cars, casks, cooperage, saw and planing mill products, furniture, wooden ware, windmills, gas-engines, and mattresses and wire beds. Superior is an important grain market. Much iron and copper ore is shipped from the Duluth-Superior harbour; and large quantities of coal, brought by lake boats, are distributed from here throughout the American and Canadian North-west. The total tonnage of the Duluth–Superior Harbour was estimated in 1908 to be exceeded in the United States only by that of New York and that of Philadelphia.

Pierre Esprit Radisson and Medard Chouart des Groseilliers probably visited the site of Superior in 1661, and it is practically certain that other French *coureurs-des-bois* were here at different times before Daniel Greysolon, Sieur Du Lhut (Duluth), established a trading post in the neighbourhood about 1678. About 1820 the Hudson's Bay Company established a post here, but there was no permanent settlement until after the middle of the 19th century. Attention was directed to the site by a survey made by George R. Stuntz, a government surveyor, in 1852, and in 1853 a syndicate of capitalists, at the head of which was William Wilson Corcoran, the wealthy Washington banker, associated with whom were Senators Stephen A. Douglas (from whom the county was named), R. M. T. Hunter and J. B. Bright, Ex-Senator Robert J. Walker, Congressmen John C. Breckinridge and John L. Dawson, and others, largely Southern politicians and members of Congress, bought lands here and platted a town which was named Superior. The proprietors secured in 1856 the construction of a military road to St Paul, Minnesota, 160 m. long. The town grew rapidly, and in 1856–1857 had about 2500 inhabitants. The panic of 1857 interrupted its growth, and the population dwindled so that in 1860 there were only a few hundred settlers on the town-site. The Civil War increased the depression, and the lands of those who had taken part against the Union were confiscated. In 1862 a series of stockades was built as a protection from the Indians. Within the area under the government of the town of Superior, which was at first co-extensive with the county, West Superior was platted in 1883 and South Superior soon afterwards. A village government was established in September 1887, including the three settlements mentioned, and in April 1889 Superior was chartered as a city. The harbour was surveyed in 1823–1825 by Lieut. Henry Wolsey Bayfield (1795–1885) of the British Navy. In 1860–1861 it was resurveyed by Captain George G. Meade, who was engaged in the work at the outbreak of the Civil War. A branch of the Northern Pacific railway was built to Superior in 1881.

SUPPÉ, FRANZ VON (1820–1895), Austrian musical composer, whose real name was Francesco Ezechiele Ermenegildo Suppé-Demelli, was born at Spalato, in Dalmatia, in 1820, and died at Vienna in 1895. Originally he studied philosophy at the university of Padua, but on the death of his father devoted himself to music, studying at the Vienna conservatoire. He began his musical career as a conductor in one of the smaller Viennese theatres, and gradually worked his way up to be one of the most popular composers of ephemeral light opera of the day. Outside Vienna his works never won much success. Of his sixty comic operas *Fatinitza* (Vienna, 1876; London, 1878) was the most successful, while *Boccaccio* (Vienna, 1879; London, 1882) only enjoyed moderate favour. Suppé's overture to *Dichter und Bauer* is his most successful orchestral work. He also wrote some church music.

SUPPLY (through Fr. from Lat. *supplere*, to fill up), provision; more particularly the money granted by a legislature to carry on the work of government. In the United Kingdom the granting of supply is the exclusive right of the House of Commons, and is carried out by two committees of the House, one of supply and the other of ways and means (see PARLIAMENT). In the United States supply originates in the House of Representatives (see UNITED STATES: *Appropriation*).

In Scotland commissioners of supply were officers appointed to assess and collect the land tax offered as supply to the sovereign. Under the Lands Valuation (Scotland) Act 1854 all owners of property of a certain value were qualified as commissioners of supply. Their duties were also enlarged to comprise the general administration of the country, but by the Local Government (Scotland) Act 1889 all their powers and duties were transferred to and vested in the county council. They still meet annually, but transact only formal business.

SUPPLY AND TRANSPORT, MILITARY. In all ages the operations of armies have been influenced, and in many cases absolutely controlled, by the necessity of providing and distributing food, forage and stores for men and horses. In modern history these supplies have become more and more varied as weapons developed in complexity, power and accuracy of workmanship. In proportion, the branches of an army which are charged with the duties of "supply and transport" have become specialized as regards recruiting, training and organization.

The predatory armies of the middle ages not only lived upon the country they traversed, but enriched themselves with the plunder they obtained from it, and this method of subsisting and paying an army reached its utmost limits in the Thirty Years' War. During the last stages of this war Germany had been so thoroughly devastated that the armies marched hither and thither like packs of hungry wolves, every soldier accompanied by two or three non-combatants—camp followers of all sorts, mistresses, ragged children and miserable peasants who had lost all and now sought to live by robbing others under the protection of the army. An English traveller, as early as 1636, twelve years before the peace of Westphalia, reported that at Bacharach-on-Rhine he had found "the poor people dead with grass in their mouths," and that a village at which he stayed "hath been pillaged eight-and-twenty times in two years, and twice in one day."

From these horrors there followed a revulsion to the other extreme. Unless ordered by higher authority for political reasons to sack a particular town or to pillage a particular district, the soldiers were rigidly kept in hand, rationed by their own supply officers and hanged or flogged if at any moment an outbreak of the old vices made the example necessary. After 1648 there were very few districts in Middle Europe that could support an army for even a few days, and the burden of their sustenance had to be distributed over a larger area. Thus, at the mere rumour of an army's approach, the peasantry fled with all their belongings into the fortified places, armies soon came to be supplied from "magazines," which were filled either by contract from the home country or by inducing the peasantry—by means of good conduct and cash payments—to bring their produce to market. These magazines were placed in a strong place, and if one was not available, a siege had to be undertaken to meet the demand. Moreover, soldiers in Marlborough's time were not as easily obtained as in the Thirty Years' War, and they had to be housed and fed comfortably enough to make it worth their while to stay with the colours instead of deserting. From these and similar conditions there grew up a system of supply and transport usually called the "magazine system," under which an army was bound, under penalty of dissolution, to go no farther than seven marches from the nearest fortress, two days from the nearest field bakery, and so on. When an 18th-century army foraged for itself it was because the regular supply service was interrupted, *i.e.* when it was *in extremis*. But the relative rarity of wars in the 18th century, the habit of demanding nothing from the inhabitants of the country traversed by an army, and the virtual exclusion of the people from the prince's quarrels, gave Europe a century's respite in which to recover from the drain of the Thirty Years' War. And therefore, when the French Revolution came, the attempts of the armies of old Europe to suppress it without robbing a single Frenchman of a loaf of bread proved futile, and soon the national army created by the Revolution, unencumbered by tents, magazines and supply trains, swept over southern Germany and Italy. The Revolutionary armies differed indeed from those of the old wars in this, that they did not devastate wantonly, nor did they murder for the sake of loot. But they were merciless in their exactions, and, moreover, the tides of their invasions flowed in particular channels, so that the greater part of the invaded country escaped. This had a considerable, sometimes even a predominant, influence on the strategy pursued, a retreat along their own lines of communication being often in fact avoided by the French as being the worst fate that could befall them. Napoleon, however, systematized the wasteful and irregular requisitioning that his predecessors had introduced, and in his hands the supply service, like all else connected with the art of war, underwent a thorough reform. His strategy[1] in the offensive passed through two distinct stages—(*a*) the swift and sudden descent into the theatre of war, and (*b*) the close grouping of his armies in view of the decisive blow. The first stage was characterized by extraordinarily swift movement, complete independence of all trains (other than the reserves of ammunition) and thorough exploitation of the food resources of the traversed zone. If the troops suffered, as well as the inhabitants, this did not shake the emperor's purpose in the slightest. If all the disorders which are the natural consequence of ill-regulated requisitioning—that is, marauding—cost the army 50,000 men, he had foreseen the loss and taken 50,000 men more than he needed for the battle. But the second stage, which as a rule involved three or four days' occupation, without considerable movement, of a restricted area, required other measures of supply. In this the army lived upon magazines, which were filled from the captured supply trains from the available supplies in the area, and from the resources accumulated in requisitioned vehicles close to the head of the routes followed in the first period. These resources were collected in the towns within this concentration area, and placed "out of reach of an insult" (that is, made safe against raiders) with a garrison and field works to supplement the town walls and gates. From this *centre of operations* Napoleon never allowed himself to be severed, whereas to the preservation of the route between France and that centre of operations he gave very little thought and assigned few or no troops, and most of the confusion of strategical thought since his time has been due to the general failure to perceive the essential distinction, in Napoleonic practice, between a centre of operations and a "base."

In the 19th century, however, there came the inevitable reaction. Purely political wars, and the consequent indifference of the inhabitants to the operations of war, produced as before a return to the system of cash payments and convoy supply, especially in the Austrian army. As regards Europe the introduction of railways enormously facilitated the supply and transport service, and campaigns were neither as barren nor as prolonged as they had been under the old conditions. The French and British armies did not, at least to the same extent, wage political wars, but their ceaseless colonial warfare imposed upon them the magazine and convoy system, and habituated them to it. The French, in 1870, stood still in the midst of the rich fields of Lorraine, and as a prolonged halt is fatal to the system of living on the country, it would have failed, even had it been tried. The Germans, on the other hand, levied requisitions, civilian transport, and contributions in money in accordance with Napoleonic tradition, though (owing to the existence of railways) with much less than Napoleonic severity. Their system has been accepted as the best for European warfare by all the great powers, whose organizations and methods of transporting and issuing supplies are the same in principle.

This principle is based on the Napoleonic distinction between supplies required during an advance and those required during a concentrated halt. The British *Field Service Regulations* (1909), pt. ii., lay it down that "the system of subsistence should be elastic and readily adaptable to every situation as it arises," but that it must always be based on the rule that "all mobile supplies are to be regarded as a *reserve*" for use when neither local nor line-of-communication resources are available. As a general rule local resources should be used before the line of communication is called upon, and last of all the call is made on the mobile supplies in the hands of the fighting units. During a strategical concentration or a long halt "the resources of the immediate neighbourhood cannot be expected to support the troops. At such times they may be supplied from field dépôts established at convenient centres, and filled with supplies that are obtained by purchase or requisition and collected by requisitioned or hired (civilian) transport." During an advance, on the other hand, "by far the most advantageous method is for the troops to be rationed by the inhabitants on whom they are billeted . . . This method should be employed whenever possible."

The extent to which it can be employed varies considerably with the place and the season, but the British and all continental armies have their own "rules of thumb" or rough generalizations based on experience. General Lewal (*Stratégie de marche*, p. 47) says that in a country of ordinary fertility, with 70 inhabitants to the square kilometre, or 180 to the square mile, 10,000 men can be subsisted for one day on an area of 22 square

[1] H. Camon, *Guerre napoléonienne.*

kilometres or 8½ square miles, or 1200 per square mile. General Bonnal in his *Sadowa* gives 36 square miles as sufficient for the maintenance of an army corps (30,000–35,000) or about 1100 men to the square mile during the assembly period, but only on condition of helping out local resources by special supplies from the base. The British *Field Service Regulations* state that ordinary agricultural districts of Western Europe, not previously traversed by troops, will support a force of twice the strength of the population for a week at a maximum. This would mean exacting fourteen rations from each inhabitant, but the incidence of the burden is spread over several days. A practical rule therefore would seem to be, in a district of 200 inhabitants to the square mile, to allot 1400 men per square mile for a flying passage of one day and 400 for a stay of one week, the resources of the country being more thoroughly and systematically exploited in the latter case. A British division (combatant column only) closing up to half its marching depth at the end of the day would require 12 square miles, and as its depth would be about 5½ miles, its front or width would perhaps extend for only a mile on either side of the route. It is quite possible to move two divisions for several consecutive days on the same road, living on the country exclusively, subject to the condition that the second should halt on the areas which the first has passed through without stopping. In continental armies the rule is, in fact, "one army corps (=2 British divisions) on one road."

During the period of concentration, however, even if in movement, a modern army will necessarily be supplied in somewhat the same way as Napoleon's. The billets will be allotted "without subsistence," and the regimental reserve supplies will be called upon to ration their men, while all around the occupied towns and villages the supply officers and their mounted escorts will requisition food and vehicles to bring the food into the concentration area. In view of this, "supply officers will be sent on with cavalry or mounted brigades to investigate the resources of the country ahead of the main body, and if possible to collect supplies at suitable points." Only commissioned officers and, as a rule, only those officers to whom the power is expressly delegated are entitled to carry out requisitions, though in an emergency a commander of any rank may obtain from the inhabitants articles or services by requisition and on his own responsibility, which responsibility may mean answering to a charge of "plundering" before a court-martial. On purely requisitioning work direct contact between the troops and the inhabitants is to be avoided.

Generally, then, a British regiment operating in Europe would be fed, during an advance, (*a*) by the inhabitants who provide the billets, without the necessity of a supply officer's intervention, (*b*) by the regimental reserves, which would be filled up as they were emptied from the field dépôts, of food-stuffs requisitioned by the supply officers, or (*c*) on emergency by direct requisitioning. During a concentration it would be fed (*a*) in the first instance by "billets with subsistence," as in an advance, (*b*) in so far as this was insufficient, by regimental, brigade and divisional reserves, which would refill partly from the lines of communication and partly from the field dépôts created by the requisitioning supply officers. Thus, as regards food and forage, the British Regulations—though it was not until 1909 that they appeared—are based on the fundamental principles of Napoleon that strategy must be the master, not the servant of supply, and that this mastery is most complete when—by means of "billets with subsistence" or by means of field dépôts of requisitioned food-stuffs—an army makes itself practically independent, as regards food, of its lines of communication.

The general organization of the supply service in Great Britain, calculated for a campaign under European conditions, is as follows: There are dépôts of various kinds and "mobile supplies." The former are classified as (*a*) *base dépôt*, which is the great reserve magazine that collects all resources that come from outside the theatre of war; (*b*) *intermediate dépôts* (filled from the base or by local requisitioning) at intervals along the line of communication, which serve principally to feed the troops posted on the line of communication and those passing along it to the front, but can also be used as an "overflow" magazine if the base dépôt is full, and as a means of bringing reserves nearer to the front: (*c*) *advanced dépôts* at the head of the line of communication, which serve as the expense-magazine, issuing to the "mobile supplies" what these need to enable them to supplement local resources; (*d*) *field dépôts*, frequently alluded to above, which are small temporary dépôts (filled by requisitioning) in the immediate neighbourhood of the front, and from which, in preference to their own mobile reserves, the troops draw supplies if the inhabitants do not furnish them directly in the billets; field dépôts may also be utilized for storing local supplies surplus to the immediate wants of the army. The "mobile supplies" are classified as follows: (*a*) *Regimental*, which are carried partly by man and horse in the ranks and partly in "regimental transport" vehicles, and consist of the current day's ration and the "emergency ration" of compressed food (which is never to be used except in an extremity) on man or horse, and a complete ration for every man and horse on the ration strength of the unit, with an extra "grocery ration" and some compressed forage in the vehicles. (*b*) *Column*, which are carried in the Army Service Corps "supply columns" of the division and carry one day's complete ration[1] and one emergency ration per head of men and animals—these are in a sense mobile field dépôts and depend either on requisitioning or on the advanced dépôt of the line of communication. (*c*) *Park*, which are carried in "divisional parks" that move a day's march (often more) in rear of the divisions and comprise a last mobile reserve of three days' rations of food and forage for the troops.

In warfare in savage or undeveloped countries the conditions are far less favourable, and each case has to be dealt with on its merits. But, in general, such warfare always necessitates an almost complete dependence on magazine supply. There are few or no "billets with subsistence" or "field dépôts" which are the backbone of the supply system in European warfare, and the regimental and column supply vehicles have generally such difficulty in keeping touch with the advanced dépôt of the line of communication that the striking radius of the army is strictly limited to the position and output of the line of communications. Moreover, the difficulty—even the principal difficulty—is the transport of the supplies obtained from the line of communication. The alternative, which has often to be adopted by "punitive" expeditions, is to carry all supplies for the calculated duration of the movements with the troops, but the penalty for this freedom to move is either slowness of movement—the fighting troops regulating their pace by that of the supply vehicles or pack animals—or a disproportionate number of "useless mouths" or non-combatants who must be fed. Altogether, the supply difficulty in expeditions in the Sudan, or West Africa, or on the Indian frontier infinitely outweighs all difficulties of country or enemy. Moreover, paradoxical as it may be, the triumphant surmounting of these difficulties has its disadvantages as regards European warfare. Generals and supply officers who have always dealt with the maximum of difficulty find it almost impossible to bring themselves to deal with easier conditions. In 1805 Mack vainly sought to teach the Austrian soldier how to live on the country in the Napoleonic fashion. In 1806 the Prussians starved in the midst of riches, in 1870 the French moved as slowly and kept themselves as closely concentrated as desert columns in Algeria, and so deprived themselves of the resources of their own country.

Military transport—other than water and rail—may be classed in respect of the means employed as draught and pack, and in respect of its organization and functions as transport on the line of communications and transport in the field, the latter being subdivided into first line and second line. The British army, on account of its frequent expeditions into undeveloped countries, makes a large—in the view of many, far too large—use of pack transport, for which mules, camels and human carriers are employed. But in

[1] One day's supply of meat is usually taken with the column "on the hoof."

European, and to a large extent in other warfare, horsed transport is by far the most generally used. Mechanical transport (generally either traction engines with trucks or motor lorries) is, however, superseding horse draught to a considerable extent in second-line transport. The vehicle usually employed for military transport is the "General Service Wagon," a heavily-built springless four-wheeled vehicle drawn by six or four horses according to circumstances, which weighs empty about 18 cwt., and allows of a maximum load of 30 cwt. There are also four-horse "limbered wagons" consisting of body and limber, weighing 13 cwt. empty and 43 cwt. fully loaded, and lighter two-wheeled carts which can take 13–15 cwt. load.

As regards organization and functions, road transport is used on the line of communications to supplement the railway, and consists of locally hired or requisitioned vehicles worked by the Army Service Corps, or by civilian personnel under A.S.C. control. Transport with the field units is, as has been said, divided into first line, which accompanies the fighting troops, and second line, which follows them at a distance. Both lines are, as a rule, manned exclusively by the A.S.C. (or regimental details in the case of regimental transport) and composed of regulation-pattern carts and wagons. The first-line vehicles include ammunition wagons and carts, tool carts, engineer vehicles and medical vehicles. All baggage and store and supply wagons, as well as a proportion of medical, ammunition and engineer vehicles, form the second line.

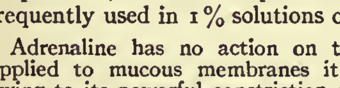
(C. F. A.)

SUPRA-RENAL EXTRACT. The extract of the supra-renal gland is one of the most valuable remedies recently introduced in medicine. Feeding with the fresh gland of sheep was at first practised, but the sterilized glycerin preparation known as supra-renal extract is now used, the dose being 5 to 15 minims. The active principle of the gland,. best known as adrenaline or epinephrine, occurs only in the medulla of the gland. It forms minute white crystals, soluble in weak solutions of hydrochloric acid. The U.S.P. contains a desiccated preparation, *Glandulae suprarenales siccae*. Adrenaline is most frequently used in 1% solutions of the chloride.

Adrenaline has no action on the unbroken skin, but locally applied to mucous membranes it causes blanching of the part owing to its powerful constriction of the capillaries by stimulating the muscular fibres of the vessel walls. It acts rapidly in a similar manner when hypodermically injected. The vessels of the uterus are strongly acted upon by it, but the effect on the cerebral vessels is slight, and the pulmonary vessels are unaffected. The heart is slowed and the systole increased. Adrenaline stimulates the salivary glands. It also produces a temporary glycosuria. In poisonous doses it causes haemorrhages into the viscera and oedema of the lungs.

In Addison's disease the use of supra-renal extract has been beneficial in some cases, but its chief use is in the control of haemorrhage. For this purpose it is given in conjunction with local anaesthetics such as cocaine in order to produce bloodless operations on the eye, nose and elsewhere. It is also useful in haemorrhage from small vessels, where it can be applied at the bleeding spot, as in epistaxis. In menorrhagia and metrorrhagia it is also of service. In surgical shock and in chloroform syncope an injection of adrenaline often saves life through the rise of blood pressure produced. An attack of bronchial asthma may be cut short by a hypodermic injection of adrenaline solution. It should never be used in the treatment of haemoptysis. Similar commercial products on the market are hemisine, renaglandine, suprarenine, adnephrine, paranephrine and renostyptine. Supra-renal snuff containing the dry extract with menthol and boric acid is of use in hay fever. Rhinodyne is of this type. Suppositories containing supra-renal extract are used to check bleeding piles.

The chemistry of adrenaline has been mainly elucidated by the investigations of Pauly, Jowett and Bertrand; Jowett proposing a constitution (see annexed formula) now accepted as correct.



Adrenaline.

Many substances having related constitutions have been synthesized, and it has been found that they resemble adrenaline in increasing the blood pressure. For example, the corresponding ketone, adrenalone (obtained in 1904 by Stolz) is active, and the methyl group can be replaced by hydrogen or another radical without destroying the activity. It seems that the para-hydroxyl group is essential. For instance, para-hydroxyphenylethylamine, $HO{\cdot}C_6H_4CH_2{\cdot}CH_2NH_2$, which is one of the active bases of ergot, closely resembles adrenaline (G. Barger, *Journ. Chem. Soc.*, 1909, 95, pp. 1123, 1720; K. W. Rosenmund, *Ber.*, 1909, 42, p. 4778); as does also its dimethyl derivative hordenine, an alkaloid found in barley (G. Barger, ibid., p. 2193). Adrenaline is optically active, the naturally occurring isomer being the laevo form; it is interesting to note that, like nicotine, the laevo base has a much greater physiological activity than the dextro.

SUPREME COURT OF JUDICATURE, in England, a court of law established by the Judicature Act 1873, by section 3 of which it was provided that the high court of chancery, the courts of king's bench, common pleas, and exchequer, the high court of admiralty, the court of probate and the divorce court, should be united under this name. By section 4, the Supreme Court was to consist of two divisions, one to be called the "high-court of justice" and the other the "court of appeal." See further under JUDICATURE ACTS, and also the articles under the headings of the different courts enumerated above.

The Supreme Court of the United States is the head of the national judiciary. Its establishment was authorized by article iii. of the Constitution, which states that "the judicial power of the United States shall be vested in one Supreme Court, and in such inferior courts as the Congress may from time to time ordain and establish" (s. i.). Section ii. states that "the judicial power shall extend to all cases in law and equity arising under this Constitution, the laws of the United States, and treaties made, or which shall be made, under their authority; to all cases affecting ambassadors, other public ministers and consuls; to all cases of admiralty and maritime jurisdiction; to controversies between two or more states, between a state and citizens of another state, between citizens of different states, between citizens of the same state claiming lands under grants of different states, and between a state, and the citizens thereof, and foreign states, citizens, or subjects. In all cases affecting ambassadors, other public ministers and consuls, and those in which a state shall be party, the Supreme Court shall have original jurisdiction. In all the other cases before mentioned the Supreme Court shall have appellate jurisdiction both as to law and fact, with such exceptions and under such regulations as the Congress shall make." The Supreme Court of the United States also occupies the unique position of being guardian of the Constitution. It has to decide whether a measure passed by the legislative powers is unconstitutional or not, and it may thus have to veto the deliberate resolutions of both houses of Congress and the president.

See UNITED STATES.

SURABAYA (Dutch *Soerabaja*), a seaport of Java, in the eastern division of the island, on the narrow Surabaya strait, which separates the island of Madura from Java, and at the mouth of the Kali Mas River. Pop. (1900), 146,944 (Europeans 8906; Chinese 13,035). Surabaya is the principal mercantile town in Java. Its roadstead is sheltered by Madura, and it has important dockyards. It is also the headquarters of the military authorities for East Java, and has artillery workshops. Railways running north-west, south-west and south give it connexions throughout the island. In the old town, with its partly demolished fortifications, houses, shops and warehouses are more closely packed and the streets are narrower than in most East Indian towns, and, although a considerable number of Europeans live in this quarter, the outlying quarters, such as Simpang (where is the government house) and Tuntungan, are preferable for residence.

SURAJ-UD-DOWLAH (d. 1757), ruler of Bengal. The date of his birth is uncertain, but is generally placed between 1729 and 1736. His name was Mirza Mahommed, and he succeeded his grandfather Aliverdi Khan as nawab of Bengal on the 9th of April 1756. He was a cruel and profligate fanatic. Being offended with the English for giving protection to a native official who had escaped with treasure from Dacca, he attacked and took Calcutta on the 20th of June 1756. He then permitted the massacre known in history as "The Black Hole of Calcutta" (see CALCUTTA). This atrocious act was soon avenged. Calcutta was retaken by Clive and Admiral Watson on the 2nd of January 1757, and on the 23rd of June, Suraj-ud-Dowlah, routed at Plassey, fled to Rajmahal, where he was captured. He was put to death on the 4th of July 1757 at Murshidabad, by order of Miran, son of Mir Jafar, who had conspired against Suraj-ud-Dowlah and had been present at Plassey without taking part in the battle.

SURAT, a city and district of British India in the northern division of Bombay. The city is on the site where the English first established a factory on the mainland, and so planted the seed of the British Empire in India. Local traditions fix the establishment of the modern city in the last year of the fifteenth century, and in 1514 the Portuguese traveller Barbosa described it as an important seaport, frequented by many ships from Malabar and all parts. During the reigns of Akbar, Jahangir and Shah Jahan it rose to be the chief commercial city of India. At the end of the 16th century the Portuguese were undisputed masters of the Surat seas. But in 1612 Captain Best, and after him Captain Downton, destroyed the Portuguese naval supremacy and obtained an imperial firman making Surat the seat of a presidency under the English East India Company, while the Dutch also founded a factory. In 1664 Sir George Oxenden defended the factory against Sivaji with a bravery that deserves to rank with Clive's defence of Arcot. The prosperity of the factory at Surat received a fatal blow when Bombay was ceded to the Company (1668) and shortly afterwards made the capital of the Company's possessions and the chief seat of their trade. From that date also the city began to decline. At one time its population was estimated at 800,000, by the middle of the 19th century the number had fallen to 80,000; but in 1901 it had risen again to 119,306. Surat was taken by the English in 1759, and the conquerors assumed the undivided government of the city in 1800. Since the introduction of British rule the district has remained comparatively tranquil; and even during the Mutiny peace was not disturbed, owing in great measure to the loyalty of the leading Mahommedan families.

The city is situated on the left bank of the river Tapti, 14 m. from its mouth, and has a station on the Bombay, Baroda & Central India railway, 167 m. north of Bombay. A moat indicates the dividing-line between the city, with its narrow streets and handsome houses, and the suburbs, mostly scattered among cultivated lands; but the city wall has almost disappeared. On the river frontage rises the irregular picturesque fortress built about 1540. A fire and a flood in 1837 destroyed a great number of buildings, but there remain several of interest, such as the mosque of Nav Saiyid Sahib, with its nine tombs, the Saiyid Edroos mosque (1634) and the ornate Mirza Sami mosque and tomb (1540). The most interesting monuments are the tombs of English and Dutch merchants of the 17th century, especially that of the Oxenden brothers. Surat is still a centre of trade and manufacture, though some of its former industries, such as ship-building, are extinct. There are cotton mills, factories for ginning and pressing cotton, rice-cleaning mills and paper mills. Fine cotton goods are woven in hand-looms, and there are special manufactures of silk brocade and embroidery. The chief trades are organized in gilds. There are many wealthy Parsee, Hindu and Mahommedan merchants.

The District of Surat has an area of 1653 sq. m., and the population in 1901 was 637,017, showing a decrease of 2% in the decade. The district has a coast-line of 80 m., consisting of a barren stretch of sand drift and salt marsh; behind this is a rich, highly-cultivated plain, nearly 60 m. in breadth, at the mouth of the Tapti, but narrowing to only 15 m. in the southern part, and on the north-east are the wild hills and jungle of the Dangs. The principal crops are millets, rice, pulses, cotton and a little wheat. After Surat city the chief centre of trade is Bulsar. The district is traversed by the main line of the Bombay & Baroda railway, with a branch along the Tapti valley to join the Great Indian Peninsula railway in Khandesh. Near the coast, under the influence of the sea breeze, an equable temperature prevails, but 8 to 11 m. inland the breeze ceases to blow. The coast also possesses a much lighter rainfall than the interior, the annual average ranging from 30 in. in Olpad to 72 in Chikhli, while at Surat city the average is 39½ in.

The Surat Agency consists of three native states: Dharampur (*q.v.*), Bansda (*q.v.*) and Sachin, together with the tract known as the Dangs. Total area, 1960 sq. m.; pop. (1901), 179,975. Sachin has a revenue of £17,000 and its chief is a Mahommedan.

SURBASE (Lat. *super*, whence the Fr. *sur*, above or upon, and base, *q.v.*), *i.e.* upper base, the term in architecture applied to what, in the fittings of a room, is called the chair-rail. It is also used to distinguish the cornice of a pedestal or podium and is separated from the base by the dado or die.

SURBITON, an urban district in the Kingston parliamentary division of Surrey, England, 13 m. S.W. of Charing Cross, London; on the London & South-Western railway. Pop. (1891), 12,178; (1901), 15,017. It has a frontage upon the right bank of the Thames, with a pleasant esplanade. The district is largely residential. Surbiton is the headquarters of the Kingston Rowing Club and the Thames Sailing Club.

SURETY, in law, the party liable under a contract of guarantee (*q.v.*). In criminal practice sureties bound by recognizance (*q.v.*) are a means of obtaining compliance with the order of a court of justice, whether to keep the peace or otherwise.

SURFACE, the bounding or limiting parts of a body. In the article Curve the mathematical question is treated from an historical point of view, for the purpose of showing how the leading ideas of the theory were successively arrived at. These leading ideas apply to surfaces, but the ideas peculiar to surfaces are scarcely of the like fundamental nature, being rather developments of the former set in their application to a more advanced portion of geometry; there is consequently less occasion for the historical mode of treatment. Curves in space are considered in the same article, and they will not be discussed here; but it is proper to refer to them in connexion with the other notions of solid geometry. In plane geometry the elementary figures are the point and the line; and we then have the curve, which may be regarded as a singly infinite system of points, and also as a singly infinite system of lines. In solid geometry the elementary figures are the point, the line and the plane; we have, moreover, first, that which under one aspect is the curve and under another aspect the developable (or torse), and which may be regarded as a singly infinite system of points, of lines or of planes; and secondly, the surface, which may be regarded as a doubly infinite system of points or of planes, and also as a special triply infinite system of lines. (The tangent lines of a surface are a special complex.) As distinct particular cases of the first figure we have the plane curve and the cone, and as a particular case of the second figure the ruled surface, regulus or singly infinite system of lines; we have, besides, the congruence or doubly infinite system of lines and the complex or triply infinite system of lines. And thus crowds of theories arise which have hardly any analogues in plane geometry; the relation of a curve to the various surfaces which can be drawn through it, and that of a surface to the various curves which can be drawn upon it, are different in kind from those which in plane geometry most nearly correspond to them—the relation of a system of points to the different curves through them and that of a curve to the systems of points upon it. In particular, there is nothing in plane geometry to correspond to the theory of the curves of curvature of a surface. Again, to the single theorem of plane geometry, that a line is the shortest distance between two points, there correspond in solid geometry two extensive and difficult theories—that of the geodesic lines on a surface and that of the minimal surface, or surface of minimum area, for a given boundary. And it would be easy to say more in illustration of the great extent and complexity of the subject.

In Part I. the subject will be treated by the ordinary methods of analytical geometry; Part II. will consider the Gaussian treatment by differentials, or the E, F, G analysis.

Part I.

Surfaces in General; Torses, &c.

1. A surface may be regarded as the locus of a doubly infinite system of points—that is, the locus of the system of points determined by a single equation $U=(*\between x, y, z, 1)^n, =0$, between the cartesian co-ordinates (to fix the ideas, say rectangular co-ordinates) x, y, z; or, if we please, by a single homogeneous relation $U=(*\between x, y, z, w)^n, =0$, between the quadriplanar co-ordinates x, y, z, w.

The degree n of the equation is the order of the surface; and this definition of the order agrees with the geometrical one, that the order of the surface is equal to the number of the intersections of the surface by an arbitrary line. Starting from the foregoing point definition of the surface, we might develop the notions of the tangent line and the tangent plane; but it will be more convenient to consider the surface *ab initio* from the more general point of view in its relation to the point, the line and the plane.

2. Mention has been made of the plane curve and the cone; it is proper to recall that the *order* of a plane curve is equal to the number of its intersections by an arbitrary line (in the plane of the curve), and that its *class* is equal to the number of tangents to the curve which pass through an arbitrary point (in the plane of the curve). The cone is a figure correlative to the plane curve: corresponding to the plane of the curve we have the vertex of the cone, to its tangents the generating lines of the cone, and to its points the tangent planes of the cone. But from a different point of view we may consider the generating lines of the cone as corresponding to the points of the curve and its tangent planes as corresponding to the tangents of the curve. From this point of view we define the order of the cone as equal to the number of its intersections (generating lines) by an arbitrary plane through the vertex, and its class as equal to the number of the tangent planes which pass through an arbitrary line through the vertex. And in the same way that a plane curve has singularities (singular points and singular tangents) so a cone has singularities (singular generating lines and singular tangent planes).

Order, Class and Rank.

3. Consider now a surface in connexion with an arbitrary line. The line meets the surface in a certain number of points, and, as already mentioned, the *order* of the surface is equal to the number of these intersections. We have through the line a certain number of tangent planes of the surface, and the *class* of the surface is equal to the number of these tangent planes.

But, further, through the line imagine a plane; this meets the surface in a curve the order of which is equal (as is at once seen) to the order of the surface. Again, on the line imagine a point; this is the vertex of a cone circumscribing the surface, and the class of this cone is equal (as is at once seen) to the class of the surface. The tangent lines of the surface which lie in the plane are nothing else than the tangents of the plane section, and thus form a singly infinite series of lines; similarly, the tangent lines of the surface which pass through the point are nothing else than the generating lines of the circumscribed cone, and thus form a singly infinite series of lines. But, if we consider those tangent lines of the surface which are at once in the plane and through the point, we see that they are finite in number; and we define the *rank* of a surface as equal to the number of tangent lines which lie in a given plane and pass through a given point in that plane. It at once follows that the class of the plane section and the order of the circumscribed cone are each equal to the rank of the surface, and are thus equal to each other. It may be noticed that for a general surface $(*\between x, y, z, w)^n, =0$, of order n without point singularities the rank is $a, =n(n-1)$, and the class is $n', =n(n-1)^2$; this implies (what is in fact the case) that the circumscribed cone has line singularities, for otherwise its class, that is the class of the surface, would be $a(a-1)$, which is not $=n(n-1)^2$.

4. The notions of the tangent line and the tangent plane have been assumed as known, but they require to be further explained in reference to the original point definition of the surface. Speaking generally, we may say that the points of the surface consecutive to a given point on it lie in a plane which is the tangent plane at the given point, and conversely the given point is the point of contact of this tangent plane, and that any line through the point of contact and in the tangent plane is a tangent line touching the surface at the point of contact. Hence we see at once that the tangent line is any line meeting the surface in two consecutive points, or—what is the same thing—a line meeting the surface in the point of contact counting as two intersections and in $n-2$ other points. But, from the foregoing notion of the tangent plane as a plane containing the point of contact and the consecutive points of the surface, the passage to the true definition of the tangent plane is not equally obvious. A plane in general meets the surface of the order n in a curve of that order without double points; but the plane may be such that the curve has a double point, and when this is so the plane is a tangent plane having the double point for its point of contact. The double point is either an acnode (isolated point), then the surface at the point in question is convex towards (that is, concave away from) the tangent plane; or else it is a crunode, and the surface at the point in question is then concavo-convex, that is, it has its two curvatures in opposite senses (see below, par. 16). Observe that in either case any line whatever in the plane and through the point meets the surface in the points in which it meets the plane curve, viz. in the point of contact, which *qua* double point counts as two intersections, and in $n-2$ other points; that is, we have the preceding definition of the tangent line.

Tangent Lines and Planes.

5. The complete enumeration and discussion of the singularities of a surface is a question of extreme difficulty which has not yet been solved.[1] A plane curve has point singularities and line singularities; corresponding to these we have for the surface isolated point singularities and isolated plane singularities, but there are besides continuous singularities applying to curves on or torses circumscribed to the surface, and it is among these that we have the non-special singularities which play the most important part in the theory. Thus the plane curve represented by the general equation $(*\between x, y, z)^n=0$, of any given order n, has the non-special line singularities of inflexions and double tangents; corresponding to this the surface represented by the general equation $(*\between x, y, z, w)^n=0$, of any given order n, has, not the isolated plane singularities, but the continuous singularities of the spinode curve or torse and the node-couple curve or torse. A plane may meet the surface in a curve having (1) a cusp (spinode) or (2) a pair of double points; in each case there is a singly infinite system of such singular tangent planes, and the locus of the points of contact is the curve, the envelope of the tangent planes the torse. The reciprocal singularities to these are the nodal curve and the cuspidal curve: the surface may intersect or touch itself along a curve in such wise that, cutting the surface by an arbitrary plane, the curve of intersection has at each intersection of the plane with the curve on the surface (1) a double point (node) or (2) a cusp. Observe that these are singularities not occurring in the surface represented by the general equation $(*\between x, y, z, w)^n=0$ of any order; observe further that in the case of both or either of these singularities the definition of the tangent plane must be modified. A tangent plane is a plane such that there is in the plane section a double point in addition to the nodes or cusps at the intersections with the singular lines on the surface.

Singularities.

6. As regards isolated singularities, it will be sufficient to mention the point singularity of the conical point (or cnicnode) and the corresponding plane singularity of the conic of contact (or cnictrope). In the former case we have a point such that the consecutive points, instead of lying in a tangent plane, lie on a quadric cone, having the point for its vertex; in the latter case we have a plane touching the surface along a conic; that is, the complete intersection of the surface by the plane is made up of the conic taken twice and of a residual curve of the order $n-4$.

7. We may, in the general theory of surfaces, consider either a surface and its reciprocal surface, the reciprocal surface being taken to be the surface enveloped by the polar planes (in regard to a given quadric surface) of the points of the original surface; or—what is better—we may consider a given surface in reference to the reciprocal relations of its order, rank, class and singularities. In either case we have a series of unaccented letters and a corresponding series of accented letters, and the relations between them are such that we may in any equation interchange the accented and the unaccented letters; in some cases an unaccented letter may be equal to the corresponding accented letter. Thus, let n, n' be as before the order and the class of the surface, but, instead of immediately defining the rank, let a be used to denote the class of the plane section and a' the order of the circumscribed cone; also let S, S' be numbers referring to the singularities. The form of the relations is $a=a'$ (=rank of surface); $a'=n\ (n-1)-S$; $n'=n\ (n-1)^2-S$; $a=n'\ (n'-1)-S'$; $n=n'\ (n'-1)^2-S'$. In these last equations S, S' are merely written down to denote proper corresponding combinations of the several numbers referring to the singularities collectively denoted by S, S' respectively. The theory, as already mentioned, is a complex and difficult one.

8. A torse or developable corresponds to a curve in space in the same manner as a cone corresponds to a plane curve: although capable of representation by an equation $U=(*\between x, y, z, w)^n=0$, and so of coming under the foregoing point definition of a surface, it is an entirely distinct geometrical conception. We may indeed, *qua* surface, regard it as a surface characterized by the property that each of its tangent planes touches it, not at a single point, but along a line; this is equivalent to saying that it is the envelope, not of a doubly infinite series of planes, as is a proper surface, but of a singly infinite system of planes. But it is perhaps easier to regard it as the locus of a singly infinite system of lines, each line meeting the consecutive line, or, what is the same thing, the lines being tangent lines of a curve in space. The tangent plane is then the plane through two consecutive lines, or, what is the same thing, an osculating plane of the curve, whence also the tangent plane intersects the surface in the generating line counting twice, and in a residual curve of the order $n-2$. The curve is said to be the edge of regression of the developable, and it is a cuspidal curve thereof; that is to say, any plane section of the developable has at each point of intersection with the edge of regression a cusp. A sheet of paper bent in any manner without crumpling gives a developable;

Torse or Developable.

[1] In a plane curve the only singularities which need to be considered are those that present themselves in Plücker's equations, for every higher singularity whatever is equivalent to a certain number of nodes, cusps, inflexions and double tangents. As regards a surface, no such reduction of the higher singularities has as yet been made.

but we cannot with a single sheet of paper properly exhibit the form in the neighbourhood of the edge of regression: we need two sheets connected along a plane curve, which, when the paper is bent, becomes the edge of regression and appears as a cuspidal curve on the surface.

It may be mentioned that the condition which must be satisfied in order that the equation $U=0$ shall represent a developable is $H(U)=0$; that is, the Hessian or functional determinant formed with the second differential coefficients of U must vanish in virtue of the equation $U=0$, or—what is the same thing—$H(U)$ must contain U as a factor. If in cartesian co-ordinates the equation is taken in the form $z-f(x, y)=0$, then the condition is $rt-s^2=0$ identically, where r, s, t denote as usual the second differential coefficients of z in regard to x, y respectively.

Regulus or Ruled Surface.

9. A regulus or ruled surface is the locus of a singly infinite system of lines, where the consecutive lines do not intersect; this is a true surface, for there is a doubly infinite series of tangent planes—in fact any plane through any one of the lines is a tangent plane of the surface, touching it at a point on the line, and in such wise that, as the tangent plane turns about the line, the point of contact moves along the line. The complete intersection of the surface by the tangent plane is made up of the line counting once and of a residual curve of the order $n-1$. A quadric surface is a regulus in a twofold manner, for there are on the surface two systems of lines each of which is a regulus. A cubic surface may be a regulus (see below, par. 11).

Surfaces of the Orders 2, 3 and 4.

Quadric Surfaces.

10. A surface of the second order or a quadric surface is a surface such that every line meets it in two points, or—what comes to the same thing—such that every plane section thereof is a conic or quadric curve. Such surfaces have been studied from every point of view. The only singular forms are when there is (1) a conical point (cnicnode), when the surface is a cone of the second order or quadricone; (2) a conic of contact (cnictrope), when the surface is this conic; from a different point of view it is a "surface aplatie" or flattened surface. Excluding these degenerate forms, the surface is of the order, rank and class each $=2$, and it has no singularities. Distinguishing the forms according to *reality*, we have the ellipsoid, the hyperboloid of two sheets, the hyperboloid of one sheet, the elliptic paraboloid and the hyperbolic paraboloid (see GEOMETRY: § *Analytical*). A particular case of the ellipsoid is the sphere; in abstract geometry this is a quadric surface passing through a given quadric curve, the circle at infinity. The tangent plane of a quadric surface meets it in a quadric curve having a node, that is, in a pair of lines; hence there are on the surface two singly infinite sets of lines. Two lines of the same set do not meet, but each line of the one set meets each line of the other set; the surface is thus a regulus in a twofold manner. The lines are real for the hyperboloid of one sheet and for the hyperbolic paraboloid; for the other forms of surface they are imaginary.

Cubic Surfaces.

11. We have next the surface of the third order or cubic surface, which has also been very completely studied. Such a surface may have isolated point singularities (cnicnodes or points of higher singularity), or it may have a nodal line; we have thus $21+2,=23$ cases. In the general case of a surface without any singularities, the order, rank and class are $=3$, 6, 12 respectively. The surface has upon it 27 lines, lying by threes in 45 planes, which are triple tangent planes. Observe that the tangent plane is a plane meeting the surface in a curve having a node. For a surface of any given order n there will be a certain number of planes each meeting the surface in a curve with 3 nodes, that is, triple tangent planes; and, in the particular case where $n=3$, the cubic curve with 3 nodes is of course a set of 3 lines; it is found that the number of triple tangent planes is, as just mentioned, $=45$. This would give 135 lines, but through each line we have 5 such planes, and the number of lines is thus $=27$. The theory of the 27 lines is an extensive and interesting one; in particular, it may be noticed that we can, in thirty-six ways, select a system of 6×6 lines, or "double sixer," such that no two lines of the same set intersect each other, but that each line of the one set intersects each line of the other set.

A cubic surface having a nodal line is a ruled surface or regulus; in fact any plane through the nodal line meets the surface in this line counting twice and in a residual line, and there is thus on the surface a singly infinite set of lines. There are two forms.

Quartic Surfaces.

12. As regards quartic surfaces, only particular forms have been much studied. A quartic surface can have at most 16 conical points (cnicnodes); an instance of such a surface is Fresnel's wave surface, which has 4 real cnicnodes in one of the principal planes, 4×2 imaginary ones in the other two principal planes, and 4 imaginary ones at infinity—in all 16 cnicnodes; the same surface has also 4 real+12 imaginary planes each touching the surface along a circle (cnictropes)—in all 16 cnictropes. It was easy by a mere homographic transformation to pass to the more general surface called the tetrahedroid; but this was itself only a particular form of the general surface with 16 cnicnodes and 16 cnictropes first studied by Kummer. Quartic surfaces with a smaller number of cnicnodes have also been considered.

Another very important form is the quartic surface having a nodal conic; the nodal conic may be the circle at infinity, and we have then the so-called anallagmatic surface, otherwise the cyclide (which includes the particular form called Dupin's cyclide). These correspond to the bicircular quartic curve of plane geometry. Other forms of quartic surface might be referred to.

Congruences and Complexes.

Congruences.

13. A congruence is a doubly infinite system of lines. A line depends on four parameters and can therefore be determined so as to satisfy four conditions; if only two conditions are imposed on the line we have a doubly infinite system of lines or a congruence. For instance, the lines meeting each of two given lines form a congruence. It is hardly necessary to remark that, imposing on the line one more condition, we have a ruled surface or regulus; thus we can in an infinity of ways separate the congruence into a singly infinite system of reguli or of torses (see below, par. 16).

Considering in connexion with the congruence two arbitrary lines, there will be in the congruence a determinate number of lines which meet each of these two lines; and the number of lines thus meeting the two lines is said to be the *order-class* of the congruence. If the two arbitrary lines are taken to intersect each other, the congruence lines which meet each of the two lines separate themselves into two sets—those which lie in the plane of the two lines and those which pass through their intersection. There will be in the former set a determinate number of congruence lines which is the *order* of the congruence, and in the latter set a determinate number of congruence lines which is the *class* of the congruence. In other words, the order of the congruence is equal to the number of congruence lines lying in an arbitrary plane, and its class to the number of congruence lines passing through an arbitrary point.

The following systems of lines form each of them a congruence: (A) lines meeting each of two given curves; (B) lines meeting a given curve twice; (C) lines meeting a given curve and touching a given surface; (D) lines touching each of two given surfaces; (E) lines touching a given surface twice, or, say, the bitangents of a given surface.

The last case is the most general one; and conversely for a given congruence there will be in general a surface having the congruence lines for bitangents. This surface is said to be the *focal surface* of the congruence; the general surface with 16 cnicnodes first presented itself in this manner as the focal surface of a congruence. But the focal surface may degenerate into the forms belonging to the other cases A, B, C, D.

Complexes.

14. A complex is a triply infinite system of lines—for instance, the tangent lines of a surface. Considering an arbitrary point in connexion with the complex, the complex lines which pass through the point form a cone; considering a plane in connexion with it, the complex lines which lie in the plane envelop a curve. It is easy to see that the class of the curve is equal to the order of the cone; in fact each of these numbers is equal to the number of complex lines which lie in an arbitrary plane and pass through an arbitrary point of that plane; and we then say *order* of complex = order of curve; *rank* of complex = class of curve = order of cone; *class* of complex = class of cone. It is to be observed that, while for a congruence there is in general a surface having the congruence lines for bitangents, for a complex there is not in general any surface having the complex lines for tangents; the tangent lines of a surface are thus only a special form of complex. The theory of complexes first presented itself in the researches of Malus on systems of rays of light in connexion with double refraction.

15. The analytical theory as well of congruences as of complexes is most easily carried out by means of the six co-ordinates of a line; viz. there are co-ordinates (a, b, c, f, g, h) connected by the equation $af+bg+ch=0$, and therefore such that the ratios $a:b:c:f:g:h$ constitute a system of four arbitrary parameters. We have thus a congruence of the order n represented by a single homogeneous equation of that order $(*\between a, b, c, f, g, h)^n=0$ between the six co-ordinates; two such relations determine a congruence. But we have in regard to congruences the same difficulty as that which presents itself in regard to curves in space: it is not every congruence which can be represented completely and precisely by *two* such equations (see GEOMETRY: § *Line*).

The linear equation $(*\between a, b, c, f, g, h)=0$ represents a congruence of the first order or linear congruence; such congruences are interesting both in geometry and in connexion with the theory of forces acting on a rigid body.

Curves of Curvature; Asymptotic Lines.

16. The normals of a surface form a congruence. In any congruence the lines consecutive to a given congruence line do not

in general meet this line; but there is a determinate number of consecutive lines which do meet it; or, attending for the moment to only one of these, say the congruence line is met by a consecutive congruence-line. In particular, each normal is met by a consecutive normal; this again is met by a consecutive normal, and so on. That is, we have a singly infinite system of normals each meeting the consecutive normal, and so forming a torse; starting from different normals successively, we obtain a singly infinite system of such torses. But each normal is in fact met by two consecutive normals, and, using in the construction first the one and then the other of these, we obtain two singly infinite systems of torses each intersecting the given surface at right angles. In other words, if in place of the normal we consider the point on the surface, we obtain on the surface two singly infinite systems of curves such that for any curve of either system the normals at consecutive points intersect each other; moreover, for each normal the torses of the two systems intersect each other at right angles; and therefore for each point of the surface the curves of the two systems intersect each other at right angles. The two systems of curves are said to be the curves of curvature of the surface.

The normal is met by the two consecutive normals in two points which are the centres of curvature for the point on the surface; these lie either on the same side of the point or on opposite sides, and the surface has at the point in question like curvatures or opposite curvatures in the two cases respectively (see above, par. 4).

17. In immediate connexion with the curves of curvature we have the so-called asymptotic curves (Haupt-tangentenlinien). The tangent plane at a point of the surface cuts the surface in a curve having at that point a node. Thus we have at the point of the surface two directions of passage to a consecutive point, or, say, two elements of arc; and, passing along one of these to the consecutive point, and thence to a consecutive point, and so on, we obtain on the surface a curve. Starting successively from different points of the surface we thus obtain a singly infinite system of curves; or, using first one and then the other of the two directions, we obtain two singly infinite systems of curves, which are the curves above referred to. The two curves at any point are equally inclined to the two curves of curvature at that point, or—what is the same thing—the supplementary angles formed by the two asymptotic lines are bisected by the two curves of curvature. In the case of a quadric surface the asymptotic curves are the two systems of lines on the surface.

Geodetic Lines.

18. A geodetic line (or curve) is a shortest curve on a surface; more accurately, the element of arc between two consecutive points of a geodetic line is a shortest arc on the surface. We are thus led to the fundamental property that at each point of the curve the osculating plane of the curve passes through the normal of the surface; in other words, any two consecutive arcs PP', $P'P''$ are *in plano* with the normal at P'. Starting from a given point P on the surface, we have a singly infinite system of geodetics proceeding along the surface in the direction of the several tangent lines at the point P; and, if the direction PP' is given, the property gives a construction by successive elements of arc for the required geodetic line.

Considering the geodetic lines which proceed from a given point P of the surface, any particular geodetic line is or is not again intersected by the consecutive generating line; if it is thus intersected, the generating line is a shortest line on the surface up to, but not beyond, the point at which it is first intersected by the consecutive generating line; if it is not intersected, it continues a shortest line for the whole course.

In the analytical theory both of geodetic lines and of the curves of curvature, and in other parts of the theory of surfaces, it is very convenient to consider the rectangular co-ordinates x, y, z of a point of the surface as given functions of two independent parameters p, q; the form of these functions of course determines the surface, since by the elimination of p, q from the three equations we obtain the equation in the co-ordinates x, y, z. We have for the geodetic lines a differential equation of the second order between p and q; the general solution contains two arbitrary constants, and is thus capable of representing the geodetic line which can be drawn from a given point in a given direction on the surface. In the case of a quadric surface the solution involves hyperelliptic integrals of the first kind, depending on the square root of a sextic function.

Curvilinear Co-ordinates.

19. The expressions of the co-ordinates x, y, z in terms of p, q may contain a parameter r, and, if this is regarded as a given constant, these expressions will as before refer to a point on a given surface. But, if p, q, r are regarded as three independent parameters x, y, z will be the co-ordinates of a point in space, determined by means of the three parameters p, q, r; these parameters are said to be the curvilinear co-ordinates, or (in a generalized sense of the term) simply the co-ordinates of the point. We arrive otherwise at the notion by taking p, q, r each as a given function of x, y, z; say we have $p=f_1(x, y, z)$, $q=f_2(x, y, z)$, $r=f_3(x, y, z)$, which equations of course lead to expressions for p, q, r each as a function of x, y, z. The first equation determines a singly infinite set of surfaces: for any given value of p we have a surface; and similarly the second and third equations determine each a singly infinite set of surfaces. If, to fix the ideas, f_1, f_2, f_3 are taken to denote each a rational and integral function of x, y, z, then two surfaces of the same set will not intersect each other, and through a given point of space there will pass one surface of each set; that is, the point will be determined as a point of intersection of three surfaces belonging to the three sets respectively; moreover, the whole of space will be divided by the three sets of surfaces into a triply infinite system of elements, each of them being a parallelepiped.

Orthotomic Surfaces; Parallel Surfaces.

20. The three sets of surfaces may be such that the three surfaces through any point of space whatever intersect each other at right angles; and they are in this case said to be orthotomic. The term curvilinear co-ordinates was almost appropriated by Lamé, to whom this theory is chiefly due, to the case in question: assuming that the equations $p=f_1(x, y, z)$, $q=f_2(x, y, z)$, $r=f_3(x, y, z)$ refer to a system of orthotomic surfaces, we have in the restricted sense p, q, r as the curvilinear co-ordinates of the point.

An interesting special case is that of confocal quadric surfaces. The general equation of a surface confocal with the ellipsoid $\frac{x^2}{a^2}+\frac{y^2}{b^2}+\frac{z^2}{c^2}=1$ is $\frac{x^2}{a^2+\theta}+\frac{y^2}{b^2+\theta}+\frac{z^2}{c^2+\theta}=1$; and, if in this equation we consider x, y, z as given, we have for θ a cubic equation with three real roots p, q, r, and thus we have through the point three real surfaces, one an ellipsoid, one a hyperboloid of one sheet, and one a hyperboloid of two sheets.

21. The theory is connected with that of curves of curvature by Dupin's theorem. Thus in any system of orthotomic surfaces each surface of any one of the three sets is intersected by the surfaces of the other two sets in its curves of curvature.

22. No one of the three sets of surfaces is altogether arbitrary: in the equation $p=f_1(x, y, z)$, p is not an arbitrary function of x, y, z, but it must satisfy a certain partial differential equation of the third order. Assuming that p has this value, we have $q=f_2(x, y, z)$ and $r=f_3(x, y, z)$ determinate functions of x,y,z such that the three sets of surfaces form an orthotomic system.

23. Starting from a given surface, it has been seen (par. 16) that the normals along the curves of curvature form two systems of torses intersecting each other, and also the given surface, at right angles. But there are, intersecting the two systems of torses at right angles, not only the given surface, but a singly infinite system of surfaces. If at each point of the given surface we measure off along the normal one and the same distance at pleasure, then the locus of the points thus obtained is a surface cutting all the normals of the given surface at right angles, or, in other words, having the same normals as the given surface; and it is therefore a parallel surface to the given surface. Hence the singly infinite system of parallel surfaces and the two singly infinite systems of torses form together a set of orthotomic surfaces.

The Minimal Surface.

24. This is the surface of minimum area—more accurately, a surface such that, for any indefinitely small closed curve which can be drawn on it round any point, the area of the surface is less than it is for any other surface whatever through the closed curve. It at once follows that the surface at every point is concavo-convex; for, if at any point this was not the case, we could, by cutting the surface by a plane, describe round the point an indefinitely small closed plane curve, and the plane area within the closed curve would then be less than the area of the element of surface within the same curve. The condition leads to a partial differential equation of the second order for the determination of the minimal surface: considering z as a function of x, y, and writing as usual p, q, r, s, t for the first and the second differential coefficients of z in regard to x, y respectively, the equation (as first shown by Lagrange) is $(1+q^2)r-2pqs+(1+p^2)t=0$, or, as this may also be written, $\frac{d}{dy}\frac{q}{\sqrt{1+p^2+q^2}}+\frac{d}{dx}\frac{p}{\sqrt{1+p^2+q^2}}=0$. The general integral contains of course arbitrary functions, and, if we imagine these so determined that the surface may pass through a given closed curve, and if, moreover, there is but one minimal surface passing through that curve, we have the solution of the problem of finding the surface of minimum area within the same curve. The surface continued beyond the closed curve is a minimal surface, but it is not of necessity or in general a surface of minimum area for an arbitrary bounding curve not wholly included within the given closed curve. It is hardly necessary to remark that the plane is a minimal surface, and that, if the given closed curve is a plane curve, the plane is the proper solution; that is, the plane area within the given closed curve is less than the area for any other surface through the same curve. The given closed curve is not

of necessity a single curve: it may be, for instance, a skew polygon of four or more sides.

The partial differential equation was dealt with in a very remarkable manner by Riemann. From the second form given above it appears that we have $\frac{qdx-pdy}{\sqrt{1+p^2+q^2}}$ = a complete differential, or, putting this $=d\zeta$, we introduce into the solution a variable ζ, which combines with z in the forms $z\pm i\zeta$ $(i=\sqrt{-1})$. The boundary conditions have to be satisfied by the determination of the conjugate variables η, η' as functions of $z+i\zeta$, $z-i\zeta$, or, say, of Z, Z' respectively, and by writing S, S' to denote $x+iy$, $x-iy$ respectively. Riemann obtains finally two ordinary differential equations of the first order in S, S', η, η', Z, Z', and the results are completely worked out in some very interesting special cases. (A. CA.)

PART II.

We proceed to treat the differential geometry of surfaces, a study founded on the consideration of the expression of the lineal element in terms of two parameters, u, v,

$$ds^2=\mathrm{E}du^2+2\mathrm{F}dudv+\mathrm{G}dv^2,$$

u=const, v=const, being thus systems of curves traced on the surface. This method, which may be said to have been inaugurated by Gauss in his classical paper published in 1828, *Disquisitiones generales circa superficies curvas*, has the great advantage of dealing in the most natural way with all questions connected with geodetics, geodetic curvature, geodetic circles, &c.—in fact, all relations of lines on a surface which can be formulated without reference to anything external to the surface. All such relations when deduced for any particular surface can be at once generalized in their application, holding good for any other surface which has the same expression for its lineal element; *e.g.* relations involving great circles and small circles on a sphere furnish us with corresponding relations for geodetics and geodetic circles on any synclastic surface of constant specific curvature.

1. Gauss begins by introducing the conception of the integral curvature (*curvatura integra*) of any portion of a surface. This he defines to be the area of the corresponding portion of a sphere of unit radius, traced out by a radius drawn parallel to the normal at each point of the surface; *i.e.* it is $\iint ds/\mathrm{RR}'$ where R, R′ are the principal radii of curvature. The quotient obtained by dividing the integral curvature of a small portion of the surface round a point by the area of that portion, that is $1/\mathrm{RR}'$, he naturally calls the measure of curvature or the specific curvature at the point in question. He proceeds to establish his leading proposition, that this specific curvature at any point is expressible in terms of the E, F and G which enter into the equation for the lineal element, together with their differential coefficients with respect to the variables, u and v.

It is desirable to make clear the exact significance of this theorem. Of course, for any particular surface, the curvature can be expressed in an indefinite variety of ways. The speciality of the Gaussian expression is that it is deduced in such a manner as to hold good for all surfaces which have the same expression for the lineal element. The expression for the specific curvature, which is in general somewhat elaborate, assumes a very simple form when a system of geodetics and the system of their orthogonal trajectories are chosen for the parameter curves, the parameter u being made the length of the arc of the geodetic, measured from the curve, $u=0$ selected as the standard. If this be done the equation for the lineal element becomes $ds^2=du^2+\mathrm{P}^2dv^2$, and that for the specific curvature $(\mathrm{RR}^1)^{-1}=-\mathrm{P}^{-1}\,d^2\mathrm{P}/du^2$. By means of this last expression Gauss then proves that the integral curvature of a triangle formed by three geodetics on the surface can be expressed in terms of its angles, and is equal to $\mathrm{A}+\mathrm{B}+\mathrm{C}-\pi$.

This theorem may be more generally stated:—

The integral curvature of any portion of a surface $=2\pi-\Sigma di$ *round the contour of this portion*, where di denotes the angle of geodetic contingence of the boundary curve. The angle of geodetic contingence of a curve traced on a surface may be defined as the angle of intersection of two geodetic tangents drawn at the extremities of an element of arc, an angle which may be easily proved to be the same as the projection on the tangent plane of the ordinary angle of contingence. The geodetic curvature, ρ^{-1}, is thus equal to the ordinary curvature multiplied by cos ϕ, ϕ being the angle the osculating plane of the curve makes with the tangent plane.

Gauss's theorem may be established geometrically in the following simple manner: If we draw successive tangent planes along the curve, these will intersect in a system of lines, termed the *conjugate* tangents, forming a developable surface. If we unroll this developable then $di=d\theta-d\psi$, where di is the angle of geodetic contingence, $d\theta$ the angle between two consecutive conjugate tangents, ψ the angle the conjugate tangent makes with the curve. Therefore, as ψ returns to its original value when we integrate round the curve, we have $\Sigma di=\Sigma d\theta$. This equation holds for both the curve on the given surface and the representative curve on the sphere. But the tangent planes along these curves being always parallel, their successive intersections are so also; therefore $\Sigma d\theta$ is the same for both; consequently Σdi for the curve on the surface $=\Sigma di$ for the representative curve on the sphere. Hence integral curvature of curve of surface = area of representative curve on sphere,

$=2\pi-\Sigma di$ on sphere by spherical geometry,
$=2\pi-\Sigma di$ for curve on surface.

A useful expression for the geodetic curvature of one of the curves, v=const, can be obtained. If a curve receive a small displacement on any surface, so that the displacements of its two extremities are normal to the curve, it follows, from the calculus of variations, that the variation of the length of the curve $=\int\rho^{-1}\delta n ds$ where ρ^{-1} is the geodetic curvature, and δn the normal component of the displacement at each point. Applying this formula to one of the v curves, we find

$$\delta\int\mathrm{P}dv=\int(d\mathrm{P}/du)\delta u dv=\delta \text{ length of curve}=\int\rho^{-1}\,\delta u\mathrm{P}dv,$$

and as δu is the same for all points of the curve, $\rho^{-1}=\mathrm{P}^{-1}d\mathrm{P}/du$.

We can deduce immediately from this expression Gauss's value for the specific curvature. For applying his theorem to the quadrilateral formed by the curves u, u_1, v, v_1, and remembering that Σdi along a geodetic vanishes, we have

$$\begin{aligned}\iint(\mathrm{RR}')^{-1}\mathrm{P}dudv&=-\Sigma di \text{ for curve BC}-\Sigma di \text{ for curve DA},\\ &=-\Sigma\rho^{-1}ds \text{ for curve BC}+\Sigma\rho^{-1}ds \text{ for curve AD},\\ &=-\int\frac{1}{\mathrm{P}}\frac{d\mathrm{P}}{du}\mathrm{P}dv \text{ for curve BC}+\int\frac{1}{\mathrm{P}}\frac{d\mathrm{P}}{du}\mathrm{P}dv \text{ for curve AD},\\ &=-\int\left\{\left(\frac{d\mathrm{P}}{du}\right)_{u1}-\left(\frac{d\mathrm{P}}{du}\right)_{u}\right\}dv,\end{aligned}$$

therefore passing to the limit $\mathrm{P}/\mathrm{RR}'=-d^2\mathrm{P}/du^2$.

Gauss then proceeds to consider what the result will be if a surface be deformed in such a way that no lineal element is altered. It is easily seen that this involves that the angle at which two curves on the surface intersect is unaltered by this deformation; and since obviously geodetics remain geodetics, the angle of geodetic contingence and consequently the geodetic curvature are also unaltered. It therefore follows from his theorem that the integral curvature of any portion of a surface and the specific curvature at any point are unaltered by non-extensional deformation.

Geodetics and Geodetic Circles.

A geodetic and its fundamental properties are stated in part I., where it is also explained in that article within what range a geodetic possesses the property of being the shortest path between two of its points. The determination of the geodetics on a given surface depends upon the solution of a differential equation of the second order. The first integral of this equation, when it can be found for any given class of surfaces, gives us the characteristic property of the geodetics on such surfaces. The following are some of the well-known classes for which this integral has been obtained: (1) quadrics; (2) developable surfaces; (3) surfaces of revolution.

1. *Quadrics.*—Several mathematicians about the middle of the 19th century made a special study of the geometry of the lines of curvature and the geodetics on quadrics, and were rewarded by the discovery of many wonderfully simple and elegant analogies between their properties and those of a system of confocal conics and their tangents *in plano*. As explained above, the lines of curvature on a quadric are the systems of orthogonal curves formed by its intersection with the two systems of confocal quadrics. Joachimsthal showed that the interpretation of the first integral of the equation for geodetics on a central quadric is, that along a geodetic $p\mathrm{D}$=constant (C,) p denoting the perpendicular let fall from the centre on the tangent plane, and D the semidiameter drawn parallel to the element of the geodetic, the envelope of all geodetics having the same C being a line of curvature. In particular, all geodetics passing through one of the real umbilics (the four points where the indicatrix is a circle) have the same C.

Michael Roberts pointed out that it is an immediate consequence of the equation $p\mathrm{D}=\mathrm{C}$, that if two umbilics, A and B (selecting two not diametrically opposite), be joined by geodetics to any point P on a given line of curvature, they make equal angles with such line of curvature, and consequently that, as P moves along a line of curvature, either PA+PB or PA−PB remains constant. Or, conversely, that the locus of a point P on the surface, for which the sum or difference of the geodetic distances PA and PB is constant, is a line of curvature. It follows that if the ends of a string be fastened at the two umbilics of a central quadric, and a style move over the surface keeping the string always stretched, it will describe a line of curvature.

Another striking analogue is the following: As, *in plano*, if a variable point or an ellipse be joined to the two foci S and H, tan ½ PSH tan ½PHS=const, and for the hyperbola tan ½PSH/tan ½PHS=const, so for a line of curvature on a central quadric, if P be joined to two umbilics S and H by geodetics, either the product or the ratio of the tangents of ½PSH and ½PHS will be constant.

Chasles proved that if an ellipse be intersected in the point A by a confocal hyperbola, and from any point P on the hyperbola tangents PT, PT′ be drawn to the ellipse, then the difference of the arcs of the ellipse TA, T′A = the difference of the tangents PT, PT′; and subsequently Graves showed that if from any point P on the outer of two confocal ellipses tangents be drawn to the inner, then the excess of the sum of the tangents PT, PT′ over the intercepted arc TT′ is constant. Precisely the same theorems hold for a quadric replacing the confocals by lines of curvature and the rectilineal tangents by geodetic tangents. Hart still further developed the analogies with confocal conics, and established the following: If a geodetic polygon circumscribe a line of curvature, and all its vertices but one move on lines of curvature, this vertex will also describe a line of curvature, and when the lines of curvature all belong to the same system the perimeter of the polygon will be constant.

2. *Geodetics on Developable Surfaces.*—On these the geodetics are the curves which become right lines when the surface is unrolled into a plane. From this property a first integral can be immediately deduced.

3. *Geodetics on Surfaces of Revolution.*—In all such the geodetics are the curves given by the equation $r \sin \phi$=const, r being the perpendicular on the axis of revolution, ϕ the angle at which the curve crosses the meridian.

The general problem of the determination of geodetics on any surface may be advantageously treated in connexion with that of "parallel" curves. By "parallel" curves are meant curves whose geodetic distances from one another are constant—in other words, the orthogonal trajectories of a system of geodetics. In applying this method the determination of a system of parallel curves comes first, and the determination of the geodetics to which they are orthogonal follows as a deduction. If $\phi(u, v)$=const be a system of parallel curves, it is shown that ϕ must satisfy the partial differential equation

$$E\left(\frac{d\phi}{dv}\right)^2 - 2F\left(\frac{d\phi}{du}\right)\left(\frac{d\phi}{dv}\right) + G\left(\frac{d\phi}{dv}\right)^2 = EG - F^2.$$

If $\phi(u, v, a)$=const be a system of parallel curves satisfying this equation, then $d\phi/da$=const is proved to represent the orthogonal geodetics. The same method enables us to establish a result first arrived at by Jacobi, that whenever a first integral of the differential equation for geodetics can be found, the final integral is always reducible to quadratures. In this method ϕ corresponds to the characteristic function in the Hamiltonian dynamics, the geodetics being the paths of a particle confined to the surface when no extraneous forces are in action.

The expression for the lineal element on a quadric in elliptic co-ordinates suggested to Liouville the consideration of the class of surfaces for which this equation takes the more general form $ds^2 = (U-V)(U_1^2du^2 + V_1^2dv^2)$, where U, U_1 are functions of u, and V, V_1 functions of v, and shows that, for this class, the first integral of the equation of the parallels is immediately obtainable, and hence that of the corresponding geodetics. It is to be remarked that for this more general class of surfaces the theorems of Chasles and Graves given above will also hold good.

Geodetics on a surface corresponding to right lines on a plane, the question arises what curves on a surface should be considered to correspond to plane circles. There are two claimants for the position: first, the curves described by a point whose geodetic distance from a given point is constant; and, second, the curves of constant geodetic curvature.

On certain surfaces the curves which satisfy one of these conditions also satisfy the other, but in general the two curves must be carefully distinguished. The property involved in the second definition is more intrinsic, and we shall therefore, following Liouville, call the curves possessing it geodetic circles. It may be noted that geodetic circles, except on surfaces of constant specific curvature, do not return back upon themselves like circles *in plano*. As a particular instance, a geodetic on an ellipsoid (which is, of course, a geodetic circle of zero curvature), starting from an umbilic, when it returns again, as it does to that umbilic, makes a finite angle with its original starting position. As to the curve described by a point whose geodetic distance from a given centre is constant, Gauss showed from the fundamental property of a geodetic that this curve resembles the plane circle in being everywhere perpendicular to its radius. In the same way it holds that the curve described by a point the sum (or difference) of whose geodetic distances from two given points (foci) is constant, resembles the plane ellipse (or hyperbola) in the property that it bisects at every point the external (or internal) angle between the geodetic focal radii, and, as a consequence, that the curves on any surface answering to confocal ellipses and hyperbolas intersect at right angles. The equation for the lineal element enables us to discuss geodetic circles on surfaces of constant specific curvature; for we have seen that if we choose as parameters geodetics and their orthogonal trajectories, the equation becomes $ds^2 = du^2 + P^2du^2$; and since $(RR')^{-1} = -P^{-1}d^2P/du^2$, and here $(RR')^{-1} = \pm a^{-2}$, it follows $P = A \cos ua^{-1} + B \sin ua^{-1}$, or $P = A \cosh ua^{-1} + B \sinh ua^{-1}$, according as the surface is synclastic or anticlastic. If a geodetic circle (curvature k^{-1}) be chosen for the starting curve u=0, and if v be made the length of the arc OY, intercepted on this circle by the curve v=const (see fig. 1), then A and B can be proved to be independent of u and $P = \cos ua^{-1} + ak^{-1} \sin ua^{-1}$ for a synclastic surface, $P = \cosh ua^{-1} + ak^{-1} \sinh ua^{-1}$ for an anticlastic surface. It follows from the expression for the geodetic curvature $\rho^{-1} = P^{-1}dP/du$ that in both classes of surfaces all the other orthogonal curves u=const will be geodetic circles. It also appears that on a synclastic surface of constant specific curvature all the geodetics normal to a geodetic circle converge to a point on either side as on a sphere, and can be described with a stretched string taking either of these points as centre, the length of the string being $a \tan^{-1} ak^{-1}$ (see fig. 2). These normals will be all cut orthogonally by an equator, that is, by a geodetic circle of zero curvature.

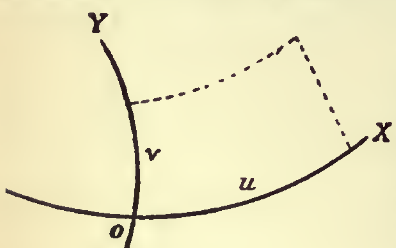


FIG. 1.

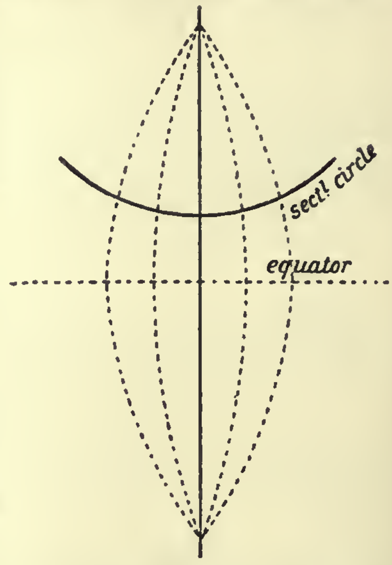

FIG. 2.

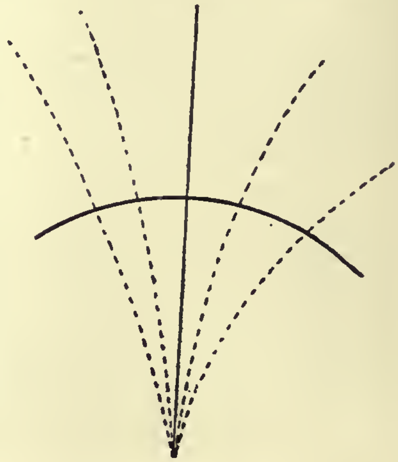

FIG. 3.

For anticlastic surfaces, however, we must distinguish two cases. If the curvature k^{-1} of the geodetic circle $> a^{-1}$ the geodetic normals meet in a point on the concave side of the geodetic circle, and can be described as on the synclastic by a stretched string, the length of the string being $a \tanh^{-1} ak^{-1}$, but in this case the geodetic normals have no equator (see fig. 3). If on the other hand the curvature of the geodetic circle be $< a^{-1}$ the normals do not meet on either side, but do possess an equator, and at this equator the geodetic normals come nearer together than they do anywhere else (see fig. 4).

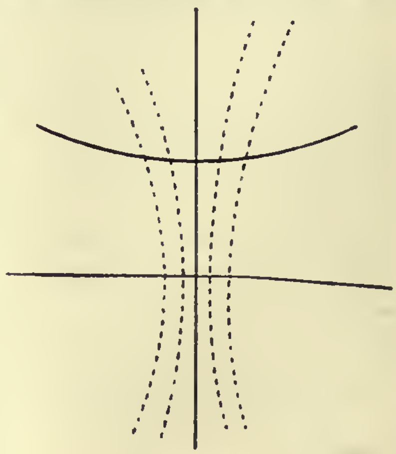

FIG. 4.

On a synclastic surface of constant specific curvature a^{-2} two near geodetics proceeding from a point always meet again at the geodetic distance πa; and more generally for any synclastic surface whose specific curvature at every point lies between the limits a^{-2} and b^{-2} two near geodetics proceeding from a point always meet again at a geodetic distance intermediate in value between πa and πb. On an anticlastic surface two near geodetics proceeding from a point never meet again.

Representation of Figures on a Surface by Corresponding Figures on a Plane; Theory of Maps.

The most valuable methods of effecting such representation are those in which small figures are identical in shape with the figures which they represent. This property is known to belong to the representation of a spherical surface by Mercator's method as well as to the representation by stereographic projection. The problem of effecting this "conformable" representation is easily seen to be equivalent to that of throwing the expression for the lineal element into what is known in the theory of heat conduction as the isothermal form $ds^2=\lambda(du^2+dv^2)$, for we have then only to choose for the representative point on the plane that whose rectangular co-ordinates are $x=u$, $y=v$. A curious investigation has been made by Beltrami—when is it possible to represent a surface on a plane in such a way that the geodetics on the surface shall correspond to the right lines on the plane (as, for example, holds true when a spherical surface is projected on a plane by lines through its centre)? He has proved that the only class of surface for which such representation is possible is the class of uniform specific curvature.

Just as the intrinsic properties of a synclastic surface of uniform specific curvature are reducible to those of a particular surface of this type, *i.e.* the sphere, so we can deal with an anticlastic surface of constant specific curvature, and reduce its properties to a particular anticlastic surface. A convenient surface to study for this purpose is that known as the *pseudosphere*, formed by the revolution of the tractrix (an involute of the catenary) round its base (see fig. 5). Its equations are $r=a\sin\phi$, $z=a(\cos\phi+\log\tan\frac{1}{2}\phi)$. This surface can be conformably represented as a plane map by choosing $x'=\omega$ where ω is the longitude of the point and $y'=a/\sin\phi$. It will then be found that $ds=ads'/y'$, where ds=lineal element on the surface, ds'=same on the map. It easily appears that geodetic circles on the surface are represented by circles on the map, the angle ψ at which these circles cut the base depending only upon the curvature of the geodetic circle, $\cos\psi$ being equal to ρ^{-1}. As a particular case it follows that the geodetics on the surface are represented by those special circles on the map whose centres lie on the base (see fig. 6). The geodetic distance between two points P and Q on the surface is represented by the logarithm of the anharmonic function AP'BQ', where P'Q' are the representing points on the map, A B the points in which the circle on the map which passes through P' and Q' and has its centre on the base cuts the base. The perimeter (l) of a geodetic circle of curvature ρ^{-1} turns out to be $2\pi a\rho/\sqrt{(a^2-\rho^2)}$, and its area $(l\rho^{-1}-2\pi)a^2$. The geometry of coaxal circles *in plano* accordingly enables us to demonstrate anew by means of the pseudosphere the properties which we have shown to hold good in all anticlastic surfaces of constant curvature. Thus the system of geodetics cutting orthogonally a geodetic circle C will be represented on the map by circles having their centres on the base, and cutting a given circle C' orthogonally, *i.e.* by a coaxal system of circles. We know that the other orthogonal trajectories of this last system are another coaxal system, and therefore, going back to the pseudosphere, we learn that if a system of geodetics be drawn normal to a geodetic circle, all the orthogonals to this system are geodetic circles. It is to be noted that while every point on the surface has its representative on the map, the converse does not hold. It is only points lying above the line $y'=a$ which have their prototypes on the surface, the portion of the plane below this line not answering to any real part of the surface. If we take any curve C' on the map crossing this line, the part of the curve above this line has as its prototype a curve on the surface. When C' reaches this line, C reaches the circular base of the pseudosphere, and there terminates abruptly. The distinction between the two cases of a geodetic circle with curvature greater and one with curvature less than a^{-1} also comes out clearly. For if curvature of C$>a^{-1}$ the map circle C' lies entirely above the base, and the coaxal system cutting C' orthogonally passes through a real point; therefore C has a centre. If curvature of C$<a^{-1}$ the map circle C' intersects the base, the coaxal system cutting C' orthogonally does not intersect in a real point, and C has accordingly no centre. It is of interest to examine in what way a pseudosphere differs from a plane as regards the behaviour of parallel lines. If on a plane a geodetic AB (*i.e.* a right line) be taken, and another geodetic constantly pass through a point P and revolve round P, it will always meet AB in the point except in the particular position. On the pseudosphere, if we carry out the corresponding construction, the position of the non-intersecting geodetic is not unique, but all geodetics drawn within a certain angle fail to meet the geodetic AB.

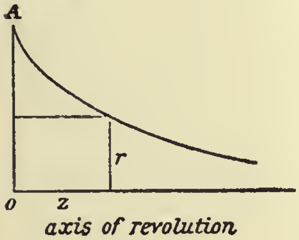

FIG. 5.

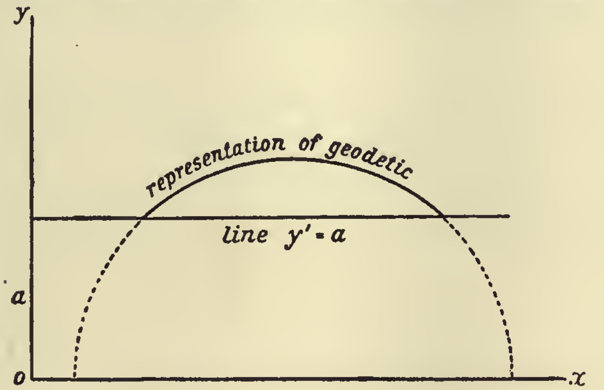

FIG. 6.

Minimal Surfaces.

From the definition given in part I. readily follows the well-known property of these surfaces—that the two principal curvatures are at every point of such a surface equal and opposite. For familiar instances of the class we have the surface formed by the revolution of a catenary round its base called by French mathematicians the alysséide, and the right conoid, $z=a\tan^{-1}(y/x)$, formed by the successive edges of the steps of a spiral staircase. Monge succeeded in expressing the co-ordinates of the most general minimal surface in two parameters, and in a form in which the variables are separated. The separation of the variables in the expression signifies that every minimal surface belongs to the class of surfaces which can be generated by a movement of translation of a curve. Enneper has thrown the expression for the co-ordinates into the following convenient forms:—

$$x=\tfrac{1}{2}\int(1-u^2)f(u)du+\tfrac{1}{2}\int(1-v^2)\phi(v)dv,$$
$$y=\tfrac{1}{2}i\int(1+u^2)f(u)du-\tfrac{1}{2}i\int(1+v^2)\phi(v)dv,$$
$$z=\int uf(u)du+\int v\phi(v)dv.$$

It is noteworthy that the expression for the lineal element on a minimal surface assumes the isothermal form $ds^2=\lambda(du^2+dv^2)$—(1) when the curves u=const, v=const are so chosen as to be the lines of curvature; and (2) when they are chosen to be the lines in which the surface is intersected by a system of parallel planes and the orthogonal trajectories of these lines. It is easily proved that a minimal surface possesses the property of being conformable to its spherical representation. For since the indicatrix at every point is a rectangular hyperbola, the angle between the elements of two intersecting curves=angle between their conjugate tangents; but this=angle between conjugate tangents to representative curves on sphere=angle between these curves themselves.

The problem of finding a minimal surface to pass through a given curve in space, known as Plateau's problem, possesses an exceptional interest from the circumstance that it can be always exhibited to the eye in the following way by an actual physical experiment. Dip a wire having the form of the given curve in a soap-bubble solution, and the film adhering to the wire when it is withdrawn is the surface required. This is evident, since from the theory of surface-tension we know that a very thin film must assume that form for which the area of its surface is the least possible. The same theory also furnishes us with an elementary proof of the characteristic property that the sum of the curvatures is everywhere zero, inasmuch as the normal pressure on the film, here zero, is known to be proportional to the surface-tension multiplied by the sum of the curvatures.

Riemann, adopting a method depending upon the use of the complex variable, has succeeded in solving Plateau's problem for several interesting cases, *e.g.* 1° when the contour consists of three infinite right lines; 2° when it consists of a gauche quadrilateral; and 3° when it consists of any two circles situated in parallel planes. (For Lie's investigations in this domain, see GROUPS, THEORY OF.)

Non-extensional Deformation.

We have already explained what is meant by this term. It is a subject to which much study has been devoted, connecting itself, as it does, with the work of Gauss in pure geometry on the one hand and with the theory of elasticity on the other. Several questions have been opened up: (1) What are the conditions which must be fulfilled by two surfaces such that one can be "deformed" so as to fit on the other? (2) What instances have we of known surfaces applicable to one another? (3) What surfaces are applicable to themselves? (4) In regard to infinitely small deformations, what are the differential equations which must be satisfied by the displacements? (5) Under what circumstances can a surface not be deformed? Can a closed surface ever be deformed?

1. Of course if two surfaces are applicable we must be able to get two systems of parameter curves u=const, v=const, on the first

surface, and two systems on the second, such that the equation for the lineal element, when referred to these, may have an identical form for the two surfaces. The problem is now to select these corresponding systems. We may conveniently take for the co-ordinate u the specific curvature on each surface, and choose for v the function du/dn which denotes the rate of increase of u along a direction normal to the curve u=const. Then, since at corresponding points both u and v will be the same for one surface as for the other, if the surfaces are applicable, E, F and G, in the equation $ds^2=\mathrm{E}du^2+2\mathrm{F}dudv+\mathrm{G}dv^2$, must be identical for the two surfaces. Clerk Maxwell has put the geometrical relation which exists between two applicable surfaces in the following way: If we take any two corresponding points P and P′ on two such surfaces, it is always possible to draw two elements through P parallel to conjugate semi-diameters of the indicatrix at P, such that the corresponding elements through P′ shall be parallel to conjugate semi-diameters of the indicatrix at P′. The curves made up of all these elements will divide the two surfaces into small parallelograms, the four parallelograms having P as common vertex being identical in size and shape with the four having P′ as vertex. Maxwell regards the surfaces as made up in the limit of these small parallelograms. Now, in order to render these surfaces ready for application, the first step would be to alter the angle between two of the planes of the parallelograms at P, so as to make it equal to that between the corresponding planes at P′. If this be done it is readily seen that all the angles between the other planes at P and P′, and at all other corresponding points, will become equal also. The curves which thus belong to the conjugate systems common to the two surfaces may be regarded as *lines of bending*.

2. Any surface of uniform specific curvature, whether positive or negative, is applicable to another surface of the same uniform specific curvature in an infinite variety of ways. For if we arbitrarily choose two points, O and O′, one on each surface, and two elements, one through each point, we can apply the surfaces, making O and O′ corresponding points and the elements corresponding elements. This follows from the form of the equation of the lineal element, which is for synclastic surfaces $ds^2=du^2+a^2\sin^2(ua^{-1})dv^2$, and for anticlastic, $ds^2=du^2+a^2\sinh^2(ua^{-1})dv^2$, and is therefore identical for the two surfaces in question. Again, a ruled surface may evidently be deformed by first rotating round a generator, the portion of the surface lying to one side of this generator, then round the consecutive generator, the portion of the surface lying beyond this again, and so on. It is clear that in such deformation the rectilinear generators in the old surface remain the rectilinear generators in the new; but it is interesting to note that two ruled surfaces can be constructed which shall be applicable, yet so that the generators will not correspond. For, deform a hyperboloid of one sheet in the manner described, turning the portions of the surface round the consecutive generators of one system, and then deform the hyperboloid, using the generators of the other system. The two surfaces so obtained are, of course, applicable to one another, yet so that their generators do not now correspond. Conversely Bonnet has shown that, whenever two ruled surfaces are thus applicable, without correspondence of generators, they must be both applicable to the same hyperboloid of one sheet. The alysséide is a good example of a surface of revolution applicable to a ruled surface, in this case the right circular conoid, the generators of the conoid coinciding with the meridians of the alysséide.

3. As instances of surfaces applicable to themselves, we may take surfaces of uniform specific curvature, as obviously follows from the reasoning already given; also surfaces of revolution, inasmuch as any such surface can be turned round its axis and still fit upon its old position. Again, helicoidal surfaces possess this property. A helicoidal surface means that traced out by a rigid wire, which is given a screw motion round a fixed axis, or, which comes to the same thing, the surface made up of a system of helices starting from the points of a given curve, all having the same axis and the same interval between the successive threads. The applicability of such a surface to itself, if given a screw motion round the axis, is evident from the law of its formation.

4. The possible small variations ξ, η, ζ of the points of a surface when it is subject to a small inextensional deformation are conditioned by the equation $dxd\xi+dyd\eta+dzd\zeta=0$, or making x and y the independent variables,

$$dx^2\left(\frac{d\xi}{dx}+p\frac{d\zeta}{dx}\right)+dxdy\left(\frac{d\xi}{dy}+\frac{d\eta}{dx}+p\frac{d\zeta}{dy}+q\frac{d\zeta}{dx}\right)+dy^2\left(\frac{d\eta}{dy}+q\frac{d\zeta}{dy}\right)=0.$$

From this it follows that the three equations must separately hold

$$\frac{d\xi}{dx}+p\frac{d\zeta}{dx}=0,\ \frac{d\xi}{dy}+\frac{d\eta}{dx}+p\frac{d\zeta}{dy}+q\frac{d\zeta}{dx}=0,\ \frac{d\eta}{dy}+q\frac{d\zeta}{dy}=0.$$

Accordingly, the determination of a possible small deformation of a given surface is reduced to the analytical problem of finding three functions ξ, η, ζ of the variables x and y to satisfy these equations. Changing the co-ordinates to α and β where α=const, β=const, are the curves of inflexion on the surface, the solution of the equations can be shown to depend upon that of the equation $d^2w/d\alpha d\beta=\lambda w$, where λ is a function of α and β depending on the form of the surface. The last equation can be integrated, and the possible deformation determined in the case of a spherical surface, or of any surface of uniform specific curvature. It is easily shown that if we have determined the displacements for any surface S we can do so for any surface obtained from S by a linear transformation of the variables.

For let

$$x'=a_1x=b_1y+c_1z+d_1,\ y=a_2x+b_2y+c_2z+d_2,$$
$$z'=a_3x+b_3y+c_3z+d_3,$$

then the displacements

$$\xi'=\mathrm{A}_1\xi+\mathrm{B}_1\eta+\mathrm{C}_1\zeta,\ \eta'=\mathrm{A}_2\xi+\mathrm{B}_2\eta+\mathrm{C}_2\zeta,\ \zeta'=\mathrm{A}_3\xi+\mathrm{B}_3\eta+\mathrm{C}_3\zeta,$$

where A_1 B_1, &c., are the minors of the determinant $[a_1\ b_2\ c_3]$, will evidently satisfy the equation

$$dx'd\xi'+dy'd\eta'+dz'd\zeta'=0.$$

Accordingly the known solution for a sphere furnishes us with a solution for any quadric. Moutard has pointed out a curious connexion between the problem of small deformation and that of the applicability of two finitely different surfaces.

For if $dxd\xi+dyd\eta+dzd\zeta=0$, it follows that if k be any constant,

$$\{d(x+k\xi)\}^2+\{d(y+k\eta)\}^2+\{d(z+k\zeta)\}^2$$
$$=\{d(x-k\xi)\}^2+\{d(y-k\eta)\}^2+\{d(z-k\zeta)\}^2.$$

Consequently, if we take two surfaces such that for the first

$$\mathrm{X}=x+k\xi,\ \mathrm{Y}=y+k\eta,\ \mathrm{Z}=z+k\zeta,$$

and for the second

$$\mathrm{X}'=x-k\xi,\ \mathrm{Y}'=y-k\eta,\ \mathrm{Z}'=z-k\zeta,$$

then

$$d\mathrm{X}^2+d\mathrm{Y}^2+d\mathrm{Z}^2=d\mathrm{X}'^2+d\mathrm{Y}'^2=d\mathrm{Z}'^2,$$

and therefore the new surfaces are applicable.

5. Jellett and Clerk Maxwell have shown by different methods that, if a curve on a surface be held fixed, there can be no small deformation, except this curve be a curve of inflexion. This may be also proved thus: There can be no displacement of the tangent planes along the fixed curve, for, at any point of the curve the geodetic curvature cannot alter; but in present case the ordinary curvature of the curve is also fixed, therefore their ratio is constant, so that $\delta\cos\theta=-\sin\theta\delta\theta=0$, where θ is the angle which the osculating plane makes with the tangent plane; therefore unless $\sin\theta=0$, as it is along a curve of inflexion, $\delta\theta=0$, and therefore the tangent plane at each point is unaltered. Hence it can be shown that along the given curve not only ξ, η, ζ vanish, but also their differential coefficients of all orders, and therefore no displacement is possible.

The question has been much discussed: Can a closed synclastic surface be deformed? There seems to be a prevalent opinion amongst mathematicians that such deformation is always impossible, but we do not think any unimpeachable demonstration of this has yet been given. It is certain that a complete spherical surface does not admit of inextensive deformation, for if it did it would follow from Gauss's theorem that the new surface would have a uniform specific curvature. Now, it is not difficult to prove that the only closed surface possessing this property is the sphere itself, provided that the surfaces in question be such that all their tangent planes lie entirely outside them. We can then, by the method of linear transformation already given, extend the theorem of the impossibility of deformation to any ellipsoid.

The theorem that a sphere is the only closed surface of constant specific curvature may, we suggest, be established by means of the following two propositions, which hold for integration on any closed surface, p being the perpendicular from the origin on the tangent plane:—

$$\iint(1/\mathrm{R}+1/\mathrm{R}')\,d\mathrm{S}=2\iint p\,d\mathrm{S}/\mathrm{RR}' \qquad (1)$$

$$2\iint d\mathrm{S}=\iint p(1/\mathrm{R}+1/\mathrm{R}')d\mathrm{S}. \qquad (2)$$

Now multiply both sides of the first equation by the constant $\sqrt{\mathrm{RR}'}$, and subtract the second, and we get:—

$$\iint\{(\mathrm{R}'/\mathrm{R})^{\frac{1}{2}}-(\mathrm{R}/\mathrm{R}')^{\frac{1}{2}}\}^2d\mathrm{S}+\iint p(1/\mathrm{R}^{\frac{1}{2}}-1/\mathrm{R}'^{\frac{1}{2}})^2d\mathrm{S}=0$$

which is impossible unless R′=R everywhere, since in accordance with the proviso p is everywhere positive.

Theorems (1) and (2) are deduced by Jellett by means of the calculus of variations in his treatise on that subject. They may also be very simply proved thus: Draw normals to the surface along the contours of the small squares formed by lines of curvature, and let these meet successive parallel surfaces at distances dn, then the volume bounded by two parallel surfaces

$$=\iint\left(d\mathrm{S}\int_0^n dn(1+n/\mathrm{R})(1+n/\mathrm{R}')\right)$$
$$=\iint d\mathrm{S}(n+\tfrac{1}{2}n^2(1/\mathrm{R}+1/\mathrm{R}')+\tfrac{1}{3}n^3/\mathrm{RR}');$$

but taking origin inside, the perpendiculars let fall from O on a tangent plane to the outer surface $=p+n$ on account of the parallelism of the surfaces. Also $d\mathrm{S}$ for outer surface $=d\mathrm{S}(1+n/\mathrm{R})(1+n/\mathrm{R}')$; therefore volume in question

$$=\tfrac{1}{3}\iint(p+n)(1+n/\mathrm{R})(1+n/\mathrm{R}')d\mathrm{S}-\tfrac{1}{3}\iint p\,d\mathrm{S}$$
$$=\tfrac{1}{3}n\iint\left(1+\frac{p}{\mathrm{R}}+\frac{p}{\mathrm{R}'}\right)d\mathrm{S}+\tfrac{1}{3}n^2\iint\left(\frac{p}{\mathrm{RR}'}+\frac{1}{\mathrm{R}}+\frac{1}{\mathrm{R}'}\right)d\mathrm{S}+\tfrac{1}{3}n^3\iint\frac{1}{\mathrm{RR}'}d\mathrm{S}.$$

Hence equating coefficients of the powers of n—

$$\iint p\,(1/R + 1/R')dS = 2\iint dS,$$

and $$\iint 2pdS/RR' = \iint (1/R + 1/R')dS.$$

References to the original memoirs will be found in Salmon's *Analytical Geometry of Three Dimensions*, Frost's *Solid Geometry* and, more completely, in Darboux's *Leçons sur la théorie générale des surfaces.* (J. Pu.; F. Pu.)

SURGE, in meteorology, an irregular fluctuation of the barometer, extending over a long period (*e.g.* a month), in contradistinction to the shorter fluctuations, covering two or three days, caused by alternating conditions of high and low pressure. The cause of surges is not understood.

SURGERY (Fr. *chirurgie*, from Gr. *χειρουργία*, *i.e.* handwork), the profession and art of the surgeon (*chirurgien*), connected specially with the cure of diseases or injuries by operative manual and instrumental treatment.

History.—Surgery in all countries is as old as human needs. A certain skill in the stanching of blood, the extraction of arrows, the binding up of wounds, the supporting of broken limbs by splints, and the like, together with an instinctive reliance on the healing power of the tissues, has been common to men everywhere. In both branches of the Indo-European stock surgical practice (as well as medical) reached a high degree of perfection at a very early period. It is a matter of controversy whether the Greeks got their medicine (or any of it) from the Hindus (through the medium of the Egyptian priesthood), or whether the Hindus owed that high degree of medical and surgical knowledge and skill which is reflected in Charaka (1st century A.D.) and Suśruta (2nd century) (commentators of uncertain date on the Yajur-Veda) to their contact with Western civilization after the campaigns of Alexander. The evidence in favour of the former view is ably stated by Wise in the Introduction to his *History of Medicine Among the Asiatics* (London, 1868). The correspondence between the *Suśruta* and the *Hippocratic Collection* is closest in the sections relating to the ethics of medical practice; the description, also, of lithotomy in the former agrees almost exactly with the account of the Alexandrian practice as given by Celsus. But there are certainly some dexterous operations described in Suśruta (such as the rhinoplastic) which were of native invention; the elaborate and lofty ethical code appears to be of pure Brahmanical origin; and the copious materia medica (which included arsenic, mercury, zinc, and many other substances of permanent value) does not contain a single article of foreign source. There is evidence also (in Arrian, Strabo and other writers) that the East enjoyed a proverbial reputation for medical and surgical wisdom at the time of Alexander's invasion. We may give the first place, then, to the Eastern branch of the Indo-European stock in a sketch of the rise of surgery, leaving as insoluble the question of the date of the Sanskrit compendiums or compilations which pass under the names of two representative persons, Charaka and Suśruta (the dates assigned to these ranging as widely as 500 years on each side of the Christian era).

Hindu.

The *Suśruta* speaks throughout of a single class of practitioners who undertook both surgical and medical cases. Nor were there any fixed degrees or orders of skill within the profession; even lithotomy, which at Alexandria was assigned to specialists, was to be undertaken by any one, the leave of the raja having been first obtained. The only distinction recognized between medicine and surgery was in the inferior order of barbers, nail-trimmers, ear-borers, tooth-drawers and phlebotomists, who were outside the Brahmanical caste.

Suśruta describes more than one hundred surgical instruments, made of steel. They should have good handles and firm joints, be well polished, and sharp enough to divide a hair; they should be perfectly clean, and kept in flannel in a wooden box. They included various shapes of scalpels, bistouries, lancets, scarifiers, saws, bone-nippers, scissors, trocars and needles. There were also blunt hooks, loops, probes (including a caustic-holder), directors, sounds, scoops and forceps (for polypi, &c.), as well as catheters, syringes, a rectal speculum and bougies. There were fourteen varieties of bandage. The favourite form of splint was made of thin slips of bamboo bound together with string and cut to the length required. Wise says that he had frequently used "this admirable splint," particularly for fractures of the thigh, humerus, radius and ulna, and it was subsequently adopted in the English army under the name of the "patent rattan-cane splint."

Fractures were diagnosed, among other signs, by crepitus. Dislocations were elaborately classified, and the differential diagnosis given; the treatment was by traction and countertraction, circumduction and other dexterous manipulation. Wounds were divided into incised, punctured, lacerated, contused, &c. Cuts of the head and face were sewed. Skill in extracting foreign bodies was carried to a great height, the magnet being used for iron particles under certain specified circumstances. Inflammations were treated by the usual antiphlogistic regimen and appliances; venesection was practised at several other points besides the bend of the elbow; leeches were more often resorted to than the lancet; cupping also was in general use. Poulticing, fomenting and the like were done as at present. Amputation was done now and then, notwithstanding the want of a good control over the haemorrhage; boiling oil was applied to the stump, with pressure by means of a cup-formed bandage, pitch being sometimes added. Tumours and enlarged lymphatic glands were cut out, and an arsenical salve applied to the raw surfaces to prevent recurrence. Abdominal dropsy and hydrocele were treated by tapping with a trocar; and varieties of hernia were understood, omental hernia being removed by operation on the scrotum. Aneurisms were known, but not treated; the use of the ligature on the continuity of an artery, as well as on the cut end of it in a flap, is the one thing that a modern surgeon will miss somewhat noticeably in the ancient surgery of the Hindus; and the reason of their backwardness in that matter was doubtless their want of familiarity with the course of the arteries and with the arterial circulation. Besides the operation already mentioned, the abdomen was opened by a short incision below the umbilicus slightly to the left of the middle line for the purpose of removing intestinal concretions or other obstruction (laparotomy). Only a small segment of the bowel was exposed at one time; the concretion when found was removed, the intestine stitched together again, anointed with ghee and honey, and returned into the cavity. Lithotomy was practised, without the staff. There was a plastic operation for the restoration of the nose, the skin being taken from the cheek adjoining, and the vascularity kept up by a bridge of tissue. The ophthalmic surgery included extraction of cataract. Obstetric operations were various, including caesarean section and crushing the foetus.

The medication and constitutional treatment in surgical cases were in keeping with the general care and elaborateness of their practice, and with the copiousness of their materia medica. Ointments and other external applications had usually a basis of ghee (or clarified butter), and contained, among other things, such metals as arsenic, zinc, copper, mercury and sulphate of iron. For every emergency and every known form of disease there were elaborate and minute directions in the śāstras, which were taught by the physician-priests to the young aspirants. Book learning was considered of no use without experience and manual skill in operations; the different surgical operations were shown to the student upon wax spread on a board, on gourds, cucumbers and other soft fruits; tapping and puncturing were practised on a leathern bag filled with water or soft mud; scarifications and bleeding on the fresh hides of animals from which the hair had been removed; puncturing and lancing upon the hollow stalks of water-lilies or the vessels of dead animals; bandaging was practised on flexible models of the human body; sutures on leather and cloth; the plastic operations on dead animals; and the application of caustics and cauteries on living animals. A knowledge of anatomy was held to be necessary, but it does not appear that it was systematically acquired by dissection. Superstitions and theurgic ideas were diligently kept up so as to impress the vulgar. The whole body of teaching, itself the slow growth of much close observation and profound thinking during the vigorous period of Indo-Aryan progress, was given out in later times as a revelation from heaven, and as resting upon an absolute authority. Pathological principles were not wanting, but they were derived from a purely arbitrary or conventional physiology (wind, bile and phlegm); and the whole elaborate fabric of rules and directions, great though its utility must have been for many generations, was without the quickening power of reason and freedom, and became inevitably stiff and decrepit.

Chinese.

The Chinese appear to have been far behind the Hindus in their knowledge of medicine and surgery, notwithstanding that China profited at the same time as Tibet by the missionary propagation of Buddhism. Surgery in particular had hardly developed among them beyond the merest rudiments, owing to their religious respect for dead bodies and their unwillingness to draw blood or otherwise interfere with the living structure. Their anatomy and physiology have been from the earliest times unusually fanciful, and their surgical practice has consisted almost entirely of external applications. Tumours and boils were treated by scarifications or incisions. The distinctive Chinese surgical invention is *acupuncture*, or the insertion of fine needles, of hardened silver or gold, for an inch or more (with a twisting motion) into the seats of pain or inflammation. Wise says that "the needle is allowed to remain in that part several minutes, or in some cases of neuralgia for days, with great advantage"; rheumatism and chronic gout were among the localized pains so treated. There are 367 points specified where needles may be inserted without injuring great vessels and vital organs.

Egyptian.

Cupping-vessels made of cow-horn have been found in ancient Egyptian tombs. On monuments and the walls of temples are figures of patients bandaged, or undergoing operation at the hands of surgeons. In museum collections of Egyptian antiquities there are lancets, forceps, knives, probes, scissors, &c. Ebers interprets a passage in the papyrus discovered by him as relating to the operation of cataract. Surgical instruments for the ear are figured, and artificial teeth have been found in mummies. Mummies have also been found with well-set fractures. Herodotus describes Egypt, notwithstanding its fine climate, as being full of medical practitioners, who were all "specialists." The ophthalmic surgeons were celebrated, and practised at the court of Cyrus.

Greek.

Greek Surgery.—As in the case of the Sanskrit medical writings, the earliest Greek compendiums on surgery bear witness to a long organic growth of knowledge and skill through many generations. In the Homeric picture of society the surgery is that of the battlefield, and it is of the most meagre kind. Achilles is concerned about the restoration to health of Machaon for the reason that his skill in cutting out darts and applying salves to wounds was not the least valuable service that a hero could render to the Greek host. Machaon probably represents an amateur, whose taste had led him, as it did Melampus, to converse with centaurs and to glean some of their traditional wisdom. Between that primitive state of civilization and the date of the first Greek treatises there had been a long interval of gradual progress.

Hippocratic Surgery.

The surgery of the *Hippocratic Collection* (age of Pericles) bears every evidence of finish and elaboration. The two treatises on fractures and on dislocations respectively are hardly surpassed in some ways by the writings of the present mechanical age. Of the four dislocations of the shoulder the displacement downwards into the axilla is given as the only one at all common. The two most usual dislocations of the femur were backwards on to the dorsum ilii and forwards on to the obturator region. Fractures of the spinous processes of the vertebrae are described, and caution advised against trusting those who would magnify that injury into fracture of the spine itself. Tubercles (φύματα) are given as one of the causes of spinal curvature, an anticipation of Pott's diagnosis. In all matters of treatment there was the same fertility of resource as in the Hindu practice; the most noteworthy point is that shortening was by many regarded as inevitable after simple fracture of the femur. Fractures and dislocations were the most complete chapters of the Hippocratic surgery; the whole doctrine and practical art of them had arisen (like sculpture) with no help from dissection, and obviously owed its excellence to the opportunities of the palaestra. The next most elaborate chapter is that on wounds and injuries of the head, which refers them to a minute subdivision, and includes the depressed fracture and the *contrecoup*. Trephining was the measure most commonly resorted to, even where there was no compression. Numerous forms of wounds and injuries of other parts are specified. Ruptures, piles, rectal polypi, fistula in ano and prolapsus ani were among the other conditions treated. The amputation or excision of tumours does not appear to have been undertaken so freely as in Hindu surgical practice; nor was lithotomy performed except by a specially expert person now and then. The diagnosis of empyema was known, and the treatment of it was by an incision in the intercostal space and evacuation of the pus. Among their instruments were forceps, probes, directors, syringes, rectal speculum, catheter and various kinds of cautery.

Alexandrian Period.

Between the Hippocratic era and the founding of the school of Alexandria (about 300 B.C.) there is nothing of surgical progress to dwell upon. The Alexandrian epoch stands out prominently by reason of the enthusiastic cultivation of human anatomy—there are allegations also of vivisection—at the hands of Herophilus (335–280 B.C.) and Erasistratus (280 B.C.). The substance of this movement appears to have been precision of diagnosis (not unattended with pedantic minuteness), boldness of operative procedure, subdivision of practice into a number of specialities, but hardly a single addition to the stock of physiological or pathological ideas, or even to the traditional wisdom of the Hippocratic time. "The surgeons of the Alexandrian school were all distinguished by the nicety and complexity of their dressings and bandagings, of which they invented a great variety." Herophilus boldly used the knife even on internal organs such as the liver and spleen, which latter he regarded "as of little consequence in the animal economy." He treated retention of urine by a particular kind of catheter, which long bore his name. Lithotomy was much practised by a few specialists, and one of them (Ammonius Lithotomos, 287 B.C.) is said to have used an instrument for breaking the stone in the bladder into several pieces when it was too large to remove whole. A sinister story of the time is that concerning Antiochus, son of Alexander, king of Syria (150 B.C.), who was done to death by the lithotomists when he was ten years old, under the pretence that he had stone in the bladder, the instigator of the crime being his guardian and supplanter Diodotus.

Celsus.

The treatise of Celsus, *De re medica* (reign of Augustus), reflects the state of surgery in the ancient world for a period of several centuries: it is the best record of the Alexandrian practice itself, and it may be taken to stand for the Roman practice of the period following. Great jealousy of Greek medicine and surgery was expressed by many of the Romans of the republic, notably by Cato the Elder (234–149 B.C.), who himself practised on his estate according to the native traditions. His medical observations are given in *De re rustica*. In reducing dislocations he made use of the following incantation: "Huat hanat ista pista sista damiato damnaustra." The first Greek surgeon who established himself in Rome is said to have been Archagathus, whose fondness for the knife and cautery at length led to his expulsion by the populace. It was in the person of Asclepiades, the contemporary and friend of Cicero, that the Hellenic medical practice acquired a permanent footing in Rome. He confined his practice mostly to medicine, but he is credited with practising the operation of tracheotomy. He is one of those whom Tertullian quotes as practising vivisections for the gratification of their curiosity (*De anima*, 15). The next figure in the surgical history is Celsus, who devotes the 7th and 8th books of his *De re medica* exclusively to surgery. There is not much in these beyond the precepts of the Brahmanical śāstras and the maxims and rules of Greek surgery. Plastic operations for the restoration of the nose, lips and ears are described at some length, as well as the treatment of hernia by taxis and operation; in the latter it was recommended to apply the actual cautery to the canal after the hernia had been returned. The celebrated description of lithotomy is that of the operation as practised long before in India and at Alexandria. The treatment of sinuses in various regions is dwelt upon, and in the case of sinuses of the thoracic wall resection of the rib is mentioned. Trephining has the same prominent place assigned to it as in the Greek surgery. The resources of contemporary surgery may be estimated by the fact that subcutaneous urethrotomy was practised when the urethra was blocked by a calculus. Amputation of an extremity is described in detail for the first time in surgical literature. Mention is made of a variety of ophthalmic operations, which were done by specialists after the Alexandrian fashion.

Galen.

Galen's practice of surgery was mostly in the early part of his career (b. A.D. 130), and there is little of special surgical interest in his writings, great as their importance is for anatomy, physiology and the general doctrines of disease. Among the operations credited to him are resection of a portion of the sternum for caries and ligature of the temporal artery. It may be assumed that surgical practice was in a flourishing condition all through the period of the empire from the accounts preserved by Oribasius of the great surgeons Antyllus, Leonides, Rufus and Heliodorus. Antyllus (A.D. 300) is claimed by Häser as one of the greatest of the world's surgeons; he had an operation for aneurism (tying the artery above and below the sac, and evacuating its contents), for cataract, for the cure of stammering; and he treated contractures by something like tenotomy. Rufus and Heliodorus are said to have practised torsion for the arrest of haemorrhage; but in later periods both that and the ligature appear to have given way to the actual cautery. Häser speaks of the operation for scrotal hernia attributed to Heliodorus as "a brilliant example of the surgical skill during the empire." The same surgeon treated stricture

Roman Empire.

of the urethra by internal section. Both Leonides and Antyllus removed glandular swellings of the neck (*strumae*); the latter ligatured vessels before cutting them, and gives directions for avoiding the carotid artery and jugular vein. Flap-amputations were practised by Leonides and Heliodorus. But perhaps the most striking illustration of the advanced surgery of the period is the freedom with which bones were resected, including the long bones, the lower jaw and the upper jaw.

Byzantine. Whatever progress or decadence surgery may have experienced during the next three centuries is summed up in the authoritative treatise of Paulus of Aegina (A.D. 650). Of his seven books the sixth is entirely devoted to operative surgery, and the fourth is largely occupied with surgical diseases. The importance of Paulus for surgical history during several centuries on each side of his own period will appear from the following remarks of Francis Adams (1796–1861) in his translation and commentary (ii. 247):—

"This book (bk. vi.) contains the most complete system of operative surgery which has come down to us from ancient times. . . . Haly Abbas (d. A.D. 994) in the 9th book of his *Practica* copies almost everything from Paulus. Albucasis [Abulcasis] (10th century A.D.) gives more original matter on surgery than any other Arabian author, and yet, as will be seen from our commentary, he is indebted for whole chapters to Paulus. In the *Continens* of Rhases, that precious repository of ancient opinions on medical subjects, if there be any surgical information not to be found in our author it is mostly derived from Antyllus and Archigenes. As to the other authorities, although we will occasionally have to explain their opinions upon particular subjects, no one has treated of surgery in a systematical manner; for even Avicenna, who treats so fully of everything else connected with medicine, is defective in his accounts of surgical operations; and the descriptions which he does give of them are almost all borrowed from our author. The accounts of fractures and dislocations given by Hippocrates and his commentator Galen may be pronounced almost complete; but the information which they supply upon most other surgical subjects is scanty."

Paulus' sixth book, with the valuable commentary of Adams, brings the whole surgery of the ancient world to a focus. Paulus is credited with the principle of local depletion as against general, with the lateral operation for stone instead of the mesial and with understanding the merits of a free external incision and a limited internal, with the diagnosis of aneurism by anastomosis, with an operation for aneurism like that of Antyllus, with amputation of the cancerous breast by crucial incision, and with the treatment of fractured patella.

Arabian. The Arabians have hardly any greater merit in medicine than that of preserving intact the bequest of the ancient world. To surgery in particular their services are small—first, because their religion proscribed the practice of anatomy, and, secondly, because it was a characteristic of their race to accept with equanimity the sufferings that fell to them, and to decline the means of alleviation. The great names of the Arabian school, Avicenna (980–1037) and Averroes (1126–1198), are altogether unimportant for surgery. Their one distinctively surgical writer was Abulcasim (d. 1122), who is chiefly celebrated for his free use of the actual cautery and of caustics. He showed a good deal of character in declining to operate on goitre, in resorting to tracheotomy but sparingly, in refusing to meddle with cancer, and in evacuating large abscesses by degrees.

Medieval. For the five hundred years following the work of Paulus of Aegina there is nothing to record but the names of a few practitioners at the court and of imitators or compilers. Meanwhile in western Europe (apart from the Saracen civilization) a medical school had grown up at Salerno, which in the 10th century had already become famous. From it issued the *Regimen salernitanum*, a work used by the laity for several centuries, and the *Compendium salernitanum*, which circulated among the profession. The decline of the school dates from the founding of a university at Naples in 1224. In its best period princes and nobles resorted to it for treatment from all parts of Europe. The hôtel dieu of Lyons had been founded in 560, and that of Paris a century later. The school of Montpellier was founded in 1025, and became the rallying point of Arabian and Jewish learning. A good deal of the medical and surgical practice was in the hands of the religious orders, particularly of the Benedictines. The practice of surgery by the clergy was at length forbidden by the Council of Tours (1163). The surgical writings of the time were mere reproductions of the classical or Arabian authors. One of the first to go back to independent observation and reflection was William of Saliceto, who belonged to the school of Bologna; his work (1275) advocates the use of the knife in many places where the actual cautery was used by ancient prescription. A greater name in the history of medieval surgery is that of his pupil Lanfranchi of Milan, who migrated (owing to political troubles) first to Lyons and then to Paris. He distinguished between arterial and venous haemorrhage, and is said to have used the ligature for the former. Contemporary with him in France was Henri de Mondeville (Hermondaville) of the school of Montpellier, whose teaching is best known through that of his more famous pupil Guy de Chauliac; the *Chirurgie* of the latter bears the date of 1363, and marks the advance in precision which the revival of anatomy by Mondino had made possible. Eighteen years before Lanfranchi came to Paris a college of surgeons was founded there (1279) by Pitard, who had accompanied St Louis to Palestine as his surgeon. The college was under the protection of St Cosmas and St Damianus, two practitioners of medicine who suffered martyrdom in the reign of Diocletian, and it became known as the Collège de St Côme. From the time that Lanfranchi joined it it attracted many pupils. It maintained its independent existence for several centuries, alongside the medical faculty of the university; the corporations of surgeons in other capitals, such as those of London and Edinburgh, were modelled upon it.

The 14th and 15th centuries are almost entirely without interest for surgical history. The dead level of tradition is broken first by two men of originality and genius—P. Paracelsus (1493–1541) and Paré, and by the revival of anatomy at the hands of Andreas Vesalius (1514–1564) and Gabriel Fallopius (1523–1562), professors at Padua. Apart from the mystical form in which much of his teaching was cast, Paracelsus has great merits as a reformer of surgical practice. *Paracelsus.* "The high value of his surgical writings," says Häser, "has been recognized at all times, even by his opponents." It is not, however, as an innovator in operative surgery, but rather as a direct observer of natural processes, that Paracelsus is distinguished. His description of "hospital gangrene," for example, is perfectly true to nature; his numerous observations on syphilis are also sound and sensible; and he was the first to point out the connexion between cretinism of the offspring and goitre of the parents. He gives most prominence to the healing of wounds. His special surgical treatises are *Die kleine Chirurgie* (1528) and *Die grosse Wund-Arznei* (1536–1537) —the latter being the best known of his works. Somewhat later in date, and of much greater concrete importance for surgery than Paracelsus, is Ambroise Paré (1510–1590). *Paré.* He began life as apprentice to a barber-surgeon in Paris and as a pupil at the hôtel dieu. His earliest opportunities were in military surgery during the campaign of Francis I. in Piedmont. Instead of treating gunshot wounds with hot oil, according to the practice of the day, he had the temerity to trust to a simple bandage; and from that beginning he proceeded to many other developments of rational surgery. In 1545 he published at Paris *La Méthode de traicter les playes faictes par hacquebutes et aultres bastons à feu*. The same year he began to attend the lectures of Sylvius, the Paris teacher of anatomy, to whom he became prosector; and his next book was an *Anatomy* (1550). His most memorable service was to get the use of the ligature for large arteries generally adopted, a method of controlling the haemorrhage which made amputation on a large scale possible for the first time. Like Paracelsus, he writes in the language of the people, while he is free from the encumbrance of mystical theories, which detract from the merits of his fellow reformer in Germany. It is only in his book on monsters, written towards the end of his career, that he shows himself to have been by no means free from superstition. Paré was adored by the army and greatly esteemed by successive

French kings; but his innovations were opposed, as usual, by the faculty, and he had to justify the use of the ligature as well as he could by quotations from Galen and other ancients.

16th Century.

Surgery in the 16th century recovered much of the dexterity and resource that had distinguished it in the best periods of antiquity, while it underwent the developments opened up to it by new forms of wounds inflicted by new weapons of warfare. The use of the staff and other instruments of the "apparatus major" was the chief improvement in lithotomy. A "radical cure" of hernia by sutures superseded the old application of the actual cautery. The earlier modes of treating stricture of the urethra were tried; plastic operations were once more done with something like the skill of Brahmanical and classical times; and ophthalmic surgery was to some extent rescued from the hands of ignorant pretenders. It is noteworthy that even in the legitimate profession dexterous special operations were kept secret; thus the use of the "apparatus major" in lithotomy was handed down as a secret in the family of Laurence Colot, a contemporary of Paré's.

17th Century.

The 17th century was distinguished rather for the rapid progress of anatomy and physiology, for the Baconian and Cartesian philosophies, and the keen interest taken in complete systems of medicine, than for a high standard of surgical practice. The teaching of Paré that gunshot wounds were merely contused and not poisoned, and that simple treatment was the best for them, was enforced anew by Magati (1579–1647), Wiseman and others. Trephining was freely resorted to, even for inveterate migraine; Philip William, prince of Orange, is said to have been trephined seventeen times. Flap-amputations, which had been practised in the best period of Roman surgery by Leonides and Heliodorus, were reintroduced by Lowdham, an Oxford surgeon, in 1679, and probably used by Wiseman, who was the first to practise the primary major amputations. Fabriz von Hilden (1560–1634) introduced a form of tourniquet, made by placing a piece of wood under the bandage encircling the limb; out of that there grew the block-tourniquet of Morel, first used at the siege of Besançon in 1674; and this, again, was superseded by Jean Louis Petit's (1674–1750) screw-tourniquet in 1718. Strangulated hernia, which was for long avoided, became a subject of operation. Lithotomy by the lateral method came to great perfection in the hands of Jacques Beaulieu. To this century also belong the first indications (not to mention the Alexandrian practice of Ammonius) of crushing the stone in the bladder. The theory and practice of transfusion of blood occupied much attention, especially among the busy spirits of the Royal Society, such as Boyle, Lower and others. The seat of cataract in the substance of the lens was first made out by two French surgeons, Quarré and Lasnier. Perhaps the most important figure in the surgical history of the century is Richard Wiseman (1622?–1676) the father of English surgery.

Wiseman.

Wiseman took the Royalist side in the wars of the Commonwealth, and was surgeon to James I. and Charles I., and accompanied Charles II. in his exile in France and the Low Countries. After serving for a time in the Spanish fleet, he joined the Royalist cause in England and was taken prisoner at the battle of Worcester. At the Restoration he became serjeant-surgeon to Charles II., and held the same office under James II. His *Seven Chirurgical Treatises* were first published in 1676, and went through several editions; they relate to tumours, ulcers, diseases of the anus, king's evil (scrofula), wounds, fractures, luxations and lues venerea. Wiseman was the first to advocate primary amputation (or operation before the onset of fever) in cases of gunshot wounds and other injuries of the limbs. He introduced also the practice of treating aneurisms by compression, gave an accurate account of fungus articulorum, and improved the operative procedure for hernia.

The 18th century marks the establishment of surgery on a broader basis than the skill of individual surgeons of the court and army, and on a more scientific basis than the rule of thumb of the multitude of barber-surgeons and other inferior orders of practitioners. In Paris the Collège de St Côme gave way to the Academy of Surgery in 1731, with Petit as director, to which was added at a later date the École Pratique de Chirurgie, with François Chopart (1743–1795) and Pierre Desault (1744–1795) among its first professors.

18th Century.

The Academy of Surgery set up a very high standard from the first, and exercised great exclusiveness in its publications and its honorary membership. In London and Edinburgh the development of surgery proceeded on less academical lines, and with greater scope for individual effort. Private dissecting rooms and anatomical theatres were started, of which perhaps the most notable was Dr William Hunter's (1718–1783) school in Great Windmill Street, London, inasmuch as it was the first perch of his more famous brother John Hunter (1728–1793). In Edinburgh, Alexander Monro (1697–1767), first of the name, became professor of anatomy to the company of surgeons in 1719, transferring his title and services to the university the year after; as he was the first systematic teacher of medicine or surgery in Edinburgh, he is regarded as the founder of the famous medical school of that city. In both London and Edinburgh a company of barbers and surgeons had been in existence for many years before; but it was not until the association of these companies with the study of anatomy, comparative anatomy, physiology and pathology that the surgical profession began to take rank with the older order of physicians. Hence the significance of the eulogy of a living surgeon on John Hunter: "More than any other man he helped to make us gentlemen" (*Hunterian Oration*, 1877). The state of surgery in Germany may be inferred from the fact that the teaching of it at the new university of Göttingen was for long in the hands of Albrecht von Haller (1708–1777), whose office was "professor of theoretical medicine." In the Prussian army it fell to the regimental surgeon to shave the officers. At Berlin a medico-chirurgical college was founded by Surgeon-General Ernst von Holtzendorff (1688–1751) in 1714, to which was joined in 1726 a school of clinical surgery at the Charité. Military surgery was the original purpose of the school, which still exists, side by side with the surgical cliniques of the faculty, as the Friedrich Wilhelm's Institut. In Vienna, in like manner, a school for the training of army surgeons was founded in 1785—Joseph's Academy or the Josephinum. The first systematic teaching of surgery in the United States was by Dr Shippen at Philadelphia, where the medical college towards the end of the century was largely officered by pupils of the Edinburgh school. A great part of the advance during the 18th century was in surgical pathology, including Petit's observations on the formation of thrombi in severed vessels, Hunter's account of the reparative process, Benjamin Bell's classification of ulcers, the observations of Duhamel and others on the formation of callus and on bone-repair in general, Pott's distinction between spinal curvature from caries or abscess of the vertebrae and kyphosis from other causes, observations by various surgeons on chronic disease of the hip, knee, and other joints, and Cheselden's description of neuroma. Among the great improvements in surgical procedure we have Cheselden's operation of lithotomy (six deaths in eighty cases), Sir Caesar Hawkins's (1711–1786) cutting gorget for the same (1753), Hunter's operation (1785) for popliteal aneurism by tying the femoral artery in the canal of the triceps where its walls were sound ("excited the greatest wonder," Assalini), Petit's, Desault's and Percival Pott's (1714–1788) treatment of fractures, Gimbernat's (Barcelona) operation for strangulated femoral hernia, Pott's bistoury for fistula, Charles White's (1728–1813, Manchester) and Henry Park's (1745–1831, Liverpool) excision of joints, Petit's invention of the screw-tourniquet, the same surgeon's operation for lacrymal fistula, Chopart's partial amputation of the foot, Desault's bandage for fractured clavicle, William Bromfield's (1712–1792) artery hook, and William Cheselden's (1688–1752) operation of iridectomy. Other surgeons of great versatility and general merit were Sharp of London, Benjamin Gooch (*fl.* 1775) of Norwich, William Hey (1736–1819) of Leeds, David and Claude Nicolas Le Cat (1705–1768) of Rouen, Raphaël Sabatier (1732–1811), Georges de La

Faye (1701–1781), Ledran, Antoine Louis (1723–1792), Sauveur Morand (1697–1773) and Pierre Percy (1754–1825) of Paris, Bertrandi of Turin, Troja of Naples, Palleta of Milan, Schmucker of the Prussian army, August Richter of Göttingen, Siebold of Würzburg, Olaf Acrel of Stockholm and Callisen of Copenhagen.

19th Century.

Two things gave surgical knowledge and skill in the 19th century a character of scientific or positive cumulativeness and a wide diffusion through all ranks of the profession.[1] The one was the founding of museums of anatomy and surgical pathology by the Hunters, Guillaume Dupuytren (1777–1835), Jules Cloquet (1790–1843), J. F. Blumenbach (1752–1840), John Barclay (1758–1826), and a great number of more modern anatomists and surgeons; the other was the method of clinical teaching, exemplified in its highest form of constant reference to principles by Thomas Lawrence (1711–1783) and James Syme (1799–1870). In surgical procedure the discovery of the anaesthetic properties of ether, chloroform, methylene, &c., was of incalculable service; while the conservative principle in operations upon diseased or injured parts, and especially what may be called the hygienic idea (or, more narrowly, the antiseptic and aseptic principles) in the conditions governing surgery, were strikingly beneficial.

The following were among the more important additions to the resources of the surgical art: the thin thread ligature for arteries, introduced by Jones of Jersey (1805); the revival of torsion of arteries by Jean Amussat (1796–1856). [1829]; the practice of drainage by Pierre Marie Chassaignac (1805–1879) [1859]; aspiration by Philippe Pelletan (1747–1829) and recent improvers; the plaster-of-Paris bandage or other immovable application for simple fractures, club-foot, &c. (an old Eastern practice recommended in Europe about 1814 by the English consul at Basra); the re-breaking of badly set fractures; galvano-caustics and écraseurs; the general introduction of resection of joints (Sir William Fergusson (1808–1877), Syme and others); tenotomy by Jacques Delpech (1777–1832) and Louis Stromeyer (1804–1876) [1831]; operation for squint by Johann Dieffenbach (1795–1847) [1842]; successful ligature of the external iliac for aneurism of the femoral by John Abernethy (1764–1831) [1806]; ligature of the subclavian in the third portion by Astley Cooper (1768–1841) [1806], and in its first portion by Colles; crushing of stone in the bladder by Gruithuisen of Munich (1819) and Jean Civiale (1792–1867) of Paris [1826]; cure of ovarian dropsy by removing the cyst (since greatly perfected); discovery of the ophthalmoscope, and many improvements in ophthalmic surgery by Alfred von Gräfe (1830–1899) and others; application of the laryngoscope in operations on the larynx by Jean Czermak (1828–1873) [1860] and others; together with additions to the resources of aural surgery and dentistry. The great names in the surgery of the first half of the century besides those mentioned are: Antonio Scarpa of Italy (1747–1832); Alexis Boyer (1757–1833), Félix Larrey (1766–1842)—to whom Napoleon left a legacy of a hundred thousand francs, with the eulogy: "C'est l'homme le plus vertueux que j'aie connu," Philibert Roux (1780–1854), Jacques Lisfranc (1790–1847), Alfred Louis Velpeau (1795–1868), Joseph Malgaigne (1806–1865), Auguste Nélaton (1807–1873)—all of the French school; of the British school, John Bell (1763–1820), Charles Bell (1774–1842), Allan Burns (1781–1813), Robert Liston (1794–1847), James Wardrop (1782–1869), Astley Cooper, Henry Cline (1750–1827), Benjamin Travers (1783–1858), Benjamin Brodie (1783–1862), Edward Stanley (1793–1862) and George Guthrie (1785–1856); in the United States, V. Mott, S. D. Gross and others; in Germany, Kern and Schuh of Vienna, Von Walther and Textor of Würzburg, Chelius, Hesselbach and the two Langenbecks—Konrad (1776–1851) and Bernhard (1810–1887).

Medicin* (3rd ed., 1875–1881), vols. i. and ii. (C. C.)

Modern Practice of Surgery.[2]—A great change has taken place in the practice of surgery since the middle of the 19th century, in consequence of the new science of bacteriology, and the introduction of aseptic methods, due to the teaching of Lord Lister.

It had long been known that subcutaneous injuries followed a far more satisfactory course than those with wounds, and the history of surgery gives evidence that surgeons endeavoured, by the use of various dressings, empirically to prevent the evils which were matters of common observation during the healing of open wounds. Various means were also adopted to prevent the entrance of air, as, for instance, in the opening of abscesses by the "valvular method" of Abernethy, and by the subcutaneous division of tendons in "club-foot." Balsams and turpentine and various forms of spirit were the basis of many varieties of dressing. These different dressings were frequently cumbersome and difficult of application, and they did not attain the object aimed at, while, at the same time, they shut in the discharges and gave rise to other evils which prevented rapid and painless healing. In the beginning of the 19th century these complicated dressings began to lose favour, and operating surgeons went to the opposite extreme and applied a simple dressing, the main object of which was to allow a free escape of discharge. Others applied no dressing at all, laying the stump of a limb after amputation on a piece of dry lint, avoiding thereby any unnecessary movement of the parts. Others, again, left the wound open for some hours after an operation, preventing in this way any accumulation, and brought its edges and surfaces together after all oozing of blood had ceased, and after the effusion, the result of injury to the tissues in the operation had to a great extent subsided. As a result of these measures many wounds healed kindly. But in other cases inflammation occurred, accompanied by pain and swelling, and the formation of pus. High fever also, due to the unhealthy state of the wound, was observed. These conditions often proved fatal, and surgeons attributed them to the constitution of the patient, or else thought that some poison had entered the wound, and, passing from it into the veins, had contaminated the blood and poisoned the patient. The close association between the formation of pus in wounds and the fatal "intoxication" of many of those cases encouraged the belief that the pus cells from the wound entered the circulation. Hence came the word "pyaemia." It was also observed that a septic condition of the wound was usually associated with constitutional fever, and it was supposed that the septic matter passed into the blood—whence the term "septicaemia." It was further observed that the crowding together of patients with open wounds increased the liability to these constitutional disasters, so every endeavour was made to separate the patients and to improve ventilation. In building hospitals the pavilion and other systems, with windows on both sides, with cross-ventilation in the wards, were adopted in order to give the utmost amount of fresh air. Hospital buildings were spread over as large an area as possible, and were restricted in height, if practicable, to two storeys. The term "hospitalism" was coined by Sir J. Y. Simpson, who collected statistics comparing hospital and private practice, by which he endeavoured to show that private patients were far less liable to such catastrophes than were those who were treated in hospitals.

Antiseptic Surgery.

This was the condition of affairs when Lister in 1860, from a study of the experimental researches of Pasteur into the causes of putrefaction, stated that the evils observed in open wounds were due to the admission into them of organisms which exist in the air, in water, on instruments, on sponges, and on the hands of the surgeon or the skin of the patient. Having accepted the germ theory of putrefaction, Lister applied himself to discover the best way of preventing all harmful organisms from reaching the wound from the moment that it was made until it was healed. In the germ he had to deal with a microscopic plant, and he desired to render its growth impossible. This, he thought, could be done either by destroying the plant itself before it had the chance of entering the wound or after it had entered, or by facilitating the removal of the discharges and preventing their accumulation in the wound, and by doing everything to prevent the lowering of the vitality of the wounded tissues, because unhealthy tissues are the most liable to attack. Several substances were then known as possessing properties antagonistic to sepsis or putrefaction, and hence called "antiseptic." Acting on a suggestion of Lemaire, Lister chose for his experiments carbolic acid, which he used at first in a crude form. He had many difficulties to contend with—the impurity of the substance.

[1] The Royal College of Surgeons in London was established in 1800, the title being changed in 1843 to Royal College of Surgeons of England.

[2] For the surgery of any particular region or organ, reference should be made to the article on that region or organ.

its irritating properties and the difficulty of finding the exact strength in which to use it: he feared to use it too strong, lest it should impair the vitality of the tissues and thus prevent healing; and he feared to use it too weak, lest its antiseptic qualities should be insufficient for the object in view. As dressings for wounds he used various chemical substances, which, being mixed with carbolic acid, were intended to give off a certain quantity of carbolic acid in the form of vapour, so that the wound might be constantly surrounded by an antiseptic which would destroy any organisms approaching it, and, at the same time, not interfere with its healing. At first, although he prevented pyaemia in a marked degree, he, to a certain extent, irritated the wounds and prevented rapid healing. He began his historic experiments in Glasgow and continued them on his removal to the chair of clinical surgery in Edinburgh. After many disappointments, he gradually perfected his method of performing operations and dressing wounds, which was somewhat as follows.

A patient was suffering, for instance, from disease of the foot necessitating amputation at the ankle joint. The part to be operated on was enveloped in a towel soaked with a 5% solution of carbolic acid. The towel was applied two hours before the operation, with the object of destroying the putrefactive organisms present in the skin. The patient was placed on the operating table, and brought under the influence of chloroform; the limb was then elevated to empty it of blood, and a tourniquet was applied round the limb below the knee. The instruments to be used during the operation had been previously purified by lying for half an hour in a flat porcelain dish containing carbolic acid (1 in 20). The sponges lay in a similar carbolic lotion. Towels soaked in the same solution were laid over the table and blankets near the part to be operated upon. The hands of the operator, as well as those of his assistants, were thoroughly cleansed by washing them in carbolic lotion, free use being made of a nail brush for this purpose. The operation was performed under a cloud of carbolized watery vapour (1 in 30) from a steam spray-producer. The visible bleeding points were first ligated; the tourniquet was removed; and any vessels that had escaped notice were secured. The wound was stitched, a drainage-tube made of red rubber being introduced at one corner to prevent accumulation of discharge; a strip of "protective"—oiled silk coated with carbolized dextrin—was washed in carbolic lotion and applied over the wound. A double ply of carbolic gauze was soaked in the lotion laid over the protective, overlapping it freely. A dressing consisting of eight layers of dry gauze was placed over all, covering the stump and passing up the leg for about six inches. Over that a piece of thin mackintosh cloth was placed, and the whole arrangement was fixed with a gauze bandage. The mackintosh cloth prevented the carbolic acid from escaping and at the same time caused the discharge from the wound to spread through the gauze. The wound itself was shielded by the protective from the vapour given off by the carbolic gauze, whilst the surrounding parts, being constantly exposed to its activity, were protected from the intrusion of septic contamination. And these conditions were maintained until sound healing took place. Whenever the discharge reached the edge of the mackintosh the case required to be dressed, and a new supply of gauze was applied round the stump. Whenever the wound was exposed for dressing the stump was enveloped in the vapour of carbolic acid by means of the steam spray-producer. At first a syringe was used to keep the surface constantly wet with lotion and then a hand-spray. These dressings were repeated at intervals until the wound was healed. The drainage-tube was gradually shortened, and was ultimately removed altogether.

The object Lister had in view from the beginning of his experiments was to place the open wound in a condition as regards the entrance of organisms as nearly as possible like a truly subcutaneous wound, such as a contusion or a simple fracture, in which the unbroken skin acted as a protection to the wounded tissues beneath. The introduction of this practice by Lister effected a complete change in operative surgery. The dark times of suppurating wounds, of foul discharges, of secondary haemorrhage, of pyaemic abscesses and hospital gangrene constitute what is now spoken of in surgery as the pre-Listerian era.

As years went on, surgeons tried to simplify and improve the somewhat complicated and expensive measures and dressings and chemists were at pains to supply carbolic acid in a pure form and to discover new antiseptics, the great object being to get a non-irritating antiseptic which should at the same time be a powerful germicide. Iodoform, oil of eucalyptus, salicylic acid, boracic acid, mercuric iodide, and corrosive sublimate were used.

For some years Lister irrigated a wound with carbolic lotion during the operation and at the dressings when it was exposed, but the introduction of the spray displaced the irrigation method. All these different procedures, however, as regards both the antiseptic used and the best method of its application in oily and watery solutions and in dressings, were subsidiary to the great principle involved—namely, that putrefaction in a wound is an evil which can be prevented, and that, if it is prevented, local irritation, in so far as it is due to putrefaction, is obviated and septicaemia and pyaemia cannot occur. Alongside of this great improvement the immense advantage of free drainage was universally acknowledged. Moreover, surgeons at once began to take greater care in securing the cleanliness of wounds, and some of them, Lawson Tait and Bantock, for example, produced such excellent results by the adoption merely of methods of strict cleanliness, and became so aggressive in their championship of them, that many of the older practitioners were bewildered and unable to decide as to where truth began and where it ended in the new doctrine. But though the actual methods, as taught and practised by Lister, have, with the spray-producers, passed away and given place to new, still the great light which he shed in the surgical world burns as brightly as ever it did; and all the methods which are practised to-day are the direct results of his teaching.

By 1885 the carbolic acid spray, which to some practitioners had apparently been the embodiment of the Listerian theory and practice, was beginning to pass into desuetude, though for a good many years after that time certain surgeons continued to employ it during operation, and during the subsequent dressings of the wound. Surgeons who, having had practical experience of the unhappy course which their operation-cases had been apt to run in the pre-Listerian days, and of the vast improvements which ensued on their adoption of the spray-and-gauze method in its entirety, were, not unnaturally, reluctant to operate except in a cloud of carbolic vapour. So, even after Lister himself had given up the spray, its use was continued by many of his disciples. It was in the course of 1888 that operating surgeons began to neglect the letter of the antiseptic treatment and to bring themselves more under the broadening influence of its spirit. Certain adventurous and partially unconvinced surgeons began to give up the carbolic spray gradually, by imparting a smaller percentage of carbolic acid to the vapour, until at last the antiseptic disappeared altogether, apparently without detriment to the excellence of the results obtained. But while some surgeons were thus ceasing to apply the antiseptic spray to the wound during operation, others were pouring mild carbolic lotion, or a very weak solution of corrosive sublimate (an extremely potent germicide) over the freshly-cut surfaces. These measures were in turn given up, to the advantage of the patient; for it was hardly to be expected that a chemical agent which was strong enough to destroy or render inert septic micro-organisms in and about a wound would fail to injure exposed and living tissues. Eventually it became generally admitted that if a surgeon was going to operate upon the depths of an open abdomen for an hour or more, the chilling and the chemical influences of the spray must certainly lower the vitality of the parts exposed, as well as interfere with the prompt healing of the wounded surfaces. With the spray went also the "protective," the paraffin gauze, and the mackintosh sheeting which enveloped the bulky dressing.

Years before this happened, in the address on surgery given at the Cork meeting of the British Medical Association, Sir William (then Mr) Savory had somewhat severely criticized the rigid exclusiveness of the members of the spray-and-gauze school: the sum and substance of the address was that every careful surgeon was an antiseptic surgeon, and that the success of the Listerian surgeon did not depend upon the spray or the gauze, or the two together, but upon *cleanliness*—that the surgeon's fingers and instruments and the area operated on must be *surgically clean*. Though precise experiments show that it is impossible for the surgeon to remove every trace of septicity from his own hands and from the skin of his patient, still with nail-brush, soap and water, and alcohol or turpentine, with possibly the help of some mercuric germicide, he can, for all practical purposes, render his hands safe. Recognizing this difficulty many surgeons prefer to operate in thin rubber gloves which can, for certain, by boiling, be rendered free of all germs; others, in addition, put on a mask, sterile overalls, and india-rubber shoes. But these excessive refinements do not seem to be generally acceptable, whilst the results of practice show that they are by no means necessary. The careful, the antiseptic surgeon of 1885 is to-day represented by the careful, the *aseptic* surgeon. The *antiseptic* surgeon was waging a constant warfare against germs which his creed told him were on his hands, in the wound, in the air, everywhere—and these he attacked with potent chemicals which beyond question often did real damage to the healthy tissues laid bare during the operation. If, as was frequently the case, his own hands became sore and rough from contact with the antiseptics he employed, it was not to be wondered at if a peritoneal surface or an incised tissue became more seriously affected. The surgeon of to-day has much less commerce with antiseptics: he operates with hands which, for all practical purposes, may be considered as germless; he uses instruments which are certainly germless, for they have just been boiled for twenty minutes in water (to which a little common soda has been added to prevent tarnishing of the steel), and he operates on tissues which have been duly made clean in a surgical sense. If he were asked what he considers the chief essentials for securing success in his operative practice, he would probably reply, "Soap and water and a nail-brush." He uses no antiseptics during the operations, he keeps the wound dry by gently swabbing it with aseptic, absorbent cotton-wool, and he dresses it with a pad of aseptic gauze. This is the simple aseptic method which has been gradually evolved from the Listerian antiseptic system. But though the pendulum has swung so far in the direction of *aseptic* surgery, a very large proportion of operators still adhere to the *antiseptic* measures which had proved so highly beneficial. The judicious employment of weak solutions of carbolic acid, or of mercuric salts, and the application of unirritating dressings of an antiseptic nature cannot do any harm, and, on the other hand, they may be of great service in the case of there having been some flaw in the carrying out of what should have been an absolutely aseptic operation.

Aseptic Surgery.

A great change has taken place in connexion with the use of soft india-rubber drainage-tubes. In former years most surgeons placed one or more of these in the dependent parts of the area of operation, so that the blood or serum oozing from the injured tissues might find a ready escape. But to-day, except in dealing with a large abscess or other septic cavity, many surgeons make no provision for drainage, but, bandaging the part beneath a pad of aseptic wool, put on so much pressure that any little leakage into the tissues is quickly absorbed. If a drainage-tube can be dispensed with, so much the better, for if it is not actually needed its presence keeps up irritation and delays prompt healing. But inasmuch as a tube if rightly placed in a deep wound is an insurance against the occurrence of "tension," and as it can easily be withdrawn at the end of twenty-four hours (even if it has served no useful purpose), it is improbable that the practice of drainage of freshly made cavities will ever be entirely given up. If the tube is removed after twenty-four hours its presence can have done no harm and sometimes the large amount of fluid which it has drained from the wound affords clear evidence that its use has saved the patient discomfort and has probably expedited his recovery. For septic cavities drainage-tubes are still used, but it must be remembered that the tube cannot remain long in position without causing and keeping up irritation; hence, even in septic cases, the modern surgeon discards the tube at the earliest possible moment. If after he has taken it out septic fluids collect, and the patient's temperature rises, it can easily be reinserted. But it is better to take out the tube too soon than to leave it in too long; this remark applies with special force to the treatment of abscess of the pleural cavity (empyema), in the treatment of which a drainage-tube has almost certainly to be employed.

Drainage-tubes.

Poultices are now never used: they were apt to be foul and offensive, and were certainly septic and dangerous. If moisture and warmth are needed for a wound they can be obtained by the use of a fold of clean lint, or by some aseptic wool which has been wrung out in a hot solution of boracic or carbolic acid, and applied under some waterproof material, which effectually prevents evaporation and chilling. There was no special virtue in poultices made of linseed meal or even of scraped carrot: they simply stored up the moisture and heat. They possessed no possible advantage over the modern fomentation under oil-silk.

Much less is heard now of so-called "bloodless" operations. The bloodlessness was secured by the part to be operated on—an arm, for instance—being raised and compressed from the fingers to the shoulder by successive turns of an india-rubber roller-bandage (Esmarch's), the main artery of the limb being then compressed by the application of an elastic cord above the highest turn of the bandage. The bandage being removed, the operation was performed through bloodless tissues. But when it was completed and the elastic cord removed from around the upper part of the limb, a reactionary flow of blood took place into every small vessel which had been previously squeezed empty, so that though the operation itself had actually been bloodless, the wound could not be closed because of the occurrence of unusually free haemorrhage or troublesome oozing. A further objection to the application of such an elastic roller-bandage was that septic or tuberculous material might by chance be squeezed from the tissues in which it was perhaps harmlessly lying, forced into the blood vessels, and so widely disseminated through the body. Esmarch's bandage is therefore but little used now in operative surgery. Instead, each bleeding point at an operation is promptly secured by a small pair of nickel-plated clip-forceps, which generally have the effect, after being left on for a few minutes, of completely and permanently arresting the bleeding. These clips were specially introduced into practice by Sir Spencer Wells, and it is no unusual thing for a surgeon to have twenty or thirty pairs of them at hand during an extensive operation. Seeing how convenient, not to say indispensable, they are in such circumstances, the surgeon of to-day wonders how he formerly managed to get on at all without them.

Bloodless Operations.

Biers's treatment by passive congestion is carried out by gently assisting the return of venous blood from a part of the body without in any way checking the arterial flow. In the case of tuberculous disease of the knee-joint, for instance, an elastic band is gently placed round the thigh for several hours a day, and in disease of the wrist or elbow the girth is applied round the arm. The skin below becomes flushed, and the arterial blood which, as shown by the pulse, is still flowing into the affected part, is compelled to linger in the affected tissues, giving the serum and the white corpuscles time to exert their beneficial influence upon the disease.

In the case of tuberculous, or septic, affections of the lymphatic glands of the neck, or of other parts where the constriction cannot be conveniently obtained, effective congestion can be secured by the use of cupping glasses. And if so be that suppuration is taking place in the interior of an inflamed gland, the cupping-glasses can be applied after a small puncture has been made into the softened part of the gland. In this way the whole of the broken-down material can be got away without the necessity of making an actual *incision* or of resorting to scraping. The method of inducing hyperaemia should be so conducted as to give the patient no pain whatever: it must not be carried out with excessive energy.

Röntgen Rays.

By means of the Röntgen or X-rays (see X-Ray Treatment) the surgeon is able to procure a distinct shadow-portrait of deeply-placed bones, so that he can be assured as to the presence or absence of fracture or dislocation, or of outgrowth of bone, or of bone-containing tumours. By this means also he is able to locate with absolute precision the situation of a foreign body in the tissues—of a coin in the windpipe or gullet, of a broken piece of a needle in the hand, of a splinter of glass in the foot, or of a bullet deeply embedded in soft tissues or bone. This effect may be obtained upon a fluorescent screen or printed in a permanent form upon glass or paper. The shadow is cast by a 10- or 12-in. spark from a Crookes vacuum tube. The rays of Röntgen find their way through dead and living tissues which are far beyond the reach of the rays of ordinary light, and they are thus able even to reveal changes in the deeply placed hip-joint which have been produced by tuberculous disease. In examining an injured limb it is not necessary to take off wooden splints or bandages except in cases where the latter have been treated with plaster of paris, lime-salts obstructing the rays and throwing a shadow. Thus the rays may pass through an ordinary uric acid calculus in the kidney or bladder; but if it contains salts of lime, as does the mulberry calculus (oxalate of lime), a definite shadow is cast upon the screen. The value of the X-rays is not limited to the elucidation of obscure problems such as those just indicated: they are also of therapeutic value; for example, in the treatment of certain forms of skin disease, as well as of cancer.

Too much, however, must not be expected from them. For the treatment of a patch of tuberculous ulceration (lupus), or for a superficial cancerous sore (epithelioma), they may be of service, but in the treatment of a deeply-seated malignant growth—as a cancer of the breast—they have not proved of value. Moreover, the X-rays sometimes cause serious burns of the skin; and although this happens less often now than was previously the case, still the frequent application of the rays is apt to be followed by cutaneous warty growths which are apt in turn to develop into cancer. In many cases in which the X-rays are used a more prompt and efficient means of treatment would probably be by excision. One great advantage which operative treatment by the knife must always have over the treatment by X-rays is that the secondary implication of the lymphatic glands can be dealt with at the same time. And this, in many cases, is a matter of almost equal importance to that of removal of the cancer itself.

Radium.

The employment of radium in surgery is still in its infancy. Doubtless radium is a very powerful agent, but even if it were found of peculiar value in treatment its cost would, for the present, put it out of the reach of most practitioners. Probably it will be found useful in the treatment of naevus, rodent ulcers and superficial malignant growths. As to what influence radium may have in the treatment of deeply-seated cancers it is as yet impossible even to guess. For those sad cases, however, which the practical surgeon is reluctantly compelled to admit as being beyond the reach of his operative skill, the influence of radium should be tried with determination and thoroughness. The therapeutic influence of radium may eventually be found to be great, or it may be disappointing. The fact that under direct royal patronage an institution has been established in London for the investigation of the physical and therapeutic value of this newly discovered agent should satisfy every one that its properties will be duly inquired into and made known without mystery or charlatanism and absolutely in the interest of the people. But in the meanwhile too much must not be expected from it as a surgical agent. (E. O.*)

SURGICAL INSTRUMENTS AND APPLIANCES. The purpose of this article is to give an account of the more important surgical instruments that are now in general use, and to show by what modifications, and from what discoveries in science, the present methods of an operation have come to be what they are. The good surgeon is careful to use the right sort and pattern of instrument, and the chief fact about the surgery of the present day, that it is aseptic or antiseptic, is recorded in the make of surgical instruments and in all the installation of an operating-theatre. Take, for instance, a scalpel and a saw that are figured in Ambroise Paré's (1510–1590) surgical writings. The scalpel folds into a handle like an ordinary pocket-knife, which alone was enough in those days to keep it from being aseptic. The handle is most elegantly adorned with a little winged female figure, but it does not commend itself as likely to be surgically

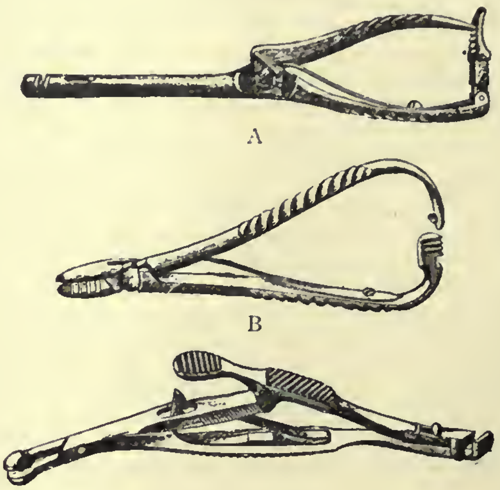

Fig. 1.—Needle-holders.
A, Hagedorn's; B, Macphail's; C, Allen and Hanbury's, for Hagedorn or ordinary needles.

clean. The saw, after the same fashion, has a richly chased metal frame, and, at the end of the handle, a lion's head in bold relief, with a ring through its mouth to hang it up by. It may be admirable art, but it would harbour all sorts of germs. If one contrasts with these artistic weapons the

Fig. 2.—Tenotomy Knives forged in one piece.

instruments of 1850, one finds no such adornment, and for general finish Savigny's instruments would be hard to beat; but the wooden or ivory handles, cut with finely scored lines like the cross-hatching of an engraving, are not more likely to be aseptic than the handles of Paré's instruments. At the present time, instead of such handles as these, with blades riveted into them, scalpels are forged out of one piece of steel, their handles are nickel-plated and perfectly smooth, that they may afford no crevices, and may be boiled and immersed in carbolic lotion without tarnishing or rusting; the scalpel has become just a single, smooth, plain piece of metal, having this one purpose that it shall make an aseptic wound. In the same way the saw is made in one piece, if this be possible; anyhow, it must be, so far as possible, a simple, smooth, unrusting metal instrument, that can be boiled and laid in lotion; it is a foreign body that must be introduced into tissues susceptible of infection, and it must not carry infection with it.

Or we may take, at different periods of surgery, the various kinds of ligature for the arrest of bleeding from a divided blood-vessel. In Paré's time (he was the first to use the ligature in amputation, but the existence of some sort of ligature is as old as Galen) the ligature was a double thread, *bon fil qui soit en double*; and he employed a forceps to draw forward the cut end of the vessel to be ligatured. From the time of Ambroise Paré to the time of Lord Lister no great improvement was made. In the middle of last century it was no uncommon thing for the house-surgeon at an operation to hang a leash of waxed threads, silk or flax, through his button-hole, that they might

FIG. 3.—Amputating Saws.

be handy during the operation. Then came Lord Lister's work on the absorbable ligature; and out of this and much other experimental work has come the present use of the ligature in its utmost perfection—a thread that can be tied, cut short, and left in the depth of the wound, with absolute certainty that the wound may at once be closed from end to end and nothing more will ever be heard of the ligatures left buried in the tissues. The choice of materials for the ligature is wide. Some surgeons prefer catgut, variously prepared; others prefer silk; for certain purposes, as for the obliteration of a vessel not divided but tied in its course for the cure of aneurism, use is made of kangaroo-tendon, or some other animal substance. But whatever is chosen is made aseptic by boiling, and is guarded vigilantly from contamination on its way from the sterilizer into the body of the patient. The old ligatures were a common cause of suppuration. Therefore the wound was not closed along its whole length, but the ligatures were left long, hanging out of one end of the wound, and from day to day were gently pulled until they came away. Certainly they served thus to drain the wound, but they were themselves a chief cause of the suppuration that required drainage.

Sutures, like ligatures, were a common cause of suppuration in or around the edges of the wound. Therefore, in the hope of avoiding this trouble, they were made of silver wire, which was inconvenient to handle, and gave pain at the time of removal of the sutures. At the present time they are of silkworm-gut, catgut, silk or horsehair; they are made aseptic by boiling, and can be left any number of days without causing suppuration and can then be removed without pain.

Next may come the consideration of surgical dressings. In the days when inflammation and suppuration were almost inevitable, the dressings were usually something very simple, that could be easily and frequently changed—ointment, or wet compresses, to begin with, and poultices when suppuration was established. It is reported of the great Sir William Fergusson that he once told his students, "You may say what you like, gentlemen, but after all, there's no better dressing than cold water." This is not the place to try to tell the long history of the quest after a perfect surgical dressing, and the advance that was begun when Lord Lister invented his carbolic paste. The work was done slowly in the international unity of science during many years. The perfect antiseptic dressing must fulfil many requirements: it must be absorbent, yet not let its medicament be too quickly soaked out of it; and it must be antiseptic, yet not virulent or poisonous. Of the many gauzes now available, that which is chiefly used is one impregnated with a double cyanide of zinc and mercury. Its pleasant amethystine tint has no healing virtue, but is used to distinguish it from other gauzes—carbolized gauze, tinted straw-colour; iodoform gauze, tinted yellow; sublimate, blue; chinosol, green. The chinosol gauze is especially used in ophthalmic surgery; for general surgery the cyanide gauze is chiefly employed. The various preparations of absorbent wool (*i.e.* wool that has been freed of its grease, so that it readily takes up moisture) are used not only for outside dressings, but also as sponges at the time of operation, and have to a great extent done away with the use of real sponges. The gauzes in most cases are used not dry, but just wrung out of carbolic lotion, that their antiseptic influence may act at once.

The whole subject of surgical instruments may be considered in more ways than one. It may be well, for the sake of clearing the ground, to take first some of the more common instruments of general

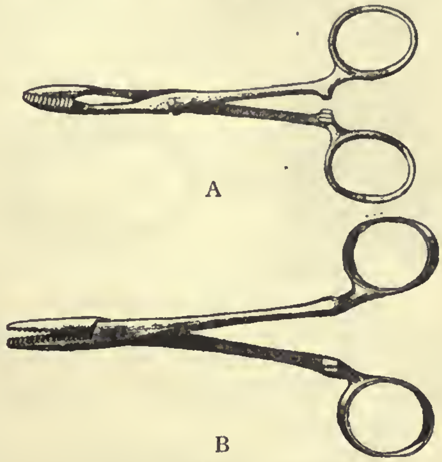

FIG. 4.—Artery Forceps.
A, Péan's; B, Spencer Wells's.

surgery, and then to note the working out, in the operations of surgery, of the three great principles—the use of anaesthetics, the use of antiseptic or aseptic methods, and the surgical uses of electricity.

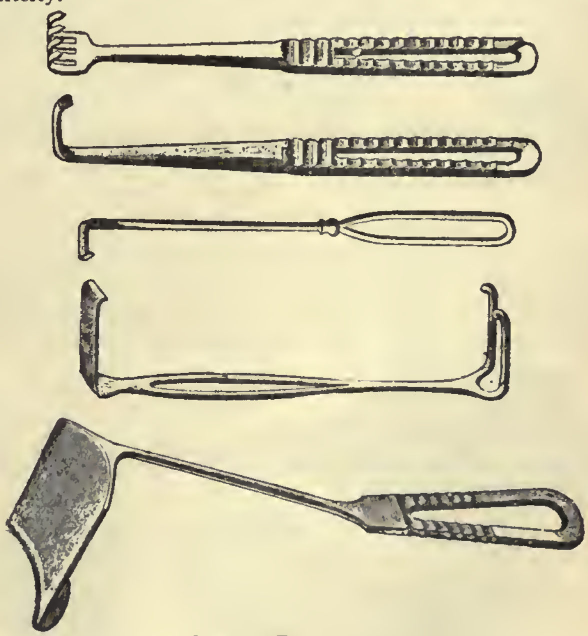

FIG. 5.—Retractors.

Of the essential instruments that are common to all operations, we may well believe that they have now become, by gradual development, perfect. Take, for instance, the ordinary surgical needle. In the older forms the eye was slit-shaped, not easily threaded, and the needle was often made of a triangular outline, like a miniature bayonet. At the present time the needles used in general surgery are mostly Hagedorn's, which have a full-sized round eye, easy for threading, are flat for their whole length and have a fine cutting edge on one side, near the point. Thus they enter the skin very easily, like a miniature knife, and the minute wound they make is not a hole, but a tiny slit that is at once drawn together and, as it were, obliterated by the tying of the suture. Or, for another simple instrument in universal use, take the catch-forceps that is used for taking hold of a bleeding point till it is ligatured. This forceps is as old as the time of Paré, but he made use of a very heavy and clumsy pattern. Up to the last few years the artery-forceps was made with broad, curved, fenestrated blades, with the catch set close to the blades. At the present time the forceps in general use, named after Dr Péan in France and after Sir Spencer Wells in England, is made with very narrow grooved blades, and the catch is placed not near the blades, but near the handles: thus it takes a surer hold, and can be set free when the ligature is tied by a moment's extra pressure on the handles.

Among other instruments in universal use are divers forms of retractors, for holding gently the edges of a wound: the larger patterns are made with broad, slightly-concave, highly-polished surfaces, that they may, so far as possible, reflect light into the wound. Among tourniquets, the old and elaborate Petit's tourniquet, which was a band carrying a pad screwed down over the main artery of the limb, has given place to the elastic tourniquet with Esmarch's bandage. For example, in an amputation, or in an operation on a joint or on a vessel or a nerve in a limb, the limb is

Fig. 6.—Tourniquet (Esmarch's).

raised, and the Esmarch's elastic bandage is applied from below upward till it has reached a point well above the site of the operation; then an elastic tourniquet is wound round the limb at this point, the bandage is removed, and the limb is thus kept almost bloodless during the operation.

Fig. 7.—Lithotrite (Bigelow's).

It is not possible to describe here the many forms of other ordinary instruments of general surgery—probes, directors, scissors, forceps, and many more—nor those that are used in operations on the bones. Nor again can the numerous instruments used in special departments of surgery be discussed in detail. But, with regard to the special

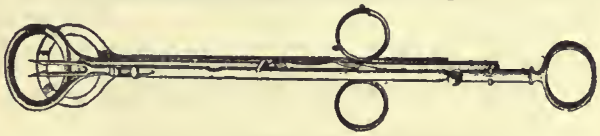

Fig. 8.—Tonsillotome (Mathieu's).

surgery of the eye, and of the throat and ear, it is to be noted that the chief advance in treatment arose from the invention of the present instruments of diagnosis, and that these are of comparatively recent date. The *opthalmoscope* was the work of Helmholtz. The *laryngoscope* was invented by Manuel Garcia in the middle of the

Fig. 9.—Ophthalmoscope (Landolt's).

19th century; and the use of a *frontal mirror*, for focussing a strong light on the membrana tympani, in the examination of the ear, was in use somewhat earlier. Before the ophthalmoscope it was impossible to study the internal diseases of the eye; before the laryngoscope the diseases of the larynx were invisible, and were mainly a matter of guess-work, and of vague and often futile treatment. Before the use of the frontal mirror the diseases of the ear were hardly studied, in that sense in which they are studied now. The wonderful advance of the special departments of surgery was, of course, the result of many forces, but one of the chief of these

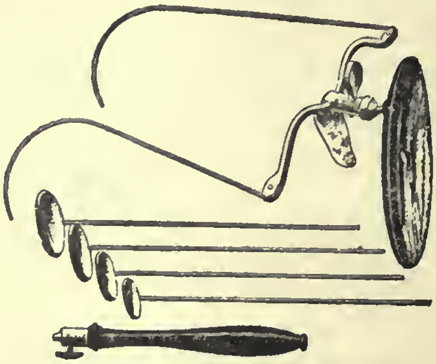

Fig. 10.—Laryngoscope (Lennox Browne's).

forces was the invention of proper instruments of diagnosis. The textbooks that were written immediately before those instruments became available were not far in advance of Ambroise Paré, so far as these special departments are concerned.

It may be well next to consider in what ways the conduct of an operation is influenced by those two great discoveries of anaesthetics, and the more gradual development of the principles of antiseptic and aseptic surgery; with special reference to the use of the instruments of surgery. The jubilee year of anaesthesia was 1896; the first use of nitrous oxide was on the 11th of December 1844; the first operation under ether was on the 30th of September 1846; the first use of chloroform was on the 4th of November 1847. The choice of the anaesthetic, or of some combination of anaesthetics, that is best suited to each particular case, is a matter of careful consideration; but, on the whole, the tendency in England is to keep to the *via media* between the more general use of chloroform in Scotland and the more general use of ether in the United States. Of the methods of administering chloroform there is no need to say much; by some

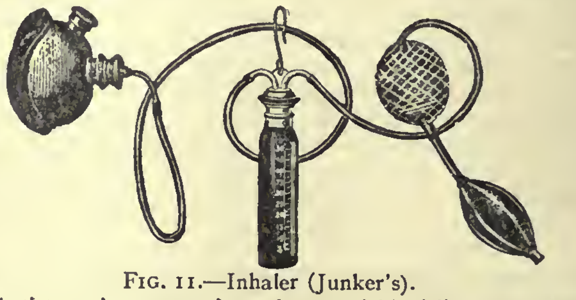

Fig. 11.—Inhaler (Junker's).

anaesthetists no instrument is used save a fold of lint or some such stuff, or a piece of flannel made into a sort of cone or mask. Use is generally made of a modification of "Junker's inhaler," whereby the vapour of chloroform is administered by means of a hand-ball. For the administration of ether some form of Clover's inhaler is generally used, whereby the ether in a small metal chamber passes as vapour into an indiarubber bag, and there is combined with the patient's breath in proportions determined by the anaesthetist throughout the operation. The metal chamber is so designed that by turning it the exact proportion of ether to air is fixed in accordance with the requirements of the case. Of late years, by the use of an iron cylinder of nitrous oxide, connected by a tube with a Clover's inhaler, it is possible to begin with nitrous oxide, and to go on, without interruption, with ether. More recently an admirable method has been devised of administering nitrous oxide with the admixture of air or of oxygen in such a way that the anaesthesia produced by the gas may be maintained for time enough to allow of an operation of some length.

Fig. 12.—Gas and Ether Apparatus (Hewitt's).

The series of discoveries which, in its application to surgery, has brought about the present antiseptic and aseptic methods of operation, is concerned both with the shape or use of the instruments of surgery and with their preparation for use. The mere sterilization, by boiling or by steaming, of all instruments and dressings, is enough to ensure their freedom from the ordinary micro-organisms of suppuration; but the surgeon cannot boil or steam either himself or his patient. The preparation, therefore, of the surgeon's hands, and of the skin over the area of operation, is made not only by scrubbing with soap and hot water, but by careful use of antiseptic lotions. Again, ligatures and sutures, which must be kept in stock ready for use, are kept, after careful sterilization, in antiseptic lotion, or are again sterilized immediately before an operation. Again, all towels used at an operation must be prepared, either by sterilization or by immersion in antiseptic lotion.

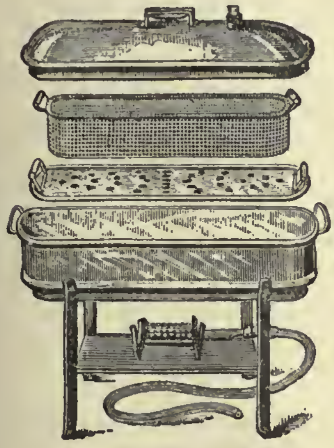

Fig. 13—Instrument Sterilizer.

The sterilization of all instruments and dressings is a simple matter: the usual sterilizer is a vessel like a fish-kettle, with a perforated metal tray in it, so that the instruments can be immersed in boiling water, and can be lifted on the tray and transferred straight from the sterilizer into vessels containing sterilized water or antiseptic lotion. For the sterilization of dressings an upper vessel is fitted to the sterilizer, so that the steam may permeate the dressings placed in it. In hospital practice it is used also to sterilize all towels, aprons and the like in a large cylindrical vessel. Sterilization by boiling or steaming, together with the use of antiseptic lotions, or of water that has been boiled, for all such things as cannot be boiled or steamed, is the essential principle of the surgery of the present day; and practically the antiseptic method and the aseptic method have become one, varying a little this way or that according to the nature and circumstances of the case.

Beside anaesthetics and antiseptics, there is a third series of discoveries that has profoundly influenced surgery—the use of the forces of electricity. The uses of electricity are fivefold.

1. *The Galvano-Cautery.*—The original form of the cautery, the *fer ardent* of Paré's time, for the arrest of haemorrhage after amputation, was a terrible affair. Happily for mankind, his invention of the ligature put an end to this use of the cautery, but it was still used in a small number of other cases. Subsequently Claude André Paquelin (b. 1836) invented a very ingenious form of cautery, a series of metal blades or points of different shapes and sizes, that could be fitted to a handle: these points were hollow inside, and were filled with fine platinum gauze, and, by means of a bottle and hand-bellows, they could be kept heated with benzene-vapour. Thus, when they had once been raised to a glowing heat by holding them over a spirit-lamp, they could be kept at any desired heat. This instrument is still in use for a few cases where very rapid and extensive cauterization is necessary. But for all finer use of actual heat the galvano-cautery alone is used—a series of very minute points of platinum, with a suitable trigger-handle, connected with a battery or (by means of a converter) with the ordinary house supply of electricity. In this way it is possible to apply a glowing point with a fineness and accuracy of adjustment that were wholly impossible with Paquelin's cautery.

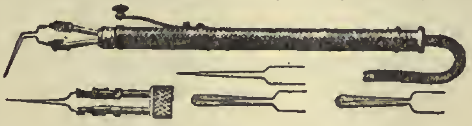

Fig. 14.—Galvano-cautery Set.

2. *Electrolysis.*—This method is of great value, in suitable cases, for the arrest or obliteration of small growths. The passage of the electric current between needles introduced into or under the skin brings about a gradual shrinking or cicatrization of the tissues subjected to it, without the production of any unsightly scar.

Fig. 15.—Electrolysis Needle-holders.

3. *Electro-Motor Power.*—During recent years the use of a small electro-motor machine has come into the practice of surgery for certain operations on the bones; especially for the operation for disease involving the mastoid bone. It is, of course, a better method for the use of a fine drill or burr, for example, than the "dental engine," where the power is generated by a pedal turning a wheel, and it will probably come into wide use both for dental surgery and for those operations of general surgery that require very gradual and delicate removal of small circumscribed areas of bone, especially of the cranial bones.

4. *The X-Rays.*—This, the most unexpected and, as it were, the most sensational discovery that has been bestowed on physicians and surgeons since the discovery of anaesthetics, is now used over a very wide and varied field of practice. Its value does not stop at the detection and localization of foreign bodies; indeed, this is but a small part of its work. It is used constantly for cases of actual or suspected fracture or dislocation; for cases of congenital or acquired

Fig. 16.—Cystoscope (Nitze's).

deformity; for cases involving difficulties of diagnosis between a swelling of the bone due to inflammation and a swelling due to a tumour; and for obscure cases of spinal disease, hip disease and the like. Moreover, it has been found possible, by Dr Hugh Walsham, and others to obtain pictures of the thoracic organs that are a very valuable guide in many obscure cases of disease of the lungs or of the pleura, and in many cases of thoracic aneurism or of intra-thoracic tumour. Every year the number and the range of the cases where the X-rays are helpful for diagnosis and for treatment become greater; and it is impossible to say at what point the surgical value of this discovery will find its limits. Beyond these uses, it is probable that the X-rays will maintain and extend the importance that they already have in the direct treatment of certain cases of disease of the skin (see X-Ray Treatment).

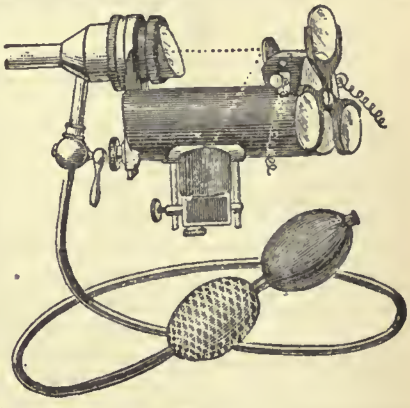

Fig. 17.—Urethroscope (Fenwick's), also used for ear, nose, throat, &c.

5. *The Electric Light.*—Beside the general superiority of this light to other lights for the routine work of surgery, there are several special uses for it. Of these, the most important is the *cystoscope*, a long narrow tube, shaped and curved somewhat like a catheter, and having at its end a very minute glow-lamp and reflector, and a small window. Its other end is fitted with a lens, and is connected by a switch with the main current. With this instrument, in skilled hands, it is possible to inspect the interior of the bladder, and in many cases to make an exact diagnosis under circumstances where otherwise it would be impossible. Another instance of the value of the electric lamp in diagnosis is given by the trans-illumination of the facial bones in cases of suspected disease of the central cavity of the superior maxillary bone. A small glow-lamp is held in the closed mouth, in a darkened room, and by a comparison of the shadows on the two sides of the face, thus trans-illuminated, an exact diagnosis can often be obtained as to the presence or absence of pus in this central cavity. Again, a small glow-lamp, duly sterilized, is often of great value in deep operations on the abdominal cavity.

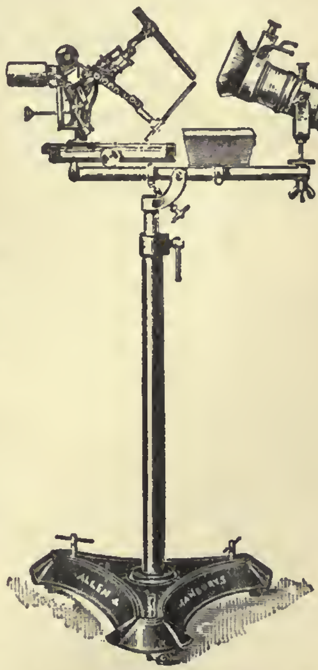

Fig. 18.—Finsen-Reyn Lamp.

The bactericidal properties of light have long been demonstrated by Bie and others. Professor Niels Finsen of Copenhagen first used the ultra-violet rays of solar light in the treatment of skin diseases.

notably of lupus. He later invented the lamp which bears his name. The original Finsen lamp comprised a voltaic arc of 60 to 80 amperes round which four tubes collected the light by quartz lenses, the light being cooled by passing through water and the tubes being surrounded by a water-jacket. The usual exposure was one hour. In the Finsen-Reyn modification now used, a single collecting tube fitted on an adjustable stand is placed in front of a scissors arc lamp consuming 20 amperes. The rays are cooled and water-jacketed as in the original. A suitable quartz compressor with a chamber containing circulating water is pressed upon the skin of the part to be treated and held at right angles to the impinging rays. The time of exposure is now reduced to forty-five minutes.

Radium when used in surgery is applied by means of applicators, either having the fixed salts on square or oblong metallic plates or cloths or by applicators having free radium in sealed metal tubes. These tubes are sometimes buried in the tissues. Sometimes a method of "screening" is adopted in order to modify the intensity of the radiation. This is done by enveloping the tubes containing

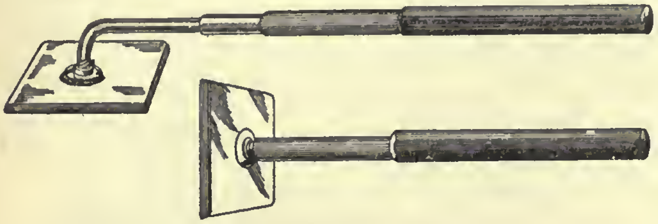

Fig. 19.—Radium Applicators.

the radium in cases of silver, lead or nickel of various thicknesses. In this, known as the method of Dr Dominici, the α and β rays are intercepted by the metal screens and the highly penetrative rays only applied to the morbid tissues.

The illustrations in this article are by permission of Messrs Allen & Hanbury, London, and that of the radium applicators by permission of Messrs Siemens Brothers, London.

SURICATE, or Meerkat (*Suricata tetradactyla*), a small South African mammal of the civet family, ranging from Cape Colony to Algoa Bay. The head and body are about 14 in. long, and the tail half as much; the fur is long and soft, light grizzled grey in colour, and banded with black on the lower part of the back. Meerkats are sociable animals, living in holes in the rocks on the mountains, and burrowing in the sandy soil of the plains. They form amusing pets, and in a wild state, writes Mrs A. Martin, they feed chiefly on "succulent bulbs, which they scratch up with the long, curved, black claws on their fore-feet. They are devoted sun-worshippers and in the early morning, before it is daylight, they emerge from their burrows and wait in rows till their divinity appears, when they bask joyfully in his beams."

SURINAM TOAD (*Pipa americana*), an aglossal tailless Batrachian, rendered famous by its mode of reproduction, first observed in 1710 by the Dutch anatomist F. Ruisch. It inhabits South America east of the Andes and north of the Amazons, and is thoroughly aquatic. In its extremely flattened head it is paralleled by two other vertebrates only, which, curiously, inhabit the same parts of South America, viz. the Silurid fish *Aspredo batrachus* and the Chelonian *Chelys matamata*; the end of the snout and the angles of the jaws bear several lappets, the fingers terminate in a star-shaped appendage, the toes are very broadly webbed and the eyes are minute and without lids.

The eggs are carried on the back by the mother, and the skin thickens and grows round the eggs until each is enclosed in a dermal cell, which is finally covered by a horny lid, believed to be formed by a secretion of the skin or else to represent the remains of the gelatinous capsule which at first surrounded the eggs. These, which may number about one hundred and measure five to seven millimetres in diameter, develop entirely within these pouches, and the young hop out in the perfect condition, without a vestige of a tail. Pairing takes place in the water, the male clasping the female round the waist. The way in which the eggs reach the back of the female has been observed in specimens kept in the London Zoological Gardens. During oviposition the cloaca projects from the vent as a bladder-like pouch, which is inverted forwards, between the back of the female and the breast of the male, and by means of this ovipositor the eggs are evenly distributed over the whole back How the eggs are fertilized has not been ascertained.

Authorities.—G. Grönberg and A. von Klinckowström, "Zur Anatomie der Pipa americana," *Zool. Jahrb. Anat.* vii. 609; A. D. Bartlett, "Note on the Breeding of the Surinam Water Toad," *Proc. Zool. Soc.* (1896), p. 595.

SURMA, or Barak, a river of Assam, India. It is one of the two chief rivers of the province, watering the southern valley as the Brahmaputra waters the northern and larger valley. It rises in the Barail range to the north of Manipur, its sources being among the southern spurs of Japvo. Thence its course is south with a slight westerly bearing, through the Manipur hills to British territory. The name of Barak is given to the upper part of the river, in Manipur and Cachar. A short distance below Badarpur in Cachar it divides into two branches. One of these, which passes Sylhet, is called Surma. The other is called Kusiara till it subdivides into (*a*) a branch called Bibiana or Kalni, which joins the Surma near Ajmiriganj, and (*b*) a branch which resumes the name of Barak and joins the Surma near Habiganj. At Bhairab Bazar in Mymensingh the Surma unites with the old Brahmaputra and becomes known as the Meghna. The river is navigable by steamers as far as Silchar in the rains. Total length about 560 m.

The Surma Valley and Hill Districts Division is a division of the province of Eastern Bengal and Assam. It includes the five districts of Sylhet Cachar, Lushai hills, Naga hills, and Khasi and Jaintia hills, with a total area of 25,481 sq. m. and a population in 1901 of 3,084,527.

SURPLICE (Late Lat. *superpelliceum*; Fr. *super*, over, and *pellis*, fur; Span. *sobrepellice*; Fr. *surplis*; in Ital. *cotta* and Ger. *Chorrock*, choir coat), a liturgical vestment of the Christian Church. It is a tunic of white linen or cotton material, with wide or moderately wide sleeves, reaching—according to the Roman use—barely to the hips and elsewhere in the churches of the Roman communion to the knee. It is usually decorated with lace, but in modern times—in Germany at least—also with embroidered bordures. The surplice originally reached to the feet, but as early as the 13th century it began to be shortened, though as late as the 15th century it still fell to the middle of the shin, and it was not till the 17th and 18th centuries that it was considerably shortened. More drastic were other modifications which it underwent in course of time in several localities, which led to the appearance of various subsidiary forms alongside of the original type. Such were the sleeveless surplice, which was provided at the sides with holes to put the arms through; the surplice with slit-up arms or lappels (so-called "wings") instead of sleeves; the surplice of which not only the sleeves but the body of the garment itself were slit up the sides, precisely like the modern dalmatic; and, finally, a sort of surplice in the form of a bell-shaped mantle, with a hole for the head, which necessitated the arms being stuck out under the hem. The first two of these forms were very early developed; and, in spite of their prohibition by synods here and there (*e.g.* that of Liége in 1287), they survive in various places to the present day. The latter two only appeared after the close of the middle ages: the first of them in South Germany, the second more especially in Venetia, where its use is attested by numerous pictorial records. As a rule, however, these subsidiary forms of surplice were worn mostly by the lower clergy. They were the result partly of the influence of the secular fashions, but more particularly of considerations of convenience.

The surplice belongs to the *vestes sacrae*, though it requires no benediction. It is proper to all clerics, even to those who have only received the tonsure, the bishop himself vesting with it those who have been newly tonsured by him. Its use in divine service is very varied. It is worn in choir at the solemn offices; it is the official sacral dress of the lower clergy in their liturgical functions; it is worn by the priest when administering the sacraments, undertaking benedictions, and the like; the use of the alb being nowadays almost exclusively confined to the mass and functions connected with this. In general it may be said that this was, in all main particulars, the custom so early as the 14th century.

The older history of the surplice is obscured by lack of exact information. Its name is derived, as Durandus and Gerland also affirm, from the fact that it was formerly put on over the fur garments which used to be worn in church and at divine service as a protection against the cold. It has been maintained that the surplice was known in the 5th century, the evidence being the garments worn by the two clerics in attendance on Bishop Maximian represented in the mosaics of S. Vitale at Ravenna; in this case, however, the dalmatic has been confused with the surplice. In all probability the surplice is no more than an expansion of the ordinary liturgical alb, due to the necessity for wearing it over thick furs. It is first mentioned in the 11th century, in a canon of the synod of Coyaca in Spain (1050) and in an ordinance of King Edward the Confessor. In Rome it was known at least as early as the 12th century. It probably originated outside Rome, and was imported thence into the Roman use. Originally only a choir vestment and peculiar to lower clergy, it gradually—certainly no later than the 13th century—replaced the alb as the vestment proper to the administering of the sacraments and other sacerdotal functions.

In the Oriental rites there is no surplice, nor any analogous vestment. Of the non-Roman Churches in the West the surplice has continued in regular use only in the Lutheran churches of Denmark, Norway and Sweden, and in the Church of England (see below). (J. Bra.)

Church of England.—The surplice was prescribed by the second Prayer-Book of Edward VI., as, with the tippet or the academical hood, the sole vestment of the minister of the church at "all times of their ministration," the rochet being practically regarded as the episcopal surplice. Its use was furiously assailed by the extremer Reformers but, in spite of their efforts, was retained by Elizabeth's Act of Uniformity, and enforced by the advertisements and injunctions issued under her authority, which ordered the "massing vestments"—chasubles, albs, stoles and the like—to be destroyed. It has since remained, with the exception of the cope (*q.v.*), the sole vestment authorized by law for the ministers, other than bishops, of the Church of England (for the question of the vestments prescribed by the "Ornaments Rubric" see Vestments). Its use has never been confined to clerks in holy orders, and it has been worn since the Reformation by all the "ministers" (including vicars-choral and choristers) of cathedral and collegiate churches, as well as by the fellows and scholars of colleges in chapel. The distinctive mark of the clergy (at least of the more dignified) has been the tippet or scarf above mentioned, a broad band of black silk worn stole-wise, but not to be confused with the stole, since it has no liturgical significance and was originally no more than part of the clerical outdoor dress (see Stole). The surplice was formerly only worn by the clergy when conducting the service, being exchanged during the sermon for the "black gown," *i.e.* either a Geneva gown or the gown of an academical degree. This custom has, however, as a result of the High Church movement, fallen almost completely obsolete. The "black gown," considered wrongly as the ensign of Low Church views, survives in comparatively few of even "evangelical" churches; it is still, however, the custom for preachers of university sermons to wear the gown of their degree.

The traditional form of the surplice in the Church of England is that which survived from pre-Reformation times, viz. a wide-sleeved, very full, plain, white linen tunic, pleated from the yoke, and reaching almost, or quite, to the feet. Towards the end of the 17th century, when large wigs came into fashion, it came for convenience to be constructed gown-wise, open down the front and buttoned at the neck, a fashion which still partially survives, notably at the universities. In general, however, the tendency has been, under continental influence, to curtail its proportions. The ample vestment with beautiful falling folds has thus in many churches given place to a scanty, unpleated garment scarce reaching to the knee. In the more "extreme" churches the surplices are frank imitations of the Roman *cotta.* (W. A. P.)

SURRENDER, in law, a mode of alienation of real estate. It is defined by Lord Coke to be "the yielding up of an estate for life or years to him that hath an immediate estate in reversion or remainder" (Coke upon Littleton, 337 b). It is the converse of release, which is a conveyance by the reversioner or remainderman to the tenant of the particular estate. A surrender is the usual means of effecting the alienation of copyholds. The surrender is made to the lord, who grants admittance to the purchaser, an entry of the surrender and admittance being made upon the court rolls. Formerly a devise of copyholds could only have been made by surrender to the use of the testator's will followed by admittance of the devisee. The Wills Act of 1837 now allows the devisee of copyholds without surrender, though admittance of the devisee is still necessary. A surrender must, since the Real Property Act 1845, be by deed, except in the case of copyholds and of surrender by operation of law. Surrender of the latter kind generally takes place by merger, that is, the combination of the greater and less estate by descent or other means without the act of the party (see Remainder). In Scots law surrender in the case of a lease is represented by renunciation. The nearest approach to surrender of a copyhold is resignation *in remanentiam* (to the lord) or resignation *in favorem* (to a purchaser). These modes of conveyance were practically superseded by the simpler forms introduced by the Conveyancing Act 1874.

SURRENTUM (mod. *Sorrento*, *q.v.*), an ancient town of Campania, Italy, situated on the N. side of the promontory which forms the S.E. extremity of the Bay of Naples. The legends indicate a close connexion between Lipara and Surrentum, as though the latter had been a colony of the former; and even through the Imperial period Surrentum remained largely Greek. Before the Roman supremacy it was one of the towns subject to Nuceria, and shared its fortunes up to the Social War; it seems to have joined in the revolt of 90 B.C. like Stabiae; and was reduced to obedience in the following year, when it seems to have received a colony. Its prosperity dates from the imperial period, when Capreae was a favourite residence of Augustus and Tiberius. Numerous sepulchral inscriptions of Imperial slaves and freedmen have been found at Surrentum. An inscription shows that Titus in the year after the earthquake of A.D. 79 restored the *horologium* of the town and its architectural decoration. A similar restoration of an unknown building in Naples in the same year is recorded in an inscription from the last-named town (cf. A. Sogliano in *Notizie degli Scavi*, 1901, p. 363). The most important temples of Surrentum were those of Athena and of the Sirens (the latter the only one in the Greek world in historic times); the former gave its name to the promontory. In antiquity Surrentum was famous for its wine (oranges and lemons which are now so much cultivated there not having been introduced into Italy in antiquity), its fish, and its red Campanian vases; the discovery of coins of Massilia, Gaul and the Balearic Islands here indicates the extensive trade which it carried on. The position of Surrentum was very secure, it being protected by deep gorges, except for a distance of 300 yds. on the south-west where it was defended by walls, the line of which is necessarily followed by those of the modern town. The arrangement of the modern streets preserves that of the ancient town, and the disposition of the walled paths which divide the plain to the east seems to date in like manner from Roman times. No ruins are now preserved in the town itself, but there are many remains in the villa quarter to the east of the town on the road to Stabiae, of which traces still exist, running much higher than the modern road, across the mountain; the site of one of the largest (possibly belonging to the Imperial house) is now occupied by the Hotel Victoria, under the terrace of which a small theatre was found in 1855; an ancient rock-cut tunnel descends hence to the shore. Remains of other villas may be seen, but the most important ruin is the reservoir of the (subterranean) aqueducts just outside the town on the east, which had no less than twenty-seven chambers each about 90 ft. by 20 ft. Greek and Oscan tombs have also been found. Another suburb lay below the town and on the promontory on the west of it; under the Hotel Sirena are substructions and a rock-hewn tunnel. To the north-west on the Capo di Sorrento is another villa, the so-called Bagni della Regina Giovanna, with baths, and in the bay to the south-west was the villa of Pollius Felix, the friend of Statius, which he describes in *Silvae* ii. 2, of which remains still exist. Farther west again are villas, as far as the temple of Athena on the promontory named after her at the extremity of the peninsula (now Punta Campanella). Neither of this nor of the famous temple of the Sirens are any traces existing.

See J. Beloch, *Campanien*, p. 252 sqq. (2nd ed., Breslau, 1890). (T. As.)

SURREY, EARLDOM OF. There is some doubt as to when this earldom was created, but it is unquestionably of early origin. A Norman count, William de Warenne (*c.* 1030–1088), is generally regarded as its first holder and is thought to have been made an earl by William II. about 1088. William and his successors were styled earls of Surrey or Earls Warenne indifferently, and the family became extinct when William, the 3rd earl, died in 1148. The second family to hold the earldom of Surrey was descended from Isabel de Warenne (d. 1199), daughter and heiress of Earl William, and her second husband Hamelin Plantagenet (d. 1202), an illegitimate half-brother of King Henry II. Hamelin took the name of Warenne and was recognized as earl of Surrey or Earl Warenne, and his descendants held the earldom until Earl John died without legitimate issue in 1347.

The earldom and estates of the Warennes now passed to John's nephew, Richard Fitzalan, earl of Arundel (*c.* 1307–1376), being forfeited when Richard's son, Richard, was beheaded for treason in 1397. Then for about two years there was a duke of Surrey, the title being borne by Thomas Holand, earl of Kent (1374–1400), from 1397 until his degradation in 1399. In 1400 Richard Fitzalan's son, Sir Thomas Fitzalan (1381–1415), was restored to his father's honours and became earl of Arundel and earl of Surrey, but the latter earldom reverted to the Crown when he died. In 1451 John Mowbray (1444–1476), afterwards duke of Norfolk, was created earl of Surrey, but the title became extinct on his death.

The long connexion of the Howards with the earldom of Surrey began in 1483 when Thomas Howard, afterwards duke of Norfolk, was created earl of Surrey. Since that time, with the exception of brief periods when some of its holders were under attainder, the title has been borne by the duke of Norfolk. The courtesy title of the duke's eldest son is earl of Surrey.

See the articles WARENNE, EARLS; and ARUNDEL, EARLS OF; also G. E. C.(okayne), *Complete Peerage*, vol. vii. (1896).

SURREY, HENRY HOWARD, EARL OF (1518?–1547), English poet, son of Lord Thomas Howard, afterwards 3rd duke of Norfolk, and his wife Elizabeth Stafford, daughter of the duke of Buckingham, was born probably in 1518.[1] He succeeded to the courtesy title of earl of Surrey in 1524, when his father became duke of Norfolk. His early years were spent in the various houses belonging to the Howards, chiefly at Kenninghall, Norfolk. He had as tutor John Clerke, who, beside instructing him in the classics, inculcated a great admiration for Italian literature. The duke of Norfolk was proud of his son's attainments (Chapuys to the emperor, December 9, 1529). The duke was governor of Henry Fitzroy, duke of Richmond, the natural son of Henry VIII. and Elizabeth Blount. Surrey was a little more than a year older than Fitzroy, and became his companion and friend. Fitzroy was at Windsor from 1530 to 1532, and it must be to these years that Surrey refers in the lines written in prison at Windsor, "where I, in lust and joy, with a king's son, my childish years did pass." Anne Boleyn tried to arrange a marriage between the princess Mary and her kinsman, Surrey. The Spanish ambassador, in the hope of detaching the duke of Norfolk's interest from Anne Boleyn in favour of Catherine of Aragon, seems to have been inclined to favour the project; but Anne changed her mind, and as early as October 1530 arranged a marriage for Surrey with Lady Frances de Vere, daughter of the 15th earl of Oxford. This was concluded at the earliest possible date, in February 1532, but in consequence of the extreme youth of the contracting parties, Frances did not join her husband until 1535. In October Surrey accompanied Henry VIII. to Boulogne to meet Francis I., and, rejoining the duke of Richmond at Calais, he proceeded with him to the French court, where the two Englishmen were lodged with the French royal princes. Surrey created for himself a reputation for wisdom, soberness and good learning, which seems curious in view of the events of his later life. Meanwhile in spite of his marriage with Frances de Vere, the project of a contract between him and the princess Mary was revived in a correspondence between Pope Clement VII. and the emperor Charles V., but definitely rejected by the latter. Surrey only returned to England in the autumn of 1533, when the duke of Richmond was recalled to marry his friend's sister, Mary Howard. Surrey made his home at his father's house of Kenninghall, and here was a witness of the final separation between his parents, due to the duke's relations with Elizabeth Holland, who had been employed in the Howards' nursery. Surrey took his father's side in the family disputes, and remained at Kenninghall, where his wife joined him in 1535. In May 1536 he filled his father's functions of earl marshal at the trial of his cousins Anne Boleyn and Lord Rochford. In the autumn of that year he took part with his father in the bloodless campaign against the rebels in Yorkshire and Lincolnshire, in the "Pilgrimage of Grace." Although he had supported the royal cause, insinuations were made that he secretly favoured the insurgents. Hasty in temper, and by no means friendly to the Seymour faction at court, he struck a man who repeated the accusation in the park at Hampton Court. For breaking the peace in the king's domain he was arrested (1537), but thanks to Cromwell, who had yielded to the petition of the young man's father, he was not compelled to appear before the privy council, but was merely sent to reside for a time at Windsor. During this imprisonment and the subsequent retirement at Kenninghall, he had leisure to devote himself to poetry. In 1539 he was again received into favour. In May 1540 he was one of the champions in the jousts celebrated at court. The fall of Thomas Cromwell a month later increased the power of the Howards, and in August Henry VIII. married Surrey's cousin, Catherine Howard. Surrey was knighted early in 1541, and soon after he received the order of the Garter, was made chancellor of the duchy of Lancaster, and, in conjunction with his father, grand seneschal of the university of Cambridge. He apparently preserved the royal favour after the execution of Catherine Howard (at which he was present), for in December 1541 he received the grant of certain manors in Norfolk and Suffolk. In 1542 he was imprisoned in the Fleet for a quarrel with a certain John Leigh, but on appeal to the privy council he was sent to Windsor Castle, and, after being bound over to keep the peace with John Leigh under a penalty of 10,000 marks, he was soon liberated. Shortly after his release he joined his father on the Scottish expedition. They laid waste the country, but retreated before the earl of Huntly, taking no part in the victorious operations that led up to Solway Moss. To this year no doubt belong the poems in memory of Sir Thomas Wyat. His ties with Wyat, who was fifteen years his elder and of opposite politics, seem to have been rather literary than personal. He appears to have entered into closer relations with the younger Wyat. In company with "Mr Wyat," he amused himself by breaking the windows of the citizens of London on the 2nd of February 1543. For this he was accused by the privy council, a second charge being that he had eaten meat in Lent. In prison probably he wrote the satire on the city of London, in which he explains his escapade by a desire to rouse Londoners to a sense of their wickedness. In October he joined the English army co-operating with the imperial forces in Flanders, and on his return in the next month brought with him a letter of high commendation from Charles V. In the campaign of the next year he served as field marshal under his

[1] The only authority for the date of his birth is the legend *Sat. superest. Aetatis XXIX.* on a portrait of Henry Howard at Arundel Castle.

father, and took part in the unsuccessful siege of Montreuil. In August 1545 he was sent to the relief of Edward Poynings, then in command of Boulogne, and was made lieutenant-general of the English possessions on the Continent and governor of Boulogne. Here he gained considerable successes, and insisted on the retention of the town in spite of the desire of the privy council that it should be surrendered to France. A reverse on the 7th of January at St Étienne was followed by a period of inaction, and in March Surrey was recalled.

Surrey had always been an enemy to the Seymours, whom he regarded as upstarts, and when his sister, the duchess of Richmond, seemed disposed to accept a marriage with Sir Thomas Seymour, he wrote to her insinuating that this was a step towards becoming the mistress of Henry VIII. By his action in thwarting this plan he increased the enmity of the Seymours and added his sister to the already long list of the enemies which he had made by his haughty manner and brutal frankness. He was now accused of quartering with his own the arms of Edward the Confessor, a proceeding which, it was alleged, was only permissible for the heir to the crown. The details of this accusation were false; moreover, Surrey had long quartered the royal arms with his own without offence. The charge was a pretext covering graver suspicions. Surrey had asserted in the presence of a certain George Blage, who was inclined to the reforming movement, that on Henry's death, his father, the duke of Norfolk, as the premier duke in England, had the obvious right of acting as regent to Prince Edward. He also boasted of what he would do when his father had attained that position. All of this was construed into a plot on the part of his father and himself to murder the king and the prince. The duke of Norfolk and his son were sent to the Tower on the 12th of December 1546. Every effort was made to secure evidence. The duchess of Richmond was one of the witnesses (see her depositions in Herbert of Cherbury, *Life and Reign of Henry VIII.*, 1649) against her brother, but her statements were too doubtful to add anything to the formal indictment. On the 13th of January 1547 Surrey defended himself at the guildhall on the charge of high treason for having illegally made use of the arms of Edward the Confessor, before judges selected for their known hatred of himself. He was condemned by a jury, packed for the occasion, to be hanged, drawn and quartered at Tyburn. This sentence was not carried out. Surrey was beheaded on Tower Hill on the 19th of the month, and was buried in the church of All Saints, Barking. His remains were afterwards removed by his son the earl of Northampton to Framlingham, Suffolk. His father, who was charged with complicity in his son's crime, was, as a peer of the realm, not amenable to a common jury. The consequent delay saved his life. He was imprisoned during the whole of the reign of Edward VI., but on Mary's accession he was set free, by an act which also assured the right of the Howards, as descendants of the Mowbray family, to bear the arms of the Confessor.

Surrey's name has been long connected with the "Fair Geraldine," to whom his love poems were supposed to be addressed. The story is founded on the romantic fiction of Thomas Nashe, *The Unfortunate Traveller, or Life of Jack Wilton* (1594), according to which Surrey saw in a magic glass in the Netherlands the face of Geraldine, and then travelled throughout Europe challenging all comers to deny in full field the charms of the lady. At Florence he held a tournament in her honour, and was to do the same in other Italian cities when he was recalled by order of Henry VIII. The legend, deprived of its more glaring discrepancies with Surrey's life, was revived in Michael Drayton's *Englands Heroicall Epistles* (1598). Geraldine was the daughter of the earl of Kildare, Lady Elizabeth Fitzgerald, who was brought up at the English court in company with the princess Elizabeth (see James Graves, a *Brief Memoir of Lady Elizabeth Fitzgerald*, 1874). She was ten years old when in 1537 Surrey addressed to her the sonnet "From Tuskane came my ladies worthy race," and nothing more than a passing admiration of the child and an imaginative anticipation of her beauty can be attributed to Surrey. "A Song . . . to a ladie that refused to daunce with him," is addressed to Lady Hertford, wife of his bitter enemy, and the two poems, "O happy dames" and "Good ladies, ye that have your pleasures in exile," are addressed to his wife, to whom, at any rate in his later years, he seems to have been sincerely attached.

His poems, which were the occupation of the leisure moments of his short and crowded life, were first printed in *Songs and Sonettes written by the ryght honorable Lorde Henry Howard late Earle of Surrey, and other* (apud Richardum Tottel, 1557). A second edition followed in July 1557, and others in 1559, 1565, 1567, 1574, 1585 and 1587. Although Surrey's name, probably because of his rank, stands first on the title-page, Wyat was the earlier in point of time of Henry's "courtly makers." Surrey, indeed, expressly acknowledges Wyat as his master in poetry. As their poems appeared in one volume, long after the death of both, their names will always be closely associated. Wyat possessed strong individuality, which found expression in rugged, forceful verse. Surrey's contributions are distinguished by their impetuous eloquence and sweetness. He revived the principles of Chaucer's versification, which his predecessors had failed to grasp, perhaps because the value of the final *e* was lost. He introduced new smoothness and fluency into English verse. He never allowed the accent to fall on a weak syllable, nor did he permit weak syllables as rhymes. His chief innovation as a metrician lies outside the *Miscellany*. His translation of the second and fourth books of the *Aeneid* into blank verse—the first attempt at blank verse in English—was published separately by Tottel in the same year with the title of *Certain Bokes of Virgiles Aeneis turned into English meter*. It has been suggested that in this matter Surrey was influenced by the translation of Virgil published at Venice by Ippolito de' Medici in 1541, but there is no direct evidence that such was the case. His sonnets are in various schemes of verse, and are less correct in form and more loosely constructed than those of Wyat. They commonly consist of three quatrains with independent rhymes, terminating with a rhyming couplet. But his sonnets, his elegy on the death of Wyat, his lover's complaint cast in pastoral form, and his lyrics in various measures, served as models to more than one generation of court poets. Both in form and substance Surrey and his fellow poets were largely indebted to Italian predecessors; most of his poems are in fact adaptations from Italian originals. The tone of the love sentiment was new in English poetry, very different in its earnestness, passion and fantastic extravagance from the lightness and gaiety of the Chaucerian school.

See Professor E. Arber's reprint of *Songs and Sonettes* (*English Reprints*, 1870); the Roxburghe Club reprint of *Certain Bokes of Virgiles Aeneis* (1814); Dr G. F. Nott, *The Works of Henry Howard, Earl of Surrey* (1815); and *The Poetical Works of Henry Howard, Earl of Surrey* (Aldine edition, 1866). The best account of Surrey's life is in Edmond Bapst's *Deux Gentilhommes-poètes de la cour de Henry VIII.* (1891), which rectifies Dr Nott's memoir in many points. See also Brewer and Gairdner, *Letters and State Papers of Henry VIII.*; Lord Herbert of Cherbury, *Life and Raigne of Kinge Henry the Eighth* (1649); J. A. Froude, *History of England* (chs. xxi. and xxii.); W. J. Courthope, *History of English Poetry* (1897), vol. ii. ch. iii., where the extent and value of Surrey's innovations in English poetry are estimated; F. M. Padelford, *The MS. Poems of Henry Howard, Earl of Surrey* (1906); O. Fest, "Über Surreys Virgilübersetzung," in *Palästra*, vol. xxxiv. (Berlin, 1903).

SURREY, a south-eastern county of England bounded N. by the Thames, separating it from Buckinghamshire and Middlesex, E. by Kent, S. by Sussex, and W. by Hampshire and Berkshire. The administrative county of London bounds that of Surrey (south of the Thames) on the north-east. The area is 758 sq. m. The north Downs are a picturesque line of hills running east and west through the county somewhat south of the centre (see Downs). Leith Hill, south-west of Dorking (965 ft.), is the highest summit, and commands a prospect unrivalled in the south of England; Holmbury Hill close by reaches 857 ft., and the detached summit of Hindhead above Haslemere in the south-west reaches 895 ft. At Guildford the Wey breaches the hills; and at Dorking the Mole. These are the chief rivers of the county; they reach the Thames near Weybridge and at East Molesey respectively. The Wandle is a smaller tributary in the north-east of the county. Surrey is thus almost entirely in the Thames basin. In the south-east it includes headstreams of the Eden, a tributary of the Medway; and in the south a small area drains to the English channel. Three types of scenery appear—that of the hilly southern district; that of the Thames, with its richly-wooded banks; and, in the north-west, that of the sandy heath-covered district, abundant in conifers, which includes the healthy open tracts of Bagshot Heath and other commons, extending into Berkshire and Hampshire. Possessing these varied attractions, Surrey has become practically a great residential district for those who must live in the neighbourhood of London.

Geology.—The northern portion of the county, in the London basin, belongs to the Eocene formation: the lower ground is occupied chiefly by the London Clay of the Lower Eocene, stretching (with interruptions) from London to Farnham; this is fringed on its southern edge by the underlying Woolwich beds of the same group, which also appear in isolated patches at Headley near Leatherhead; and the Thanet Sands at the base crop out between Beddington, Banstead and Leatherhead. The north-western portion of the county, covered chiefly by heath and Scotch fir, belongs to the Upper Eocene, Bagshot Sands: the Fox hills and the bleak Chobham Ridges are formed of the upper series of the group, which rests upon the middle beds occupying the greater part of Bagshot Heath and Bisley and Pirbright commons, while eastwards the commons of Chobham, Woking and Esher belong to the lower division of the group. To the south of the Eocene formations the smooth rounded outlines of the chalk hills extend through the centre of the county from Farnham to Westerham (Kent). From Farnham to Guildford they form a narrow ridge called the Hog's Back, about half a mile in breadth with a higher northern dip, the greatest elevation reached in this section being 505 ft. East of Guildford the northern dip decreases and the outcrop widens, throwing out picturesque summits, frequently partly wooded, and commanding wide and beautiful views over the Weald. The Upper Greensand, locally known as firestone, and quarried and mined for this purpose and for hearthstone near Godstone, crops out underneath the Chalk along the southern escarpment of the Downs. The Gault, a dark blue sandy clay, rests beneath the Upper Greensand in the bottom of the long narrow valley which separates the chalk Downs from the well-marked Lower Greensand hills. The Lower Greensand includes the subordinate divisions known as the Folkestone Sands, exploited near Godstone for commercial purposes; the Sandgate beds, to which the well-known fuller's earth of Nutfield belongs, and the Hythe beds, which contain the Kentish Rag, a sandy glauconitic limestone used for road repairs and building; also a hard, conglomeratic phase of this series locally called Bargate stone. To this formation belong the heights of Leith Hill, Hindhead and the Devil's Punchbowl, Holmbury Hill. Between the Lower Greensand and the Weald Clay is a narrow inconspicuous belt of Atherfield Clay. The Weald Clay itself consists of a blue or brown shaly clay, amid which are deposited river shells, plants of tropical origin and reptilian remains. The lower portion of the Wealden series, the Hastings Sands, occupy a small area in the south-eastern corner of the county. Bordering the Thames there are terraced deposits of gravel and loam.

Agriculture.—Between one-half and three-fifths of the area of the county, a low proportion, is under cultivation, and of this about five-ninths is in permanent pasture. There are considerable varieties of soil, ranging from plastic clay to calcareous earth and bare rocky heath. The plastic clay is well adapted for wheat, but oats are the most largely grown of the decreasing grain crops. A considerable area is occupied by market gardens on the alluvial soil along the banks of the Thames, especially in the vicinity of London. In early times the market gardeners were Flemings, who introduced the culture of asparagus at Battersea and of carrots at Chertsey. Rhododendrons and azaleas are largely grown in the north-western district of the county. In the neighbourhood of Mitcham various medicinal plants are cultivated, such as lavender, mint, camomile, anise, rosemary, liquorice, hyssop, &c. The calcareous soil in the neighbourhood of Farnham is well adapted for hops, but this crop in Surrey is of minor importance. There is a large area under wood. Oak, chestnut, walnut, ash and elm are extensively planted; alder and willow plantations are common; and the Scotch fir propagates naturally from seed on the commons in the north-west. The extent of pasture land is not great, with the exception of the Downs, which are chiefly occupied as sheep-runs. Dairy-farming is a more important industry than cattle-feeding, large quantities of milk being sent to London.

Manufactures and Communications.—The more important manufactures are chiefly confined to London and its immediate neighbourhood. The rivers Mole and Wandle, however, supply power for a variety of manufactures, such as oil, paper and sheet-iron mills. Communications include the navigation of the Thames and Wey, and the Basingstoke canal, communicating with the Wey from Frimley and Woking. Owing to its proximity to London the county is served by many lines of railway, the companies being the London & South-Western, the London Brighton & South Coast and the South-Eastern & Chatham.

Population and Administration.—The area of the ancient county is 485,122 acres, with a population in 1901 of 2,012,744. The population in 1801 was 268,233, and in 1851, 683,082; and it nearly doubled between 1871 and 1901. Under the provisions of the Local Government Act 1888, part of the county was transferred to the county of London. Thus the area of the ancient county, extra-metropolitan, is 461,999 acres, with a population in 1901 of 675,774. The area of the administrative county is 461,807 acres. The county contains 14 hundreds. Croydon (pop. 133,895) is a county borough, and the other municipal boroughs are Godalming (8748), Guildford (15,938), Kingston (34,375), Reigate (25,993), Richmond (31,672), Wimbledon (41,652). The following are urban districts: Barnes (17,821), Carshalton (6746), Caterham (9486), Chertsey (12,762), Dorking (7670), East and West Molesey (6034), Egham (10,187), Epsom (10,915), Esher and The Dittons (9489), Farnham (6124), Frimley (8409), Ham (1460), Leatherhead (4964), The Maldens and Coombe (6233), Surbiton (15,017), Sutton (17,223), Walton-on-Thames (10,329), Weybridge (5329), Woking (16,244). There are six parliamentary divisions—North Western or Chertsey, Mid or Epsom, Kingston, North Eastern or Wimbledon, South Eastern or Reigate, South Western or Guildford; each returning one member. The borough of Croydon returns one member. Surrey is in the south-eastern circuit, and assizes are held at Guildford and Kingston alternately. The administrative county has one court of quarter sessions, and is divided into eleven petty sessional divisions. The boroughs of Croydon, Godalming, Guildford, Kingston, Reigate and Richmond have separate commissions of the peace, and Croydon and Guildford have in addition separate courts of quarter sessions. The central criminal court has jurisdiction over certain parishes adjacent to London. All those civil parishes within the county of Surrey, of which any part is within 12 m. of, or of which no part is more than 15 m. from, Charing Cross, are in the metropolitan police district. The total number of civil parishes is 144. The ancient county contains 230 ecclesiastical parishes or districts, wholly or in part situated in the dioceses of Rochester, Winchester, Canterbury, Oxford and Chichester.

History.—The early history of this district is somewhat uncertain. Ethelwerd, in the Anglo-Saxon Chronicle for 823, places it in the "Medii Angli" or "Medii Saxones." Its position between the Weald and the Thames decided its northern and southern borders, and the Kentish boundary probably dates from the battle of Wibbandune between Ethelbert of Kent and Ceawlin of Wessex, which traditionally took place at Wimbledon, though this is disputed. The western border, like the southern, was a wild uncultivated district; no settled boundary probably existing at the time of the Domesday Survey. The number of hundreds at that time was fourteen as now, but the hundred of Farnham was not so called, the lands of the bishop of Winchester being placed in no hundred, but coinciding with the present hundred of that name. There is no record of Surrey ever having been in any diocese but Winchester, of which it was an archdeaconry in the 12th century. At the time of the Domesday Survey there were four deaneries: Croydon, Southwark, Guildford and Ewell. Croydon was a peculiar of Canterbury, in which diocese it was included in 1291. In the time of Henry VIII., Croydon was comprehended in the deanery of Ewell, some of its rectories being included in the deanery of Southwark. The old deanery of Guildford was included in the modern one of Stoke. In 1877, Southwark, with some parishes, was transferred to the diocese of Rochester. In the 7th century Surrey was under the overlordship of Wulfhere, king of Mercia, who founded Chertsey abbey, but in 823, when the Mercians were defeated by Egbert of Wessex, it was included in the kingdom of Wessex, as the Anglo-Saxon Chronicle relates.

Surrey was constantly overrun by Danish hordes in the 9th century and until peace was established by the accession of Canute. In 857 a great national victory over the Danes took place at Ockley near Leith Hill. Surrey is not of great historical importance, except its northern border, the southern part having been forest and waste land, long uninhabited and almost impassable for an army. Guildford, though the county town, and often the seat of the court under John and Henry III., was of little importance beside Southwark, the centre of trade and commerce, the residence of many ecclesiastical dignitaries, a frequent point of attack on London, and a centre for rebellions and riots. The Norman army traversed and ravaged the county in their march on London, a large portion of the county having been in the hands of Edward and Harold, fell to the share of William himself; his most important tenants in chief being Odo of Bayeux and Richard de Tonebridge, son of Count Gilbert, afterwards "de Clare." The church also had large possessions in the county, the abbey of Chertsey being the largest monastic house. Besides these private jurisdictions, there were the large royal parks and forests, with their special jurisdiction. The shire court was almost certainly held at Guildford, where the gaol for both Sussex and Surrey was from as early as 1202 until 1487, when Sussex had its own gaol at Lewes. The houses of Warenne and de Clare were long the two great rival influences in the county; their seats at Reigate and Blechingley being represented in parliament from the time of Edward I. till the Reform bills of the 19th century. At the time of the Barons' Wars their influence was divided—de Clare marching with Montfort, and de Warenne supporting the king. In the Peasants' Rising of 1381, and during Jack Cade's Rebellion in the next century, Southwark was invaded, the prisons broken open and the bridge into London crossed. London was unsuccessfully attacked from the Surrey side in the Wars of the Roses; and was held for three days and pillaged during a rising of the southern counties under Mary. During the fears of invasions from Spain, levies were held in readiness in Surrey to protect London; and it was an even more important bulwark of London in the Civil War, on account of the powder mills at Chilworth and the cannon foundries of the Weald. In common with the south-eastern district generally, Surrey was parliamentarian in its sympathies. Sir Richard Onslow and Sir Poynings More were the most prominent local leaders. Farnham Castle and Kingston, with its bridge, were several times taken and held during the war by the opposing parties, and in the later part of the war, when the parliament and army were treating, three of the line of forts defending London were on the Surrey side, from which the army entered London.

The last serious skirmish south of the Thames took place near Ewell and Kingston, where the earl of Holland and a body of the Royalists were routed. This was the last real fighting in the county, though it was often a centre of riots; the most serious being those of 1830, and of the Chartists in 1848, who chose Kennington Common as their meeting-place. The Mores of Loseley and the Onslows were among the most famous county families under the Tudors, as at the time of the Civil War; the Onslows being even better known later in the person of Sir Arthur Onslow, Speaker of the House under George I.

The earliest industries in Surrey were agricultural. The stone quarries of Limpsfield and the chalk of the Downs were early used, the latter chiefly for lime-making. Fuller's earth was obtained from Reigate and Nutfield; and the facilities afforded by many small streams, and the excellent sheep pasture, made it of importance in the manufacture of cloth, of which Guildford was a centre. Glass and iron were made in the Weald district, whose forests produced the necessary charcoal for smelting. Chiddingfold is mentioned in 1266 for its glass-making, and was one of the chief glass-producing districts in late Tudor times. The ironworks of Surrey were of less importance, and much later in development than those of Kent and Sussex, owing to the want of good roads or waterways, but the increasing demand for ordnance in the 16th century led to the spread of the industry northward; the most considerable works in Surrey being those of Viscount Montague at Haslemere. Chilworth, which was famous for its powder mills in the 16th century, remains a seat of the industry. Southwark and its neighbourhood early became a suburb of London and a centre of trades which were crowded out of London. The earliest Delft ware manufactory in England was at Lambeth, which maintains its fame as a centre of earthenware manufacture. The beautiful encaustic tiles of Chertsey Abbey are thought to have been made in English monasteries and date from the 13th century. Although the county was doubtless represented in the representative councils of the reign of Henry III., the first extant returns of two knights of the shire are for the parliament of 1290. The Reform Bill of 1832 gave Surrey four members; dividing the county into east and west divisions. Several boroughs were disfranchized then and in 1867, when East Surrey was again divided into east and mid divisions, on account of the growth of London suburbs, two more members being added at the same time. In 1855 all old boroughs and divisions were superseded; the county being divided into the electoral divisions of Chertsey, Guildford, Reigate, Epsom, Kingston and Wimbledon, each returning one member. Finally, in 1888, the new county of London annexed large portions of Surrey along the northern border.

Antiquities.—The only ecclesiastical ruins worthy of special mention are the picturesque walls of Newark Priory, near Woking, founded for Augustinians in the time of Richard Cœur de Lion; and the Early English crypt and part of the refectory of Waverley Abbey, the earliest house of the Cistercians in England, founded in 1128. The church architecture is of a very varied kind, and has no peculiarly special features. Among the more interesting churches are Albury (the old church), near Guildford, the tower of which is of Saxon or very early Norman date; Beddington, a fine example of Perpendicular, containing monuments of the Carew family; Chaldon, remarkable for its fresco wall-paintings of the 12th century, discovered during restoration in 1870; Compton, which, though mentioned in Domesday, possesses little of its original architecture, but is worthy of notice for its two-storeyed chancel and its carved wooden balustrade surmounting the pointed transitional Norman arch which separates the nave from the chancel; Leigh, Perpendicular, possessing some very fine brasses of the 15th century; Lingfield, Perpendicular, containing ancient tombs and brasses of the Cobhams, and some fine stalls (the church was formerly collegiate); Ockham, chiefly Decorated, with a lofty embattled tower, containing the mausoleum of Lord Chancellor King (d. 1734), with full-length statue of the chancellor by Rysbrack; Stoke d'Abernon, Early English, with the earliest extant English brass, that of Sir John d'Abernon, 1277, and other fine examples. Churches at Guildford, Reigate and Woking are also noteworthy. Of old castles the only examples are Farnham, occupied as a palace by the bishops of Winchester, originally built by Henry of Blois, and restored by Henry III.; and Guildford, with a strong quadrangular Norman keep. Of ancient domestic architecture examples include Beddington Hall (now a female orphan asylum), the ancient mansion of the Carews, rebuilt in the reign of Queen Anne, and in modern times, but retaining the hall of the Elizabethan building; Crowhurst Place, built in the time of Henry VII., the ancient seat of the Gaynesfords, and frequently visited by Henry VIII.; portions of Croydon Palace, an ancient seat of the archbishops of Canterbury; the gate tower of Esher Place, built by William of Waynflete, bishop of Winchester, and repaired by Cardinal Wolsey; Archbishop Abbot's hospital, Guildford, in the Tudor style; the fine Elizabethan house of Loseley near Guildford; Smallfield Place near Reigate, now a farmhouse, once the seat of Sir Edward Bysshe (*c.* 1615–1679), garter king-at-arms; Sutton Place near Woking, dating from the time of Henry VIII., possessing curious mouldings and ornaments in terra-cotta; and Ham House, of red brick, dating from 1610.

See Topley's *Geology of the Weald* and Whitaker's *Geology of London Basin*, forming part of the *Memoirs of Geological Survey of United Kingdom* (London, 1875); J. Aubrey, *Natural History and Antiquities of Surrey* (5 vols., London, 1718–1719); D. Lysons, *Environs of London* (5 vols., London, 1800–1811); Baxter, *Domesday Book of Surrey* (1876); O. Manning and W. Bray, *History and Antiquities of Surrey* (3 vols., London, 1804–1814); E. W. Brayley, *Topographical History of Surrey* (5 vols., London, 1841–1848); another edition, revised by E. Walford (London, 1878); *Archaeological Collections* (Surrey Archaeological Society; London, from 1858); Eric Parker, *Highways and Byways in Surrey* (London, 1908).

SURROGATE (from Lat. *surrogare*, to substitute for), a deputy of a bishop or an ecclesiastical judge, acting in the absence of his principal and strictly bound by the authority of the latter. Canon 128 of the canons of 1603 lays down the qualifications necessary for the office of surrogate and canon 123 the regulations for the appointment to the office. At present the chief duty of a surrogate in England is the granting of marriage licences, but judgments of the arches court of Canterbury have been delivered by a surrogate in the absence of the official principal. The office is unknown in Scotland, but is of some importance in the United States as denoting the judge to whom the jurisdiction of the probate of wills, the grant of administration and of guardianship is confided. In some states he is termed surrogate, in others judge of probate, register, judge of the orphans' court, &c. His jurisdiction is local, being limited to his county.

SURTEES, ROBERT (1779–1834), English antiquary and topographical historian, was the son of Robert Surtees of Mainsforth, Durham. He was educated at Christ Church, Oxford, and after studying law without being called to the bar he settled on the family estate at Mainsforth, which he inherited on his father's death in 1802, and where he lived in retirement for the rest of his life, devoting himself to the study of local antiquities and collecting materials for his *History of Durham*. This book was published in four volumes, the first of which appeared in 1816, and the last in 1840, after the author's death. The work contains a large amount of genealogical and antiquarian information; it is written in a readable style, and its learning is enlivened by humour. Surtees had also a gift for ballad writing, and he was so successful in imitating the style of old ballads that he managed to deceive Sir Walter Scott himself, who gave a place in his *Minstrelsy of the Scottish Border* to a piece by Surtees called "The Death of Featherstonehaugh," under the impression that it was ancient. Surtees, who in 1807 married Anne Robinson, died at Mainsforth on the 11th of February 1834. As a memorial of him the "Surtees Society" was founded in 1834 for the purpose of publishing ancient unedited manuscripts bearing on the history of the border country.

See G. Taylor, *Memoir of Robert Surtees*, with additions by J. Raine (Surtees Society, London, 1852).

SURTEES, ROBERT SMITH (1803–1864), English novelist and sporting writer, was the second son of Anthony Surtees of Hamsterley Hall, a member of an old Durham family. Educated to be a solicitor, Surtees soon began to contribute to the *Sporting Magazine*, and in 1831 he published a treatise on the law relating to horses and particularly the law of warranty, entitled *The Horseman's Manual*. In the following year he helped to found the *New Sporting Magazine*, of which he was the editor for the next five years. To this periodical he contributed between 1832 and 1834 the papers which were afterwards collected and published in 1838 as *Jorrocks's Jaunts and Jollities*. This humorous narrative of the sporting experiences of a cockney grocer, which suggested the more famous *Pickwick Papers* of Charles Dickens, is the work by which Surtees is chiefly remembered, though his novel *Handley Cross*, published in 1843, in which the character of "Jorrocks" is reintroduced as a master of fox-hounds, also enjoyed a wide popularity. The former of these two books was illustrated by "Phiz" (H. K. Browne), and the latter, as well as most of Surtees's subsequent novels, by John Leech, whose pictures of "Jorrocks" are everywhere familiar and were the chief means of ensuring the lasting popularity of that humorous creation. In 1838, on the death of his father, Surtees, whose elder brother had died in 1831, inherited the family property of Hamsterley Hall, where he lived for the rest of his life. The later novels by Surtees included *Hillingdon Hall* (1845), in which "Jorrocks" again appears; *Hawbuck Grange* (1847); *Mr Sponge's Sporting Tour* (1853); *Ask Mamma* (1858); *Plain or Ringlets?* (1860); *Mr Facey Romford's Hounds* (1865). The last of these novels appeared after the author's death, which occurred on the 16th of March 1864. In 1841 he married Elizabeth Jane, daughter of Addison Fenwick of Bishopwearmouth, by whom he had one son and two daughters, the younger of whom, Eleanor, in 1885 married John Prendergast Vereker, afterwards 5th Viscount Gort.

See R. S. Surtees, *Jorrocks's Jaunts and Jollities* (London, 1869), containing a biographical memoir of the author; W. P. Frith, *John Leech, His Life and Work* (2 vols., London, 1891); Samuel Halkett and J. Laing, *Dictionary of Anonymous and Pseudonymous Literature of Great Britain* (4 vols., Edinburgh, 1882–1888).

SURVEYING, the technical term for the art of determining the position of prominent points and other objects on the surface of the ground, for the purpose of making therefrom a graphic representation of the area surveyed. The general principles on which surveys are conducted and maps computed from such data are in all instances the same; certain measures are made on the ground, and corresponding measures are protracted on paper on whatever scale may be a convenient fraction of the natural scale. The method of surveying varies with the magnitude of the survey, which may embrace an empire or represent a small plot of land. All surveys rest primarily on linear measurements for the direct determination of distances; but linear measurement is often supplemented by angular measurement which enables distances to be determined by principles of geometry over areas which cannot be conveniently measured directly, such, for instance, as hilly or broken ground. The nature of the survey depends on the proportion which the linear and angular measures bear to one another and is almost always a combination of both.

History.—The art of surveying, *i.e.* the primary art of map-making from linear measurements, has no historical beginning. The first rude attempts at the representation of natural and artificial features on a ground plan based on actual measurements of which any record is obtainable were those of the Romans, who certainly made use of an instrument not unlike the plane-table for determining the alignment of their roads. Instruments adapted to surveying purposes were in use many centuries earlier than the Roman period. The Greeks used a form of log line for recording the distances run from point to point along the coast whilst making their slow voyage from the Indus to the Persian Gulf three centuries B.C.; and it is improbable that the adaptation of this form of linear measurement was confined to the sea alone. Still earlier (as early as 1600 B.C.) it is said that the Chinese knew the value of the loadstone and possessed some form of magnetic compass. But there is no record of their methods of linear measurements, or that the distances and angles measured were applied to the purpose of map-making (see COMPASS and MAP). The earliest maps of which we have any record were based on inaccurate astronomical determinations, and it was not till medieval times, when the Arabs made use of the Astrolabe (*q.v.*), that nautical surveying (the earliest form of the art) could really be said to begin. In 1450 the Arabs were acquainted with the use of the compass, and could make charts of the coast-line of those countries which they visited. In 1498 Vasco da Gama saw a chart of the coast-line of India, which was shown him by a Gujarati, and there can be little doubt that he benefited largely by information obtained from charts which were of the nature of practical coast surveys. The beginning of land surveying (apart from small plan-making) was probably coincident with the earliest attempts to discover the size and figure of the earth by means of exact measurements, *i.e.* with the inauguration of geodesy (see GEODESY and EARTH, FIGURE OF THE), which is the fundamental basis of all scientific surveying.

Classification.—For convenience of reference surveying may be considered under the following heads—involving very distinct branches of the art dependent on different methods and instruments[1]:—

1. Geodetic triangulation.
2. Levelling.
3. Topographical surveys.
4. Geographical surveys.
5. Traversing, and fiscal or revenue surveys.
6. Nautical surveys.

1. GEODETIC TRIANGULATION

Geodesy, as an abstract science dealing primarily with the dimensions and figure of the earth, may be found fully discussed in the articles GEODESY and EARTH, FIGURE OF THE; but, as furnishing the basis for the construction of the first framework of triangulation on which all further surveys depend (which may be described as its second but most important function), geodesy is an integral part of the art of surveying, and its relation to subsequent processes requires separate consideration. The part which geodetic triangulation plays in the general surveys of civilized countries which require closely accurate and various forms of mapping to illustrate their physical features for military, political or fiscal purposes is best exemplified by reference to some completed system which has already served its purpose over a large area. That of India will serve as an example.

The great triangulation of India was, at its inception, calculated to satisfy the requirements of geodesy as well as geography, because the latitudes and longitudes of the points of the triangulation had to be determined for future reference by process of calculation combining the results of the triangulation with the elements of the earth's figure. The latter were not then known with much accuracy, for so far geodetic operations had been mainly carried on in Europe, and additional operations nearer the equator were much wanted; the survey was conducted with a view to supply this want. Thus high accuracy was aimed at from the first.

Primarily a network was thrown over the southern peninsula. The triangles on the central meridian were measured with extra care and checked by base-lines at distances of about 2° apart in

[1] The subject of tacheometry is treated under its own heading.

latitude in order to form a geodetic arc, with the addition of astronomically determined latitudes at certain of the stations. The base-lines were measured with chains and the principal angles with a 3-ft. theodolite. The signals were cairns of stones or poles. The chains were somewhat rude and their units of length had not been determined originally, and could not be afterwards ascertained. The results were good of their kind and sufficient for geographical purposes; but the central meridional arc—the "great arc"—was eventually deemed inadequate for geodetic requirements. A superior instrumental equipment was introduced, with an improved

Trigonometrical Survey of India.

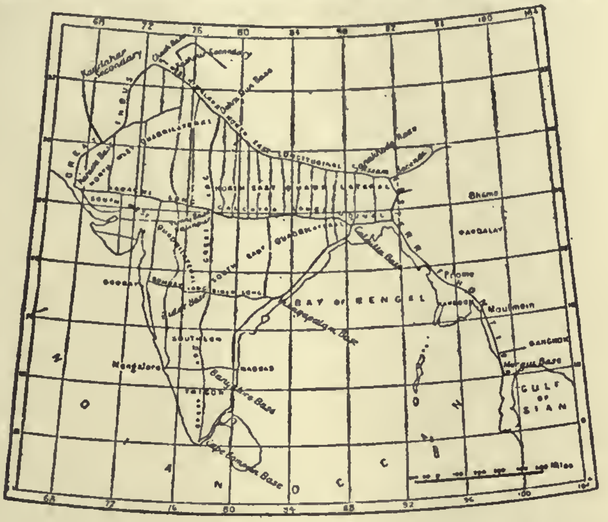

FIG. 1.

modus operandi, under the direction of Colonel Sir G. Everest in 1832. The network system of triangulation was superseded by meridional and longitudinal chains taking the form of gridirons and resting on base-lines at the angles of the gridirons, as represented in fig. 1. For convenience of reduction and nomenclature the triangulation west of meridian 92° E. has been divided into five sections—the lowest a trigon, the other four quadrilaterals distinguished by cardinal points which have reference to an observatory in Central India, the adopted origin of latitudes. In the north-east quadrilateral, which was first measured, the meridional chains are about one degree apart; this distance was latterly much increased and eventually certain chains—as on the Malabar coast and on meridian 84° in the south-east quadrilateral—were dispensed with because good secondary triangulation for topography had been accomplished before they could be begun.

All *base-lines* were measured with the Colby apparatus of compensation bars and microscopes. The bars, 10 ft. long, were set up horizontally on tripod stands; the microscopes, 6 in. apart, were mounted in pairs revolving round a vertical axis and were set up on tribrachs fitted to the ends of the bars. Six bars and five central and two end pairs of microscopes—the latter with their vertical axes perforated for a look-down telescope—constituted a complete apparatus, measuring 63 ft. between the ground pins or registers. Compound bars are more liable to accidental changes of length than simple bars; they were therefore tested from time to time by comparison with a standard simple bar; the microscopes were also tested by comparison with a standard 6-in. scale. At the first base-line the compensated bars were found to be liable to sensible variations of length with the diurnal variations of temperature; these were supposed to be due to the different thermal conductivities of the brass and the iron components. It became necessary, therefore, to determine the mean daily length of the bars precisely, for which reason they were systematically compared with the standard before and after, and sometimes at the middle of, the base-line measurement throughout the entire day for a space of three days, and under conditions as nearly similar as possible to those obtaining during the measurement. Eventually thermometers were applied experimentally to both components of a compound bar, when it was found that the diurnal variations in length were principally due to difference of position relatively to the sun, not to difference of conductivity—the component nearest the sun acquiring heat most rapidly or parting with it most slowly, notwithstanding that both were in the same box, which was always sheltered from the sun's rays. Happily the systematic comparisons of the compound bars with the standard were found to give a sufficiently exact determination of the mean daily length. An elaborate investigation of theoretical probable errors (*p.e.*) at the Cape Comorin base showed that, for any base-line measured as usual without thermometers in the compound bars, the *p.e.* may be taken as $\pm 1 \cdot 5$ millionth parts of the length, excluding unascertainable constant errors, and that on introducing thermometers into these bars the *p.e.* was diminished to $\pm 0 \cdot 55$ millionths.

In all base-line measurements the weak point is the determination of the temperature of the bars when that of the atmosphere is rapidly rising or falling; the thermometers acquire and lose heat more rapidly than the bar if their bulbs are outside, and more slowly if inside the bar. Thus there is always more or less lagging, and its effects are only eliminated when the rises and falls are of equal amount and duration; but as a rule the rise generally predominates greatly during the usual hours of work, and whenever this happens lagging may cause more error in a base-line measured with simple bars than all other sources of error combined. In India the probable average lagging of the standard-bar thermometer was estimated as not less than 0·3° F., corresponding to an error of − 2 millionths in the length of a base-line measured with iron bars. With compound bars lagging would be much the same for both components and its influence would consequently be eliminated. Thus the most perfect base-line apparatus would seem to be one of compensation bars with thermometers attached to each component; then the comparisons with the standard need only be taken at the times when the temperature is constant, and there is no lagging.

The *plan of triangulation* was broadly a system of internal meridional and longitudinal chains with an external border of oblique chains following the course of the frontier and the coast lines. The design of each chain was necessarily much influenced by the physical features of the country over which it was carried. The most difficult tracts were plains, devoid of any commanding points of view, in some parts covered with forest and jungle, malarious and almost uninhabited, in other parts covered with towns and villages and umbrageous trees. In such tracts triangulation was impossible except by constructing towers as stations of observation, raising them to a sufficient height to overtop at least the earth's curvature, and then either increasing the height to surmount all obstacles to mutual vision, or clearing the lines. Thus in hilly and open country the chains of triangles were generally made "double" throughout, *i.e.* formed of polygonal and quadrilateral figures to give greater breadth and accuracy; but in forest and close country they were carried out as series of single triangles, to give a minimum of labour and expense. Symmetry was secured by restricting the angles between the limits of 30° and 90°. The average side length was 30 m. in hill country and 11 in the plains; the longest principal side was 62·7 m., though in the secondary triangulation to the Himalayan peaks there were sides exceeding 200 m. Long sides were at first considered desirable, on the principle that the fewer the links the greater the accuracy of a chain of triangles; but it was eventually found that good observations on long sides could only be obtained under exceptionally favourable atmospheric conditions. In plains the length was governed by the height to which towers could be conveniently raised to surmount the curvature, under the well-known condition, height in feet = $\frac{2}{3} \times$ square of the distance in miles; thus 24 ft. of height was needed at each end of a side to overtop the curvature in 12 m., and to this had to be added whatever was required to surmount obstacles on the ground. In Indian plains refraction is more frequently negative than positive during sunshine; no reduction could therefore be made for it.

The *selection of sites for stations*, a simple matter in hills and open country, is often difficult in plains and close country. In the early operations, when the great arc was being carried across the wide plains of the Gangetic valley, which are covered with villages and trees and other obstacles to distant vision, masts 35 ft. high were carried about for the support of the small reconnoitring theodolites, with a sufficiency of poles and bamboos to form a scaffolding of the same height for the observer. Other masts 70 ft. high, with arrangements for displaying blue lights by night at 90 ft., were erected at the spots where station sites were wanted. But the cost of transport was great, the rate of progress was slow, and the results were unsatisfactory. Eventually a method of touch rather than sight was adopted, feeling the ground to search for the obstacles to be avoided, rather than attempting to look over them: the "rays" were traced either by a minor triangulation, or by a traverse with theodolite and perambulator, or by a simple alignment of flags. The first method gives the direction of the new station most accurately; the second searches the ground most closely; the third is best suited for tracts of uninhabited forest in which there is no choice of either line or site, and the required station may be built at the intersection of the two trial rays leading up to it. As a rule it has been found most economical and expeditious to raise the towers only to the height necessary for surmounting the curvature, and to remove the trees and other obstacles on the lines.

Each *principal station* has a central masonry pillar, circular and 3 to 4 ft. in diameter, for the support of a large theodolite, and around it a platform 14 to 16 ft. square for the observatory tent, observer and signallers. The pillar is isolated from the platform, and when solid carries the station mark—a dot surrounded by a circle—engraved on a stone at its surface, and on additional stones or the rock *in situ*, in the normal of the upper mark; but, if the height is considerable and there is a liability to deflection, the pillar is constructed with a central vertical shaft to enable the theodolite to be plumbed over the ground-level mark, to which access is obtained through a passage in the basement. In early years this precaution against deflection was neglected and the pillars were built solid throughout, whatever their height; the surrounding platforms, being usually constructed of sun-dried bricks or stones and earth, were liable to fall and press against the pillars, some of which thus became deflected during the rainy seasons that intervened between the periods during which operations were arrested or the beginning and close of the successive circuits of triangles. Large theodolites were invariably employed. Repeating circles were highly thought of by French geodesists at the time when the operations in India were begun; but they were not used in the survey, and have now been generally discarded. The principal theodolites were somewhat similar to the astronomer's alt-azimuth instrument, but with larger azimuthal and smaller vertical circles, also with a greater base to give the firmness and stability which are required in measuring horizontal angles. The azimuthal circles had mostly diameters of either 36 or 24 in., the vertical circles having a diameter of 18 in. In all the theodolites the base was a tribrach resting on three levelling foot-screws, and the circles are read by microscopes; but in different instruments the fixed and the rotatory parts of the body varied. In some the vertical axis was fixed on the tribrach and projected upwards; in others it revolved in the tribrach and projected downwards. In the former the azimuthal circle was fixed to the tribrach, while the telescope pillars, the microscopes, the clamps and the tangent screws were attached to a drum revolving round the vertical axis; in the latter the microscopes, clamps and tangent screws were fixed to the tribrach, while the telescope pillars and the azimuthal circle were attached to a plate fixed at the head of the rotary vertical axis.

Cairns of stones, poles or other opaque signals were primarily employed, the angles being measured by day only; eventually it was found that the atmosphere was often more favourable for observing by night than by day, and that distant points were raised well into view by refraction by night which might be invisible or only seen with difficulty by day. Lamps were then introduced of the simple form of a cup, 6 in. in diameter, filled with cotton seeds steeped in oil and resin, to burn under an inverted earthen jar, 30 in. in diameter, with an aperture in the side towards the observer. Subsequently this contrivance gave place to the Argand lamp with parabolic reflector; the opague day signals were discarded for heliotropes reflecting the sun's rays to the observer. The introduction of luminous signals not only rendered the night as well as the day available for the observations but changed the character of the operations, enabling work to be done during the dry and healthy season of the year, when the atmosphere is generally hazy and dust-laden, instead of being restricted as formerly to the rainy and unhealthy seasons, when distant opaque objects are best seen. A higher degree of accuracy was also secured, for the luminous signals were invariably displayed through diaphragms of appropriate aperture, truly centred over the station mark; and, looking like stars, they could be observed with greater precision, whereas opaque signals are always dim in comparison and are liable to be seen excentrically when the light falls on one side. A signalling party of three men was usually found sufficient to manipulate a pair of heliotropes—one for single, two for double reflection, according to the sun's position—and a lamp, throughout the night and day. Heliotropers were also employed at the observing stations to flash instructions to the signallers.

Measuring Horizontal Angles.

The theodolites were invariably set up under tents for protection against sun, wind and rain, and centred, levelled and adjusted for the runs of the microscopes. Then the signals were observed in regular rotation round the horizon, alternately from right to left and vice versa; after the prescribed minimum number of rounds, either two or three, had been thus measured, the telescope was turned through 180°, both in altitude and azimuth, changing the position of the face of the vertical circle relatively to the observer, and further rounds were measured; additional measures of single angles were taken if the prescribed observations were not sufficiently accordant. As the microscopes were invariably equidistant and their number was always odd, either three or five, the readings taken on the azimuthal circle during the telescope pointings to any object in the two positions of the vertical circle, "face right" and "face left," were made on twice as many equidistant graduations as the number of microscopes. The theodolite was then shifted bodily in azimuth, by being turned on the ring on the head of the stand, which brought new graduations under the microscopes at the telescope pointings; then further rounds were measured in the new positions, face right and face left. This process was repeated as often as had been previously prescribed, the successive angular shifts of position being made by equal arcs bringing equidistant graduations under the microscopes during the successive telescope pointings to one and the same object. By these arrangements all periodic errors of graduation were eliminated, the numerous graduations that were read tended to cancel accidental errors of division, and the numerous rounds of measures to minimize the errors of observation arising from atmospheric and personal causes.

Under this system of procedure the instrumental and ordinary errors are practically cancelled and any remaining error is most probably due to lateral refraction, more especially when the rays of light graze the surface of the ground. The three angles of every triangle were always measured.

Vertical Angles.

The apparent altitude of a distant point is liable to considerable variations during the twenty-four hours, under the influence of changes in the density of the lower strata of the atmosphere. Terrestrial refraction is capricious, more particularly when the rays of light graze the surface of the ground, passing through a medium which is liable to extremes of rarefaction and condensation, under the alternate influence of the sun's heat radiated from the surface of the ground and of chilled atmospheric vapour. When the back and forward verticals at a pair of stations are equally refracted, their difference gives an exact measure of the difference of height. But the atmospheric conditions are not always identical at the same moment everywhere on long rays which graze the surface of the ground, and the ray between two reciprocating stations is liable to be differently refracted at its extremities, each end being influenced in a greater degree by the conditions prevailing around it than by those at a distance; thus instances are on record of a station A being invisible from another B, while B was visible from A.

Refraction.

When the great arc entered the plains of the Gangetic valley, simultaneous reciprocal verticals were at first adopted with the hope of eliminating refraction; but it was soon found that they did not do so sufficiently to justify the expense of the additional instruments and observers. Afterwards the back and forward verticals were observed as the stations were visited in succession, the back angles at as nearly as possible the same time of the day as the forward angles, and always during the so-called "time of minimum refraction," which ordinarily begins about an hour after apparent noon and lasts from two to three hours. The apparent zenith distance is always greatest then, but the refraction is a minimum only at stations which are well elevated above the surface of the ground; at stations on plains the refraction is liable to pass through zero and attain a considerable negative magnitude during the heat of the day, for the lower strata of the atmosphere are then less dense than the strata immediately above and the rays are refracted downwards. On plains the greatest positive refractions are also obtained—maximum values, both positive and negative, usually occurring, the former by night, the latter by day, when the sky is most free from clouds. The values actually met with were found to range from + 1·21 down to −0·09 parts of the contained arc on plains; the normal "coefficient of refraction" for free rays between hill stations below 6000 ft. was about 0·07, which diminished to 0·04 above 18,000 ft., broadly varying inversely as the temperature and directly as the pressure, but much influenced also by local climatic conditions.

In measuring the vertical angles with the great theodolites, graduation errors were regarded as insignificant compared with errors arising from uncertain refraction; thus no arrangement was made for effecting changes of zero in the circle settings. The observations were always taken in pairs, face right and left, to eliminate index errors, only a few daily, but some on as many days as possible, for the variations from day to day were found to be greater than the diurnal variations during the hours of minimum refraction.

Weights.

In the ordnance and other surveys the bearings of the surrounding stations are deduced from the actual observations, but from the "included angles" in the Indian survey. The observations of every angle are tabulated vertically in as many columns as the number of circle settings face left and face right, and the mean for each setting is taken. For several years the general mean of these was adopted as the final result; but subsequently a "concluded angle" was obtained by combining the single means with weights inversely proportional to $g^2 + o^2 \div n$—g, being a value of the *e.m.s.*[1] of graduation derived empirically from the differences between the general mean and the mean for each setting, o the *e.m.s.* of observation deduced from the differences between the individual measures and their respective means, and n the number of measures at each setting. Thus, putting $w_1, w_2, \dots$ for the weights of the single means, w for the weight of the concluded angle, M for the general mean, C for the concluded angle, and $d_1, d_2, \dots$ for the differences between M and the single means, we have

$$C = M + \frac{w_1 d_1 + w_2 d_2 +}{w_1 + w_2 +} \tag{1}$$

and

$$w = w_1 + w_2 + \tag{2}$$

$C - M$ vanishes when n is constant; it is inappreciable when g is much larger than o; it is significant only when the graduation errors are more minute than the errors of observation; but it was always small, not exceeding 0·14″ with the system of two rounds of measures and 0·05″ with the system of three rounds.

The weights of the concluded angles thus obtained were employed in the primary reductions of the angles of single triangles and polygons which were made to satisfy the geometrical conditions

[1] The theoretical "error of mean square" = 1·48 × "probable error."

of each figure, because they were strictly relative for all angles measured with the same instrument and under similar circumstances and conditions, as was almost always the case for each single figure. But in the final reductions, when numerous chains of triangles composed of figures executed with different instruments and under different circumstances came to be adjusted simultaneously, it was necessary to modify the original weights, on such evidence of the precision of the angles as might be obtained from other and more reliable sources than the actual measures of the angles. This treatment will now be described.

Theoretical Errors of Angles.

Values of theoretical error for groups of angles measured with the same instrument and under similar conditions may be obtained in three ways—(i.) from the squares of the reciprocals of the weight w deduced as above from the measures of such angle, (ii.) from the magnitudes of the excess of the sum of the angles of each triangle above 180°+ the spherical excess, and (iii.) from the magnitudes of the corrections which it is necessary to apply to the angles of polygonal figures and networks to satisfy the several geometrical conditions.

Harmonizing Angles.

Every figure, whether a single triangle or a polygonal network, was made consistent by the application of corrections to the observed angles to satisfy its geometrical conditions. The three angles of every triangle having been observed, their sum had to be made = 180° + the spherical excess; in networks it was also necessary that the sum of the angles measured round the horizon at any station should be exactly = 360°, that the sum of the parts of an angle measured at different times should equal the whole and that the ratio of any two sides should be identical, whatever the route through which it was computed. These are called the *triangular, central, toto-partial* and *side* conditions; they present n geometrical equations, which contain t unknown quantities, the errors of the observed angles, t being always $>n$. When these equations are satisfied and the deduced values of errors are applied as corrections to the observed angles, the figure becomes consistent. Primarily the equations were treated by a method of successive approximations; but afterwards they were all solved simultaneously by the so-called method of minimum squares, which leads to the most probable of any system of corrections.

Sides of Triangles.

The angles having been made geometrically consistent *inter se* in each figure, the side-lengths are computed from the base-line onwards by Legendre's theorem, each angle being diminished by one-third of the spherical excess of the triangle to which it appertains. The theorem is applicable without sensible error to triangles of a much larger size than any that are ever measured.

Latitude and Longitude of Stations; Azimuth of Sides.

A station of origin being chosen of which the latitude and longitude are known astronomically, and also the azimuth of one of the surrounding stations, the differences of latitude and longitude and the reverse azimuths are calculated in succession, for all the stations of the triangulation, by Puissant's formulae (*Traité de géodésie*, 3rd ed., Paris, 1842).

Problem.—Assuming the earth to be spheroidal, let A and B be two stations on its surface, and let the latitude and longitude of A be known, also the azimuth of B at A, and the distance between A and B at the mean sea-level; we have to find the latitude and longitude of B and the azimuth of A at B.

The following symbols are employed: a the major and b the minor semi-axis; e the excentricity, $=\left\{\frac{a^2-b^2}{a^2}\right\}^{\frac{1}{2}}$; ρ the radius of curvature to the meridian in latitude λ, $=\frac{a(1-e^2)}{\{1-e^2\sin^2\lambda\}^{\frac{3}{2}}}$; ν the normal to the meridian in latitude λ, $=\frac{a}{\{1-e^2\sin^2\lambda\}^{\frac{1}{2}}}$; λ and L the given latitude and longitude of A; $\lambda+\Delta\lambda$ and $L+\Delta L$ the required latitude and longitude of B; A the azimuth of B at A; B the azimuth of A at B; $\Delta A=B-(\pi+A)$; c the distance between A and B. Then, all azimuths being measured from the south, we have

$$\Delta\lambda''=\left\{\begin{aligned}&-\frac{c}{\rho}\cos A\ \text{cosec}\ 1''\\&-\frac{1}{2}\frac{c^2}{\rho.\nu}\sin^2 A\tan\lambda\ \text{cosec}\ 1''\\&-\frac{3}{4}\frac{c^2}{\rho.\nu}\frac{e^2}{1-e^2}\cos^2 A\sin 2\lambda\ \text{cosec}\ 1''\\&+\frac{1}{6}\frac{c^3}{\rho.\nu^2}\sin^2 A\cos A(1+3\tan^2\lambda)\ \text{cosec}\ 1''\end{aligned}\right\}\quad(3)$$

$$\Delta L''=\left\{\begin{aligned}&-\frac{c}{\nu}\frac{\sin A}{\cos\lambda}\text{cosec}\ 1''\\&+\frac{1}{2}\frac{c^2}{\nu^2}\frac{\sin 2A\tan\lambda}{\cos\lambda}\text{cosec}\ 1''\\&-\frac{1}{6}\frac{c^3}{\nu^3}\frac{(1+3\tan^2\lambda)\sin 2A\cos A}{\cos\lambda}\text{cosec}\ 1''\\&+\frac{1}{3}\frac{c^3}{\nu^3}\frac{\sin^3 A\tan^2\lambda}{\cos\lambda}\text{cosec}\ 1''\end{aligned}\right\}\quad(4)$$

$$\begin{aligned}&\Delta A''\ \text{or}\\&B-(\pi+A)\end{aligned}=\left\{\begin{aligned}&-\frac{c}{\nu}\sin A\tan\lambda\ \text{cosec}\ 1''\\&+\frac{1}{4}\frac{c^2}{\nu^2}\left\{1+2\tan^2\lambda+\frac{e^2\cos^2\lambda}{1-e^2}\right\}\sin 2A\ \text{cosec}\ 1''\\&-\frac{c^3}{\nu^3}\left(\frac{5}{6}+\tan^2\lambda\right)\frac{\tan\lambda}{2}\sin 2A\cos A\ \text{cosec}\ 1''\\&+\frac{1}{6}\frac{c^3}{\nu^3}\sin^3 A\tan\lambda(1+2\tan^2\lambda)\ \text{cosec}\ 1''\end{aligned}\right\}\quad(5)$$

Each Δ is the sum of four terms symbolized by δ_1, δ_2, δ_3 and δ_4; the calculations are so arranged as to produce these terms in the order $\delta\lambda$, δL, and δA, each term entering as a factor in calculating the following term. The arrangement is shown below in equations in which the symbols $P, Q, \ldots Z$ represent the factors which depend on the adopted geodetic constants, and vary with the latitude; the logarithms of their numerical values are tabulated in the *Auxiliary Tables to Facilitate the Calculations of the Indian Survey.*

$$\left.\begin{aligned}&\delta_1\lambda=-P.\cos A.c && \delta_1 L=+\delta_1\lambda.Q.\sec\lambda.\tan A && \delta_1 A=+\delta_1 L.\sin\lambda\\&\delta_2\lambda=+\delta_1 A.R.\sin A.c && \delta_2 L=-\delta_2\lambda.S.\cot A && \delta_2 A=+\delta_2 L.T\\&\delta_3\lambda=-\delta_2 A.V.\cot A && \delta_3 L=+\delta_3\lambda.U.\sin A.c && \delta_3 A=+\delta_3 L.W\\&\delta_4\lambda=-\delta_3 A.X.\tan A && \delta_4 L=+\delta_4\lambda.Y.\tan A && \delta_4 A=+\delta_4 L.Z\end{aligned}\right\}\quad(6)$$

Reduction of Principal Triangulation.

The calculations described so far suffice to make the angles of the several trigonometrical figures consistent *inter se*, and to give preliminary values of the lengths and azimuths of the sides and the latitudes and longitudes of the stations. The results are amply sufficient for the requirements of the topographer and land surveyor, and they are published in preliminary charts, which give full numerical details of latitude, longitude, azimuth and side-length, and of height also, for each portion of the triangulation—secondary as well as principal—as executed year by year. But on the completion of the several chains of triangles further reductions became necessary, to make the triangulation everywhere consistent *inter se* and with the verificatory base-lines, so that the lengths and azimuths of common sides and the latitudes and longitudes of common stations should be identical at the junctions of chains and that the measured and computed lengths of the base-lines should also be identical.

As an illustration of the problem for treatment, suppose a combination of three meridional and two longitudinal chains comprising seventy-two single triangles with a base-line at each corner as shown in the accompanying diagram (fig. 2); suppose the three angles of every triangle to have been measured and made consistent. Let A be the origin, with its latitude and longitude given, and also the length and azimuth of the adjoining base-line. With these data processes of calculation are carried through the triangulation to obtain the lengths and azimuths of the sides and the latitudes and longitudes of the stations, say in the following order: from A through B to E, through F to E, through F to D, through F and E to C, and through F and D to C. Then there are two values of side, azimuth, latitude and longitude at E—one from the right-hand chains via B, the other from the left-hand chains via F; similarly there are two sets of values at C; and each of the base-lines at B, C and D has a calculated as well as a measured value. Thus eleven absolute errors are presented for dispersion over the triangulation by the application of the most appropriate correction to each angle, and, as a preliminary to the determination of these corrections, equations must be constructed between each of the absolute errors and the unknown errors of the angles from which they originated. For this purpose assume X to be the angle opposite the flank side of any triangle, and Y and Z the angles opposite the sides of continuation; also let x, y and z be the most probable values of the errors of the angles which will satisfy the given equations of condition. Then each equation may be expressed in the form $[ax+by+cz]=E$, the brackets indicating a summation for all the triangles involved. We have first to ascertain the values of the coefficients a, b and c of the unknown quantities. They are readily found for the side equations on the circuits and between the base-lines, for x does not enter them, but only y and z, with coefficients which are the cotangents of Y and Z, so that these equations are simply $[\cot Y.y-\cot Z.z]=E$. But three out of four of the circuit equations are geodetic, corresponding to the closing errors in latitude, longitude and azimuth, and in them the coefficients are very complicated. They are obtained as follows. The first term of each of the three expressions for $\Delta\lambda$, ΔL, and B is differentiated in terms of c and A, giving

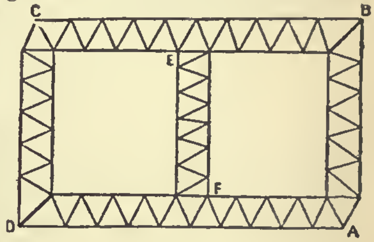

FIG. 2.

$$\left.\begin{aligned}d.\Delta\lambda&=\Delta\lambda\left\{\frac{dc}{c}-dA\tan A\sin 1''\right\}\\d.\Delta L&=\Delta L\left\{\frac{dc}{c}+dA\cot A\sin 1''\right\}\\dB=dA+\Delta A&\left\{\frac{dc}{c}+dA\cot A\sin 1''\right\}\end{aligned}\right\}\quad(7)$$

in which dc and dA represent the errors in the length and azimuth of any side c which have been generated in the course of the triangulation up to it from the base-line and the azimuth station at the origin. The errors in the latitude and longitude of any station which are due to the triangulation are $d\lambda$, $=[d.\Delta\lambda]$, and dL, $=[d.\Delta L]$. Let station 1 be the origin, and let 2, 3, ... be the succeeding stations taken along a predetermined line of traverse, which may either run from vertex to vertex of the successive triangles, zigzagging between the flanks of the chain, as in fig. 3 (1), or be carried directly along one of the flanks, as in fig. 3 (2). For the general symbols of the differential equations substitute $\Delta\lambda_n$, ΔL_n, ΔA_n, c_n, A_n, and B_n, for the side between stations n and $n+1$ of the traverse; and let δc_n and δA_n be the errors generated between the sides c_{n-1} and c_n; then

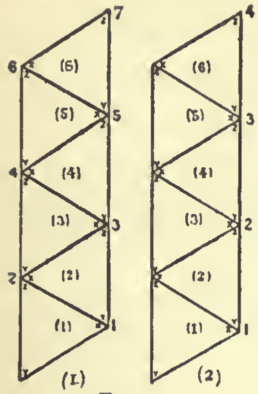

FIG. 3.

$$\frac{dc_1}{c_1}=\frac{\delta c_1}{c_1};\quad \frac{dc_2}{c_2}=\frac{\delta c_1}{c_1}+\frac{\delta c_2}{c_2};\dots\quad \frac{dc_n}{c_n}=\sideset{_1^n}{}{\left[\frac{\delta c}{c}\right]};$$
$$dA_1=\delta A_1;\ dA_2=dB_1+\delta A_2;\ \dots\ dA_n=dB_{n-1}+\delta A_n.$$

Performing the necessary substitutions and summations, we get

$$dB_n=\begin{cases}{}_1^n[\Delta A]\frac{\delta c_1}{c_1}+{}_2^n[\Delta A]\frac{\delta c_2}{c_2}+\dots+\Delta A_n\frac{\delta c_n}{c_n}\\ +(1+{}_1^n[\Delta A\cot A]\sin 1'')\delta A_1+(1+{}_2^n[\Delta A\cot A]\sin 1'')\delta A_2\\ \quad+\dots+(1+\Delta A_n\cot A_n\sin 1'')\delta A_n.\end{cases}$$

$$d\lambda_{n+1}=\begin{cases}{}_1^n[\Delta\lambda]\frac{\delta c_1}{c_1}+{}_2^n[\Delta\lambda]\frac{\delta c_2}{c_2}+\dots+\Delta\lambda_n\frac{\delta c_n}{c_n}\\ -\{{}_1^n[\Delta\lambda\tan A]\delta A_1+{}_2^n[\Delta\lambda\tan A]\delta A_2+\dots\\ \quad+\Delta\lambda_n\tan A_n\delta A_n\}\sin 1''\end{cases}$$

$$dL_{n+1}=\begin{cases}{}_1^n[\Delta L]\frac{\delta c_1}{c_1}+{}_2^n[\Delta L]\frac{\delta c_2}{c_2}+\dots+\Delta L_n\frac{\delta c_n}{c_n}\\ +\{{}_1^n[\Delta L\cot A]\delta A_1+{}_2^n[\Delta L\cot A]\delta A_2+\dots\\ \quad+\Delta L_n\cot A_n\delta A_n\}\sin 1''.\end{cases}$$

Thus we have the following expression for any geodetic error:—

$$\mu_1\frac{\delta c_1}{c_1}+\dots+\mu_n\frac{\delta c_n}{c_n}+\phi_1\delta A_1+\dots+\phi_n\delta A_n=E, \qquad (8)$$

where μ and ϕ represent the respective summations which are the coefficients of δc and δA in each instance but the first, in which 1 is added to the summation in forming the coefficient of δA.

The angular errors x, y and z must now be introduced, in place of δc and δA, into the general expression, which will then take different forms, according as the route adopted for the line of traverse was the zigzag or the direct. In the former, the number of stations on the traverse is ordinarily the same as the number of triangles, and, whether or no, a common numerical notation may be adopted for both the traverse stations and the collateral triangles; thus the angular errors of every triangle enter the general expression in the form $\qquad \pm\phi x+\cot Y.\mu' y-\cot Z.\mu' z,$

in which $\mu'=\mu\sin 1''$, and the upper sign of ϕ is taken if the triangle lies to the left, the lower if to the right, of the line of traverse. When the direct traverse is adopted, there are only half as many traverse stations as triangles, and therefore only half the number of μ's and ϕ's to determine; but it becomes necessary to adopt different numberings for the stations and the triangles, and the form of the coefficients of the angular errors alternates in successive triangles. Thus, if the pth triangle has no side on the line of the traverse but only an angle at the lth station, the form is

$$+\phi_l.x_p+\cot Y_p.\mu_l'.y_p-\cot Z_p.\mu_l'.z_p.$$

If the qth triangle has a side between the lth and the $(l+1)$th stations of the traverse, the form is

$$\cot X_q(\mu_l'-\mu'_{l+1})x_q+(\phi_l+\mu'_{l+1}\cot Y_q)y_q-(\phi_{l+1}-\mu_l'\cot Z_q)z_q.$$

As each circuit has a right-hand and a left-hand branch, the errors of the angles are finally arranged so as to present equations of the general form

$$[ax+by+cz]_r-[ax+by+cz]_l=E.$$

The eleven circuit and base-line equations of condition having been duly constructed, the next step is to find values of the angular errors which will satisfy these equations, and be the most probable of any system of values that will do so, and at the same time will not disturb the existing harmony of the angles in each of the seventy-two triangles. Harmony is maintained by introducing the equation of condition $x+y+z=0$ for every triangle. The most probable results are obtained by the method of minimum squares, which may be applied in two ways.

i. A factor λ may be obtained for each of the eighty-three equations under the condition that $\left[\frac{x^2}{u}+\frac{y^2}{v}+\frac{z^2}{w}\right]$ is made a minimum, u, v and w being the *reciprocals* of the weights of the observed angles. This necessitates the simultaneous solution of eighty-three equations to obtain as many values of λ. The resulting values of the errors of the angles in any, the pth, triangle, are

$$x_p=u_p[a_p\lambda];\ y_p=v_p[b_p\lambda];\ z_p=w_p[c_p\lambda]. \qquad (9)$$

ii. One of the unknown quantities in every triangle, as x, may be eliminated from each of the eleven circuit and base-line equations by substituting its equivalent $-(y+z)$ for it, a similar substitution being made in the minimum. Then the equations take the form $[(b-a)y+(c-a)z]=E$, while the minimum becomes

$$\left[\frac{(y+z)^2}{u}+\frac{y^2}{v}+\frac{z^2}{w}\right].$$

Thus we have now to find only eleven values of λ by a simultaneous solution of as many equations, instead of eighty-three values from eighty-three equations; but we arrive at more complex expressions for the angular errors as follows:—

$$\left.\begin{aligned}y_p&=\frac{v_p}{u_p+v_p+w_p}\{(u_p+w_p)[(b_p-a_p)\lambda]-w_p[(c_p-a_p)\lambda]\}\\ z_p&=\frac{w_p}{u_p+v_p+w_p}\{(u_p+v_p)[(c_p-a_p)\lambda]-v_p[(b_p-a_p)\lambda]\}\end{aligned}\right\}. \qquad (10)$$

The second method has invariably been adopted, originally because it was supposed that, the number of the factors λ being reduced from the total number of equations to that of the circuit and base-line equations, a great saving of labour would be effected. But subsequently it was ascertained that in this respect there is little to choose between the two methods; for, when x is not eliminated, and as many factors are introduced as there are equations, the factors for the triangular equations may be readily eliminated at the outset. Then the really severe calculations will be restricted to the solution of the equations containing the factors for the circuit and base-line equations as in the second method.

In the preceding illustration it is assumed that the base-lines are errorless as compared with the triangulation. Strictly speaking, however, as base-lines are fallible quantities, presumably of different weight, their errors should be introduced as unknown quantities of which the most probable values are to be determined in a simultaneous investigation of the errors of all the facts of observation, whether linear or angular. When they are connected together by so few triangles that their ratios may be deduced as accurately, or nearly so, from the triangulation as from the measured lengths, this ought to be done; but, when the connecting triangles are so numerous that the direct ratios are of much greater weight than the trigonometrical, the errors of the base-lines may be neglected. In the reduction of the Indian triangulation it was decided, after examining the relative magnitudes of the probable errors of the linear and the angular measures and ratios, to assume the base-lines to be errorless.

The chains of triangles being largely composed of polygons or other networks, and not merely of single triangles, as has been assumed for simplicity in the illustration, the geometrical harmony to be maintained involved the introduction of a large number of "side," "central" and "toto-partial" equations of condition, as well as the triangular. Thus the problem for attack was the simultaneous solution of a number of equations of condition = that of all the geometrical conditions of every figure + four times the number of circuits formed by the chains of triangles + the number of base-lines − 1, the number of unknown quantities contained in the equations being that of the whole of the observed angles; the method of procedure, if rigorous, would be precisely similar to that already indicated for "harmonizing the angles of trigonometrical figures," of which it is merely an expansion from single figures to great groups.

The rigorous treatment would, however, have involved the simultaneous solution of about 4000 equations between 9230 unknown quantities, which was impracticable. The triangulation was therefore divided into sections for separate reduction, of which the most important were the five between the meridians of 67° and 92° (see fig. 1), consisting of four quadrilateral figures and a trigon, each comprising several chains of triangles and some base-lines. This arrangement had the advantage of enabling the final reductions to be taken in hand as soon as convenient after the completion of any section, instead of being postponed until all were completed. It was subject, however, to the condition that the sections containing the best chains of triangles were to be first reduced; for, as all chains bordering contiguous sections would necessarily be "fixed" as a part of the section first reduced, it was obviously desirable to run no risk of impairing the best chains by forcing them into adjustment with others of inferior quality. It happened that both the north-east and the south-west quadrilaterals contained several of the older chains; their reduction was therefore made to follow that of the collateral sections containing the modern chains.

But the reduction of each of these great sections was in itself a very formidable undertaking, necessitating some departure from a purely rigorous treatment. For the chains were largely composed of polygonal networks and not of single triangles only as assumed in the illustration, and therefore cognizance had to be taken of a number of "side" and other geometrical equations of condition, which entered irregularly and caused great entanglement. Equations 9 and 10 of the illustration are of a simple form because they have a single geometrical condition to maintain, the triangular, which is not only expressed by the simple and symmetrical equation $x+y+z=0$, but—what is of much greater importance—recurs in a regular order of sequence that materially facilitates the general solution. Thus, though the calculations must in all cases be very numerous and laborious, rules can be formulated under which they can be well controlled at every stage and eventually brought to a successful issue. The other geometrical conditions of networks are expressed by equations which are not merely of a more complex form but have no regular order of sequence, for the networks present a variety of forms; thus their introduction would cause much entanglement and complication, and greatly increase the labour of the calculations and the chances of failure. Wherever, therefore, any compound figure occurred, only so much of it as was required to form a chain of single triangles was employed. The figure having previously been made consistent, it was immaterial what part was employed, but the selection was usually made so as to introduce the fewest triangles. The triangulation for final simultaneous reduction was thus made to consist of chains of single triangles only; but all the included angles were "fixed" simultaneously. The excluded angles of compound figures were subsequently harmonized with the fixed angles, which was readily done for each figure *per se*.

This departure from rigorous accuracy was not of material importance, for the angles of the compound figures excluded from the simultaneous reduction had already, in the course of the several independent figural adjustments, been made to exert their full influence on the included angles. The figural adjustments had, however, introduced new relations between the angles of different figures, causing their weights to increase *caeteris paribus* with the number of geometrical conditions satisfied in each instance. Thus, suppose w to be the average weight of the t observed angles of any figure, and n the number of geometrical conditions presented for satisfaction; then the average weight of the angles after adjustment may be taken as $w.\frac{t}{t-n}$, the factor thus being 1·5 for a triangle, 1·8 for a hexagon, 2 for a quadrilateral, 2·5 for the network around the Sironj base-line, &c.

In framing the normal equations between the indeterminate factors λ for the final simultaneous reduction, it would have greatly added to the labour of the subsequent calculations if a separate weight had been given to each angle, as was done in the primary figural reductions; this was obviously unnecessary, for theoretical requirements would now be amply satisfied by giving equal weights to all the angles of each independent figure. The mean weight that was finally adopted for the angles of each group was therefore taken as

$$w.\rho\frac{t}{t-n},$$

ρ being the modulus.

The second of the two processes for applying the method of minimum squares having been adopted, the values of the errors y and z of the angles appertaining to any, the pth, triangle were finally expressed by the following equations, which are derived from (10) by substituting u for the reciprocal final mean weight as above determined:—

$$\left.\begin{aligned} y_p &= \frac{u_p}{3}[(2b_p - a_p - c_p)\lambda] \\ z_p &= \frac{u_p}{3}[(2c_p - a_p - b_p)\lambda] \end{aligned}\right\} \qquad (11)$$

The following table gives the number of equations of condition and unknown quantities—the angular errors—in the five great sections of the triangulation, which were respectively included in the simultaneous general reductions and relegated to the subsequent adjustments of each figure *per se*:—

Section.	Simultaneous.			External Figural.					
	Equations.		Angular errors.	Equations.				Angular errors.	No. of figures.
	Circuit and base-line.	Tri-angular.		Tri-angular.	Central.	Side.	Toto-partial.		
1. N.W. Quad.	23	550	1650	267	104	152	6	761	110
2. S.E. Quad.	15	277	831	164	64	92	2	476	68
3. N.E. Quad.	49	573	1719	112	56	69	0	341	50
4. Trigon.	22	303	909	192	79	101	2	547	77
5. S.W. Quad.	24	172	516	83	32	52	1	237	40

The corrections to the angles were generally minute, rarely exceeding the theoretical probable errors of the angles, and therefore applicable without taking any liberties with the facts of observation.

Azimuth Observations.

Azimuth observations in connexion with the principal triangulation were determined by measuring the horizontal angle between a referring mark and a circumpolar star, shortly before and after elongation, and usually at both elongations in order to eliminate the error of the star's place. Systematic changes of "face" and of the zero settings of the azimuthal circle were made as in the measurement of the principal angles; but the repetitions on each zero were more numerous; the azimuthal levels were read and corrections applied to the star observations for dislevelment. The triangulation was not adjusted, in the course of the final simultaneous reduction, to the astronomically determined azimuths, because they are liable to be vitiated by local attractions; but the azimuths observed at about fifty stations around the primary azimuthal station, which was adopted as the origin of the geodetic calculations, were referred to that station, through the triangulation, for comparison with the primary azimuth. A table was prepared of the differences (observed at the origin—computed from a distance) between the primary and the geodetic azimuths; the differences were assumed to be mainly due to the local deflexions of the plumb-line and only partially to error in the triangulation, and each was multiplied by the factor

$$p = \frac{\text{tangent of latitude of origin,}}{\text{tangent of latitude of comparing station}}$$

in order that the effect of the local attraction on the azimuth observed at the distant station—which varies with the latitude and is = the deflexion in the prime vertical $\times$ the tangent of the latitude—might be converted to what it would have been had the station been situated in the same latitude as the origin. Each deduction was given a weight, w, inversely proportional to the number of triangles connecting the station with the origin, and the most probable value of the error of the observed azimuth at the origin was taken as

$$x = \frac{[(\text{observed} - \text{computed})\ p\ w]}{[w]} \qquad (12);$$

the value of x thus obtained was $-1{\cdot}1''$.

The formulae employed in the reduction of the azimuth observations were as follows. In the spherical triangle PZS, in which P is the pole, Z the zenith and S the star, the co-latitude PZ and the polar distance PS are known, and, as the angle at S is a right angle at the elongation, the hour angle and the azimuth at that time are found from the equations

$$\cos P = \tan PS \cot PZ,$$
$$\cos Z = \cos PS \sin P.$$

The interval, δP, between the time of any observation and that of the elongation being known, the corresponding azimuthal angle, δZ, between the two positions of the star at the times of observation and elongation is given rigorously by the following expression —$\tan\delta Z$

$$= -\frac{2\sin^2\frac{1}{2}\delta P}{\cot PS\sin PZ\sin P\{1+\tan^2 PS\cos\delta P+\sec^2 PS\cot P\sin\delta P\}} \qquad (13),$$

which is expressed as follows for logarithmic computation—

$$\delta Z = -\frac{m\tan Z\cos^2 PS}{1-n+l},$$

where $m = 2\sin^2\frac{\delta P}{2}\operatorname{cosec} 1''$, $n = 2\sin^2 PS\sin^2\frac{\delta P}{2}$, and $l = \cot P\sin\delta P$; l, m, and n are tabulated.

Height and Refraction.

Let A and B (fig. 4) be any two points the normals at which meet at C, cutting the sea-level at p and q; take $Dq = Ap$, then BD is the difference of height; draw the tangents Aa and Bb at A and B, then aAB is the depression of B at A and bBA that of A at B; join AD, then BD is determined from the triangle ABD. The triangulation gives the distance between A and B at the sea-level, whence $pq = c$; thus, putting Ap, the height of A above the sea-level, $= H$, and $pC = r$,

$$AD = c\left(1 + \frac{H}{r} - \frac{c^2}{24r^2}\right) \qquad (14).$$

Putting D_a and D_b for the actual depressions at A and B, S for the angle at A, usually called the "subtended angle," and h for BD—

$$S = \tfrac{1}{2}(D_b - D_a) \qquad (15),$$

and

$$h = AD\frac{\sin S}{\cos D_b} \qquad (16).$$

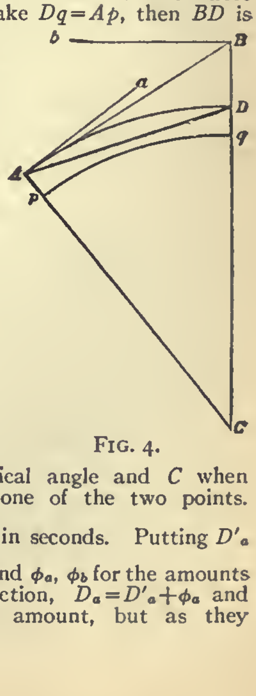

FIG. 4.

The angle at C being $= D_b + D_a$, S may be expressed in terms of a single vertical angle and C when observations have been taken at only one of the two points. C, the "contained arc," $= c\frac{\rho+\nu}{2\rho\nu}\operatorname{cosec} 1''$ in seconds. Putting D'_a and D'_b for the observed vertical angles, and ϕ_a, ϕ_b for the amounts by which they are affected by refraction, $D_a = D'_a + \phi_a$ and $D_b = D'_b + \phi_b$; ϕ_a and ϕ_b may differ in amount, but as they cannot be separately ascertained they are always assumed to be equal; the hypothesis is sufficiently exact for practical purposes when both verticals have been measured under similar atmospheric conditions. The refractions being taken equal, the observed verticals are substituted for the true in (15) to find S, and the difference of height is calculated by (16); the third term within the brackets of (14) is usually omitted. The mean value of the refraction is deduced from the formula

$$\phi=\tfrac{1}{2}\{C-D'_a+D'_b\} \qquad (17).$$

An approximate value is thus obtained from the observations between the pairs of reciprocating stations in each district, and the corresponding mean "coefficient of refraction," $\phi \div C$, is computed for the district, and is employed when heights have to be determined from observations at a single station only. When either of the vertical angles is an elevation $-E$ must be substituted for D in the above expressions.[1]

2. Levelling

Levelling is the art of determining the relative heights of points on the surface of the ground as referred to a hypothetical surface which cuts the direction of gravity everywhere at right angles. When a line of instrumental levels is begun at the sea-level, a series of heights is determined corresponding to what would be found by perpendicular measurements upwards from the surface of water communicating freely with the sea in underground channels; thus the line traced indicates a hypothetical prolongation of the surface of the sea inland, which is everywhere conformable to the earth's curvature.

The trigonometrical determination of the relative heights of points at known distances apart, by the measurements of their mutual vertical angles—is a method of levelling. But the method to which the term "levelling" is always applied is that of the direct determination of the differences of height from the readings of the lines at which graduated staves, held vertically over the points, are cut by the horizontal plane which passes through the eye of the observer. Each method has its own advantages. The former is less accurate, but best suited for the requirements of a general geographical survey, to obtain the heights of all the more prominent objects on the surface of the ground, whether accessible or not. The latter may be conducted with extreme precision, and is specially valuable for the determination of the relative levels, however minute, of easily accessible points, however numerous, which succeed each other at short intervals apart; thus it is very generally undertaken *pari passu* with geographical surveys to furnish lines of level for ready reference as a check on the accuracy of the trigonometrical heights. In levelling with staves the measurements are always taken from the horizontal plane which passes through the eye of the observer; but the line of levels which it is the object of the operations to trace is a curved line, everywhere conforming to the normal curvature of the earth's surface, and deviating more and more from the plane of reference as the distance from the station of observation increases. Thus, either a correction for curvature must be applied to every staff reading, or the instrument must be set up at equal distances from the staves; the curvature correction, being the same for each staff, will then be eliminated from the difference of the readings, which will thus give the true difference of level of the points on which the staves are set up.

Levelling has to be repeated frequently in executing a long line of levels—say seven times on an average in every mile—and must be conducted with precaution against various errors. Instrumental errors arise when the visual axis of the telescope is not perpendicular to the axis of rotation, and when the focusing tube does not move truly parallel to the visual axis on a change of focus. The first error is eliminated, and the second avoided, by placing the instrument at equal distances from the staves; and as this procedure has also the advantage of eliminating the corrections for both curvature and refraction, it should invariably be adopted.

[1] In topographical and levelling operations it is sometimes convenient to apply small corrections to observations of the height for curvature and refraction simultaneously. Putting d for the distance, r for the earth's radius, and κ for the coefficient of refraction, and expressing the distance and radius in miles and the correction to height in feet, then correction for curvature $=\tfrac{2}{3}d^2$; correction for refraction $= -\tfrac{4}{3}\kappa d^2$; correction for both $=\dfrac{2-4\kappa}{3}.d^2$.

Errors of staff readings should be guarded against by having the staves graduated on both faces, but differently figured, so that the observer may not be biased to repeat an error of the first reading in the second. The staves of the Indian survey have one face painted white with black divisions—feet, tenths and hundredths—from 0 to 10, the other black with white divisions from 5·55 to 15·55. Deflexion from horizontality may either be measured and allowed for by taking the readings of the ends of the bubble of the spirit-level and applying corresponding corrections to the staff readings, or be eliminated by setting the bubble to the same position on its scale at the reading of the second staff as at that of the first, both being equidistant from the observer.

Certain errors are liable to recur in a constant order and to accumulate to a considerable magnitude, though they may be too minute to attract notice at any single station, as when the work is carried on under a uniformly sinking or rising refraction—from morning to midday or from midday to evening—or when the instrument takes some time to settle down on its bearings after being set up for observation. They may be eliminated (i.) by alternating the order of observation of the staves, taking the back staff first at one station and the forward first at the next; (ii.) by working in a circuit, or returning over the same line back to the origin; (iii.) by dividing a line into sections and reversing the direction of operation in alternate sections. Cumulative error, not eliminable by working in a circuit, may be caused when there is much northing or southing in the direction of the line, for then the sun's light will often fall endwise on the bubble of the level, illuminating the outer edge of the rim at the nearer end and the inner edge at the farther end, and so biasing the observer to take scale readings of edges which are not equidistant from the centre of the bubble; this introduces a tendency to raise the south or depress the north ends of lines of level in the northern hemisphere. On long lines, the employment of a second observer, working independently over the same ground as the first, station by station, is very desirable. The great lines are usually carried over the main roads of the country, a number of "bench marks" being fixed for future reference. In the ordnance survey of Great Britain lines have been carried across from coast to coast in such a manner that the level of any common crossing point may be found by several independent lines. Of these points there are 166 in England, Scotland and Wales; the discrepancies met with at them were adjusted simultaneously by the method of minimum squares.

Sea-level.

The sea-level is the natural datum plane for levelling operations, more particularly in countries bordering on the ocean. The earliest surveys of coasts were made for the use of navigators and, as it was considered very important that the charts should everywhere show the minimum depth of water which a vessel would meet with, low water of spring-tides was adopted as the datum. But this does not answer the requirements of a land survey, because the tidal range between extreme high and low water differs greatly at different points on coast-lines. Thus the generally adopted datum plane for land surveys is the mean sea-level, which, if not absolutely uniform all the world over, is much more nearly so than low water. Tidal observations have been taken at nearly fifty points on the coasts of Great Britain, which were connected by levelling operations; the local levels of mean sea were found to differ by larger magnitudes than could fairly be attributed to errors in the lines of level, having a range of 12 to 15 in. above or below the mean of all at points on the open coast, and more in tidal rivers.[2] But the general mean of the coast stations for England and Wales was practically identical with that for Scotland. The observations, however, were seldom of longer duration than a fortnight, which is insufficient for an exact determination of even the short period components of the tides, and ignores the annual and semi-annual components, which occasionally attain considerable magnitudes. The mean sea-levels at Port Said in the Mediterranean and at Suez in the Red Sea have been found to be identical, and a similar identity is said to exist in the levels of the Atlantic and the Pacific oceans on the opposite coasts of the Isthmus of Panama. This is in favour of a uniform level all the world over; but, on the other hand, lines of level carried across the continent of Europe make the mean sea-level of the Mediterranean at Marseilles and Trieste from 2 to 5 ft. below that of the North Sea and the Atlantic at Amsterdam and Brest—a result which

[2] In tidal estuaries and rivers the mean water-level rises above the mean sea-level as the distance from the open coast-line increases; for instance, in the Hooghly river, passing Calcutta, there is a rise of 10 in. in 42 m. between Sagar (Saugor) Island at the mouth of the river and Diamond Harbour, and a further rise of 20 in. in 43 m. between Diamond Harbour and Kidderpur.

it is not easy to explain on mechanical principles. In India various tidal stations on the east and west coasts, at which the mean sea-level has been determined from several years' observations, have been connected by lines of level run along the coasts and across the continent; the differences between the results were in all cases due with greater probability to error generated in levelling over lines of great length than to actual differences of sea-level in different localities.

The sea-level, however, may not coincide everywhere with the geometrical figure which most closely represents the earth's surface, but may be raised or lowered, here and there, under the influence of local and abnormal attractions, presenting an equipotential surface—an ellipsoid or spheroid of revolution slightly deformed by bumps and hollows—which H. Bruns calls a "geoid." Archdeacon Pratt has shown that, under the combined influence of the positive attraction of the Himalayan Mountains and the negative attraction of the Indian Ocean, the sea-level may be some 560 ft. higher at Karachi than at Cape Comorin; but, on the other hand, the Indian pendulum operations have shown that there is a deficiency of density under the Himalayas and an increase under the bed of the ocean, which may wholly compensate for the excess of the mountain masses and deficiency of the ocean, and leave the surface undisturbed. If any bumps and hollows exist, they cannot be measured, instrumentally; for the instrumental levels will be affected by the local attractions precisely as the sea-level is, and will thus invariably show level surfaces even should there be considerable deviations from the geometrical figure.

Geoid or Deformed Surface.

3. Topographical Surveys

The skeleton framework of a survey over a large area should be triangulation, although it is frequently combined with traversing. The method of filling in the details is necessarily influenced to some extent by the nature of the framework, but it depends mainly on the magnitude of the scale and the requisite degree of minutiae. In all instances the principal triangles and circuit traverses have to be broken down into smaller ones to furnish a sufficient number of fixed points and lines for the subsequent operations. The filling in may be performed wholly by linear measurements or wholly by direction intersections, but is most frequently effected by both linear and angular measures, the former taken with chains and tapes and offset poles, the latter with small theodolites, sextants, optical squares or other reflecting instruments, magnetized needles, prismatic compasses and plane tables. When the scale of a survey is large, the linear and angular measures are usually recorded on the spot in a field-book and afterwards plotted in office; when small they are sometimes drawn on the spot on a plane table and the field-book is dispensed with.

In every country the scale is generally expressed by the ratio of some fraction or multiple of the smallest to the largest national units of length, but sometimes by the fraction which indicates the ratio of the length of a line on the paper to that of the corresponding line on the ground. The latter form is obviously preferable, being international and independent of the various units of length adopted by different nations (see Map). In the ordnance survey of Great Britain and Ireland and the Indian survey the double unit of the foot and the Gunter's link ($=\frac{66}{100}$ of a foot) are employed, the former invariably in the triangulation, the latter generally in the traversing and filling in, because of its convenience in calculations and measurements of area, a square chain of 100 Gunter's links being exactly one-tenth of an acre.

In the ordnance survey all linear measures are made with the Gunter's chain, all angular with small theodolites only; neither magnetized nor reflecting instruments nor plane tables are ever employed, except in hill sketching. As a rule the filling in is done by triangle-chaining only; traverses with theodolite and chain are occasionally resorted to, but only when it is necessary to work round woods and hill tracts across which right lines cannot be carried.

Detail surveying by triangles is based on the points of the minor triangulation. The sides are first chained perfectly straight, all the points where the lines of interior detail cross the sides being fixed; the alignment is effected with a small theodolite, and marks are established at the crossing points and at any other points on the sides where they may be of use in the subsequent operations. The surveyor is given a diagram of the triangulation, but no side lengths, as the accuracy of his chaining is tested by comparison with the trigonometrical values. Then straight lines are carried across the intermediate detail between the points established on the sides; they constitute the principal "cutting up or split lines"; their crossings of detail are marked in turn and straight lines are run between them. The process is continued until a sufficient number of lines and marks have been established on the ground to enable all houses, roads, fences, streams, railways, canals, rivers, boundaries and other details to be conveniently measured up to and fixed. Perpendicular offsets are limited to eighty and twenty links for the respective scales of 6 in. to a mile and $\frac{1}{2500}$.

When a considerable area has to be treated by traverses it is divided into a number of blocks of convenient size, bounded by roads, rivers or parish boundaries, and a "traverse on the meridian of the origin" is carried round the periphery of each block. Beginning at a trigonometrical station, the theodolite is set to circle reading 0° 0′ with the telescope pointing to the north, and at every "forward" station of the traverse the circle is set to the same reading when the telescope is pointed at the "back" station as was obtained at the back station when the telescope was pointing to the forward one. When the circuit is completed and the theodolite again put up at the origin and set on the last back station with the appropriate circle reading, the circle reading, with the telescope again pointed to the first forward station, will be the same as at first, if no error has been committed. This system establishes a convenient check on the accuracy of the operations and enables the angles to be readily protracted on a system of lines parallel to the meridian of the origin. As a further check the traverse is connected with all contiguous trigonometrical stations by measured angles and distances. Traverses are frequently carried between the points already fixed on the sides of the minor triangles; the initial side is then adopted, instead of the meridian, as the axis of co-ordinates for the plotting, the telescope being pointed with circle reading 0° 0′ to either of the trigonometrical stations at the extremities of the side.

The plotting is done from the field-books of the surveyors by a separate agency. Its accuracy is tested by examination on the ground, when all necessary addenda are made. The examiner —who should be surveyor, plotter and draughtsman—verifies the accuracy of the detail by intersections and productions and occasional direct measurements, and generally endeavours to cause the details under examination to prove the accuracy of each other rather than to obtain direct proof by remeasurement. He fixes conspicuous trees and delineates the woods, footpaths, rocks, precipices, steep slopes, embankments, &c., and supplies the requisite information regarding minor objects to enable a draughtsman to make a perfect representation according to the scale of the map. In examining a coast-line he delineates the foreshore and sketches the strike and dip of the stratified rocks. In tidal rivers he ascertains and marks the highest points to which the ordinary tides flow. The examiner on the 25·344 in. scale ($=\frac{1}{2500}$) is required to give all necessary information regarding the parcels of ground of different character—whether arable, pasture, wood, moor, moss, sandy—defining the limits of each on a separate tracing if necessary. He has also to distinguish between turnpike, parish and occupation roads, to collect all names, and to furnish notes of military, baronial and ecclesiastical antiquities to enable them to be appropriately represented in the final maps. The latter are subjected to a double examination—first in the office, secondly on the ground; they are then handed over to the officer in charge of the levelling to have the levels and contour lines inserted, and finally to the hill sketchers, whose duty it is to make an artistic representation of the features of the ground.

In the Indian survey all filling in is done by plane-tabling on a basis of points previously fixed; the methods differ simply in the extent to which linear measures are introduced to supplement the direction rays of the plane-table. When the scale of the survey is small, direct measurements of distance are rarely made and the filling is usually done wholly by direction intersections, which fix all the principal points, and by eye-sketching; but as the scale is increased linear measures with chains and offset poles are introduced to the extent that may be desirable. A sheet of drawing paper is mounted on cloth over the face of the plane-table; the points, previously fixed by triangulation or otherwise, are projected on it—the collateral meridians and parallels, or the rectangular co-ordinates, when these are more convenient for employment than the spherical, having first been drawn; the plane-table is then ready for use. Operations are begun at a fixed point by aligning with the sight rule on another fixed point, which brings the meridian line of the table on that of the station. The magnetic needle may now be placed on the table and a position assigned to it for future reference. Rays are drawn from the station point on the table to all conspicuous objects around with the aid of the sight rule. The table is then taken to other fixed points, and the process of ray-drawing is repeated at each; thus a number of objects, some of which may become available as stations of observation, are fixed. Additional stations may be established by setting up the table on a ray, adjusting it on the back station—that from which the ray was drawn—and then obtaining a cross intersection with the sight rule laid on some other fixed point, also by interpolating between three fixed points situated around the observer. The magnetic needle may not be relied on for correct orientation, but is of service in enabling the table to be set so nearly true at the outset that it has to be very slightly altered afterwards. The error in the setting is indicated by the rays from the surrounding fixed points intersecting in a small triangle instead of a point, and a slight change in azimuth suffices to reduce the triangle to a point, which will indicate the position of the station exactly. Azimuthal error being less apparent on short than on long lines, interpolation is best performed by rays drawn from near points, and checked by rays drawn to distant points, as the latter show most strongly the magnitude of any error of the primary magnetic setting. In this way, and by self-verificatory traverses "on the back ray" between fixed points, plane-table stations are established over the ground at appropriate intervals, depending on the scale of the survey; and from these stations all surrounding objects which the scale permits of being shown are laid down on the table, sometimes by rays only, sometimes by a single ray and a measured distance. The general configuration of the ground is delineated simultaneously. In *checking and examination* various methods are followed. For large scale work in plains it is customary to run arbitrary lines across it and make an independent survey of the belt of ground to a distance of a few chains on either side for comparison with the original survey; the smaller scale hill topography is checked by examination from commanding points, and also by traverses run across the finished work on the table.

4. Geographical Surveying

The introduction by mechanical means of superior graduation in instruments of the smaller class has enabled surveyors to effect good results more rapidly, and with less expenditure on equipment and on the staff necessary for transport in the field, than was formerly possible. The 12-in. theodolite of the present day, with micrometer adjustments to assist in the reading of minute subdivisions of angular graduation, is found to be equal to the old 24-in. or even 36-in. instruments. New Methods for the measurement of bases have largely superseded the laborious process of measurement by the alignment of "compensation" bars, though not entirely independent of them. The Jäderin apparatus, which consists of a wire 25 metres in length stretched along a series of cradles or supports, is the simplest means of measuring a base yet devised; and experiments with it at the Pulkova observatory show it to be capable of producing most accurate results. But there is a measurable defect in the apparatus, owing to the liability of the wires to change in length under variable conditions of temperature. It is therefore considered necessary, where base measurements for geodetic purposes are to be made with scientific exactness, that the Jäderin wires should be compared before and after use with a standard measurement, and this standard is best attained by the use of the Brunner, or Colby, bars. The direct process of measurement is not extended to such lengths as formerly, but from the ends of a shorter line, the length of which has been exactly determined, the base is extended by a process of triangulation.

Base Measurements.

There are vast areas in which, while it is impossible to apply the elaborate processes of first-class or "geodetic" triangulation, it is nevertheless desirable that we should rapidly acquire such geographical knowledge as will enable us to lay down political boundaries, to project roads and railways, and to attain such exact knowledge of special localities as will further military ends. Such surveys are called by various names—military surveys, first surveys, geographical surveys, &c.; but, inasmuch as they are all undertaken with the same end in view, *i.e.* the acquisition of a sound topographical map on various scales, and as that end serves civil purposes as much as military, it seems appropriate to designate them geographical surveys only.

Secondary Triangulation.

The governing principles of geographical surveys are rapidity and economy. Accuracy is, of course, a recognized necessity, but the term must admit of a certain elasticity in geographical work which is inadmissible in geodetic or cadastral functions. It is obviously foolish to expend as much money over the elaboration of topography in the unpeopled sand wastes which border the Nile valley, for instance (albeit those deserts may be full of topographical detail), as in the valley itself—the great centre of Egyptian cultivation, the great military highway of northern Africa. On the other hand, the most careful accuracy attainable in the art of topographical delineation is requisite in illustrating the nature of a district which immediately surrounds what may prove hereafter to be an important military position. And this, again, implies a class of technical accuracy which is quite apart from the rigid attention to detail of a cadastral survey, and demands a much higher intelligence to compass.

Principles which govern Geographical Surveys.

The technical principles of procedure, however, are the same in geographical as in other surveys. A geographical survey must equally start from a base and be supported by triangulation, or at least by some process analogous to triangulation, which will furnish the necessary skeleton on which to adjust the topography so as to ensure a complete and homogeneous map.

Methods of Survey.

This base may be found in a variety of ways. If geodetic triangulation exists in the country, that triangulation should of course include a wide extent of secondary determinations, the fixing of peaks and points in the landscape far away to either flank, which will either give the data for further extension of geographical triangulation, or which may even serve the purposes of the map-maker without any such extension at all. In this manner the Indus valley series of the triangulation of India has furnished the basis for surveys across Afghanistan and Baluchistan to the Oxus and Persia.

The Base.

Should no such preliminary determinations of the value of one or two starting-points be available, and it becomes necessary to measure a base and to work *ab initio*, the Jäderin wire apparatus may be adopted. It is cheap (cost about £50), and far more accurate than the process of measuring either by any known "subtense" system (in which the distance is computed from the angle subtended by a bar of given length) or by measurement with a steel chain. This latter method may, however, be adopted so long as the base can be levelled, repeated measurements obtained, and the chain compared with a standard steel tape before and after use.

The initial data on which to start a comprehensive scheme of triangulation for a geographical survey are: (1) latitude; (2) longitude; (3) azimuth; and (4) altitude, and this data should, if possible, be obtained *pari passu* with the measurement of the base.

Initial Data.

A 6-in. transit theodolite, fitted with a micrometer eyepiece and extra vertical wires, is the instrument *par excellence* for work of this nature; and it possesses the advantages of portability and comparative cheapness.

The method of using it for the purposes of determining values for (1) and (3), *i.e.* for ascertaining the latitude of one end of the base and the azimuth of the other end from it, are fully explained in Major Talbot's paper on *Military Surveying in the Field* (J. Mackay & Co., Chatham, 1889), which is not a theoretical treatise, but a practical illustration of methods employed successfully in the geographical survey of a very large area of the Indian transfrontier districts. It should be noted that these observations are not merely of an initial character. They should be constantly repeated as the survey advances, and under certain circumstances (referred to subsequently) they require daily repetition.

Latitude and Azimuth.

The problems connected with the determination of (2) longitude have of late years occupied much of the attention of scientific surveyors. No system of absolute determination is accurate enough for combination with triangulation, as affording a check on the accuracy of the latter, and the spaces in the world across which geographical surveying has yet to be carried are rapidly becoming too restricted to admit of any liability to error so great as is invariably involved in such determinations. It is true that absolute values derived from the observation of lunar distances, or occultations, have often proved to be of the highest value; but there remains a degree of uncertainty (possibly due to the want of *exact* knowledge of the moon's position at any instant of time), even when observations have been taken with all the advantages of the most elaborate arrangements and the most scientific manipulation, which renders the roughest form of triangulation more trustworthy for ascertaining differential longitude than any comparison between the absolute determination of any two points. Consequently, if an absolute determination is necessary it should be made *once*, with all possible care, and the value obtained should be carried through the whole scheme of triangulation. It rests with the surveyor to decide at what point of the general survey this value can best be introduced, provided he

Longitude.

can estimate the probable longitudinal value of his initial base within a few minutes of the truth. A final correction in longitude is constant, and can easily be applied. With reference to such absolute determinations of longitude, Major S. Grant's "Diagram for determining the parallaxes in declination and right ascension of a heavenly body and its application to the prediction of occultations" (*Roy. Geog. Soc. Journ.* for June 1896) will afford the observer valuable assistance.

Telegraph Determinations. But the recognized method of obtaining a longitude value in recent geographical fields is by means of the telegraph—a method so simple and so accurate that it may be applied with advantage even to the checking of long lines of triangulation. No effort should be spared to introduce a telegraphic longitude value into any scheme of geographical survey. It involves a clear line and an instructed observer at each end, but, given these desiderata, the interchange of time signals sufficient for an accurate record only requires a night or two of clear weather. But inasmuch as rigorous accuracy in the observations for time is necessary, it would be well for the surveyor in the field to be provided with a sidereal chronometer. Under all other circumstances demanding time observations (and they are an essential supplement to every class of astronomical determination) an ordinary mean time watch is sufficient.

Altitude. With reference to altitude determinations, there has lately been observable amongst surveyors a growing distrust of barometric results and a reaction in favour of direct levelling, or of differential results derived from direct observation with the theodolite (or clinometer) rather than from comparison of those determined by aneroid or hypsometer. It is indeed impossible to eliminate the uncertainties due to the variable atmospheric pressure introduced by "weather" changes from any barometric record. A mercurial barometer advantageously placed and carefully observed at fixed diurnal intervals throughout a comparatively long period may give fairly trustworthy results if a constant comparison can be maintained throughout that period with similar records at sea-level, or at any fixed altitude. Yet observations extending over several months have been found to yield results which compare most unfavourably with those attained during the process of triangulation by continued lines of vertical observations from point to point, even when the uncertainties of the correction for refraction are taken into account. Errors introduced into vertical observations by refraction are readily ascertainable and comparatively unimportant in their effect. Those due to variable atmospheric conditions on barometric records are still indefinite, and are likely to remain so. The result has been that the latter have been relegated to purely local conditions of survey, and that whenever practicable the former are combined with the general process of triangulation.

Conditions under which Geographical Surveys are carried out. The conditions under which geographical surveys can be carried out are of infinite variety, but those conditions are rare which absolutely preclude the possibility of any such surveys at all. Perfect freedom of action, and the recognition of such work as a public benefit, are not often attainable. Far more frequently the opportunity offers itself to the surveyor with the progress of a political mission or the advance of an army in the field. It cannot be too strongly insisted on that geographical surveys are functions of both civil and military operations. Very much of such work is also possible where a country lies open to exploration, not actively hostile, but yet unsettled and adverse to strangers. The geographical surveyor has to fit himself to all such conditions, and it may happen that a continuous, comprehensive scheme of triangulation as a map basis is impossible. Under such circumstances other expedients must be adopted to ensure that accuracy of position which cannot be attained by the topographer unaided.

Route Surveying. During a long-continued march extending through a line of country generally favourable for survey purposes—a condition which frequently occurs—when forward movement is a necessity, and an average of 10 to 15 m. of daily progress is maintained, one officer and an assistant can measure a daily base, obtain the necessary astronomical determinations, triangulate from both ends so as to fix the azimuth and distance from the base of points passed yesterday and those to be passed to-morrow; project those points on to the topographer's plane-table to be ready for the next day's work, and check each day's record by latitude; whilst a second assistant runs the topography through the route, basing his work on points so fixed, on the scale of 2 or 4 m. to the inch, according to the amount of detail. Occasionally a hill can be reached in the course of the day's march, or during a day's halt, which will materially assist to consolidate and strengthen the series.

Triangulation or Control. It may, however, frequently be impossible to maintain a consistent series of triangulation for the "control" (to use an American expression) of the topography, even when the configuration of the land surface is favourable. In such circumstances the method of observing azimuths to points situated approximately near to the probable route in advance, and of determining the exact position of those points in latitude as one by one they are passed by the moving force, has been found to yield results which are quite sufficiently accurate to ensure the final adjustment of the entire route geography to any subsequent system of triangulation which may be extended through the country traversed, without serious discrepancies in compilation. It is, however, obvious that as accuracy depends greatly on the exact determination of absolute latitude values, this method is best adapted to a route running approximately parallel to a meridian, and is at complete disadvantage in one running east and west. Where the conditions are favourable to its application, it has been adopted with most satisfactory results; as, for instance, on the route between Seistan and Herat, where the initial data for the Russo-Afghan boundary delimitation was secured by this means, and more recently on the boundary surveys of western Abyssinia.

Military Geography. When an active enemy is in the field, and topographical operations are consequently restricted, it is usually possible to obtain the necessary "control" (*i.e.* a few well-fixed points determined by triangulation) for topography in advance of a position securely held. With a very little assistance from the triangulator an experienced topographer will be able to sketch a field of action with far more certainty and rapidity than can be attained by the ordinary so-called "military surveyor," and he may, in favourable circumstances, combine his work with that of the military balloonist in such a way as to represent every feature of importance, even in a widely extended position held by the enemy. The application of the camera and of telephotography to the evolution of a map of the enemy's position is well understood in France (*vide* Colonel Laussedat's treatise on "The History of Topography"), as it is in Russia, and we must in future expect that all advantages of an expert and professional map of the whole theatre of a campaign will lie in the hands of the general who is best supplied with professional experts to compass them. Geographical surveying and military surveying are convertible terms, and it is important to note that both equally require the services of a highly trained staff of professional topographers. During the war between Russia and Turkey (1877–78) upwards of a hundred professional geographical surveyors were pressed into military service, besides the regular survey staff which is attached to every army corps. Triangulation was carried across the Balkans by eight different series; every pass and every notable feature of the Balkans and Rhodope Mountains was accurately surveyed, as well as the plains intervening between the Balkans and Constantinople. Surveys on a scale which averaged about 1 m. = 1 in. were carried up to the very gates of the city.

Photo-topography. The use of the camera as an accessory to the plane table (*i.e.* the art of photo-topography) has been applied almost exclusively to geographical or exploratory surveys. The camera is specially prepared, resting on a graduated horizontal plate which is read with verniers, and with a small telescope and vertical arc attached. Cross wires are fixed in the focal plane of the camera, which is also fitted with a magnetic needle and a scale so placed that the magnetic declination, the scale, and the intersection of the cross wires are all photographed on the plate containing the view. A panoramic group of views (slightly overlapping each other) is taken at each station, and the angular distance between each is measured on the horizontal circle. The process of constructing the horizontal projection from these perspective views involves plotting the skeleton triangulation, as obtained from the primary triangulation, with the theodolite (which precedes the photo-topographical survey), or from the horizontal plate of the camera. With several stations so plotted, the view from each of them of a certain portion of the country may be projected on the plane of the map, and salient points seen in perspective may be fixed by intersection.

The field work of a photo-topographic party consists primarily in execution of a triangulation by the usual methods which would be adapted to any ordinary topographical survey. To this is added a secondary triangulation, which is executed *pari passu* with the photography for the purpose of fixing the position of the camera stations. From such stations alone the topographical details are finally secured with the aid of the photographs. Great care is necessary in the selection of stations that will be suitable both for the extension of triangulation and the purposes of closely overlooking topographical details. In order to obtain means for correctly orienting the photographic views when plotting the map from them, it is usual, whilst making the exposures, to observe two or three points in each view with the alt-azimuth attached to the camera, in order to ascertain the horizontal and vertical angles between them. It is also advisable to keep an outline sketch of the landscape for the purpose of recording names of roads, buildings, &c.

The process of projecting the map from the photographs involves the use of two drawing-boards, on one of which the graphical determination of the points is made, and on the other the details of the final topography are drawn. The principal trigonometrical points are plotted on both these boards by their co-ordinates, and the camera stations either by their co-ordinate values or by intersection. Intermediate points, selected as appearing on two or more negatives, are then projected by intersection. The horizontal projection of a panorama consisting of any given number of plates is a regular geometrical figure of as many sides as there are plates, enclosing an inscribed circle whose radius is the focal length of the camera. Having correctly plotted the position of one plate, or view, with reference to the projected camera station by means of the angle observed to some known point within it, it is possible to plot the position of the rest of the series, with reference to the camera station and the orienting triangulation point, by the angular differences which are dependent on the number of photographs forming the sides of the geometrical figure. Having secured the correct orientation of the horizontal plan, direction lines are drawn from the plotted camera station to points photographed, and the position of topographical features is fixed by intersection from two or more camera stations.

Plane-table. The plane-table is the instrument, *par excellence*, on which the geographical surveyor must depend for the final mapping of the physical features of the country under survey. The methods of adapting the plane-table to geographical requirements differ with those varying climatic conditions which affect its construction. In the comparatively dry climate of Asiatic Russia or of the United States, where errors arising from the unequal expansion of the plane-table board are insignificant, the plane-table is largely made use of as a triangulating instrument, and is fitted with slow-motion screws and with other appliances for increasing the certainty and the accuracy of observations. Such an adaptation of the plane-table is found to be impossible in India, where the great alternations of temperature, no less than of atmospheric humidity, tend to vitiate the accuracy of the projections on the surface of the board by the unequal effects of expansion in the material of which it is composed. The Indian plane-table is of the simplest possible construction, and it is never used in connexion with the stadia for ascertaining the distances of points and features of the ground (as is the case in America); and in place of the complicated American alidade, with its telescope and vertical arc, a simple sight rule is used, and a chirometer for the measurement of vertical angles. The Indian plane-table approximates closely in general construction to the "Gannett" pattern of America, which is specially constructed for exploratory surveys.

Scale. The scale on which geographical surveys are conducted is necessarily small. It may be reckoned at from 1 : 500000 to 1 : 125000, or from 1 in. = 8 m. to 1 in. = 2 m. The 1 in. = 1 m. scale is the normal scale for rigorous topography, and although it is impossible to fix a definite line beyond which geographical scales merge into topographical (for instance, the 1-in. scale is classed as geographical in America whenever the continuous line contour system of ground representation gives place to hachuring), it is convenient to assume generally that geographical scales of mapping are smaller than the 1-in. scale.

Out-turn. On the smaller scales of 1 : 500000 or 1 : 250000 an experienced geographical surveyor, in favourable country, will complete an area of mapping from day to day which will practically cover nearly all that falls within his range of vision; and he will, in the course of five or six months of continuous travelling (especially if provided with the necessary "control") cover an area of geographical mapping illustrating all important topographical features representable on the small scale of his survey, which may be reckoned at tens of thousands of square miles. But inasmuch as everything depends upon his range of vision, and the constant occurrence of suitable features from which to extend it, there is obviously no guiding rule by which to reckon his probable out-turn.

Cost. The same uncertainty which exists about "out-turn" manifestly exists about "cost." The normal cost of the 1-in. rigorous topographical survey in India, when carried over districts which present an average of hills, plains and forests, may be estimated as between 35 to 40 shillings a square mile. This compares favourably with the rates which obtain in America over districts which probably present far more facilities for surveying than India does, but where cheap native labour is unknown. The geographical surveyor is simply a topographer employed on a smaller scale survey. His equipment and staff are somewhat less, but, on the other hand, his travelling expenses are greater. It is found that, on the whole, a fair average for the cost of geographical work may be struck by applying the square of the unit of scale as a factor to 1-in. survey rates; thus a quarter-inch scale survey (*i.e.* 4 m. to the in.), should be one-sixteenth of the cost per mile of the 1-in. survey over similar ground. A geographical reconnaissance on the scale of 1 : 500000 (8 m. = 1 in.) should be one-sixty-fourth of the square-mile cost of the 1-in. survey, &c. This is, indeed, a close approximation to the results obtained on the Indian transfrontier, and would probably be found to hold good for British colonial possessions.

Map Reproduction. In processes of map reproduction an invention for the reproduction of drawings by a method of direct printing on zinc without the intervention of a negative has proved of great value. By this method a considerable quantity of work has been turned out in much less time and at a much lower cost than would be involved by any process of photo-zincography or lithography. A large number of cadastral maps have been reproduced at about one-ninth of the ordinary cadastral rate.

For the rapid reproduction of geographical maps in the field in order to meet the requirements of a general conducting a campaign, or of a political officer on a boundary mission, no better method has been evolved than the ferrotype process, by which blue prints can be secured in a few hours from a drawing of the original on tracing-cloth. The sensitized paper and printing-frame are far more portable than any photo-lithographic apparatus. Sketches illustrative of a field of action may be placed in the hands of the general commanding on the day following the action, if the weather conditions are favourable for their development. The necessity for darkness whilst dealing with the sensitized material is a drawback, but it may usually be arranged with blankets and waterproof sheets when a tent is not available.

5. Traversing and Fiscal, or Revenue, Surveys

Traversing is a combination of linear and angular measures in equal proportions; the surveyor proceeds from point to point, measuring the lines between them and at each point the angle between the back and forward lines; he runs his lines as much as possible over level and open ground, avoiding obstacles by working round them. The system is well suited for laying down roads, boundary lines, and circuitous features of the ground, and is very generally resorted to for filling in the interior details of surveys based on triangulation. It has been largely employed in certain districts of British India, which had to be surveyed in a manner to satisfy fiscal as well as topographical requirements; for, the village being the administrative unit of the district, the boundary of every village had to be laid down, and this necessitated the survey of an enormous number of circuits. Moreover, the traverse system was better adapted for the country than a network of triangulation, as the ground was generally very flat and covered with trees, villages, and other obstacles to distant vision, and was also devoid of hills and other commanding points of view. The principal triangulation had been carried across it, but by chains executed with great difficulty and expense, and therefore at wide intervals apart, with the intention that the intermediate spaces should be provided with points as a basis for the general topography in some other way. A system of traverses was obviously the best that could be adopted under the circumstances, as it not only gave all the village boundaries, but was practically easier to execute than a network of minor triangulation.

In the Indian survey the traverses are executed in minor circuits following the periphery of each village and in major circuits comprising groups of several villages; the former are done with 4″ to 6″ theodolites and a single chain, the latter with 7″ to 10″ theodolites and a pair of chains, which are compared frequently with a standard. The main circuits are connected with every station of the principal triangulation within reach. The meridian of the origin is determined by astronomical observations; the angle at the origin between the meridian and the next station is measured, and then at each of the successive stations the angle between the immediately preceding and following stations; summing these together, the "inclinations" of the lines between the stations to the meridian of the origin are successively determined. The distances between the stations, multiplied by the cosines and sines of the inclinations, give the distance of each station from the one preceding it, resolved in the directions parallel and perpendicular respectively to the meridian of the origin; and the algebraical sums of these quantities give the corresponding rectangular co-ordinates of the successive stations relatively to the origin and its meridian. The area included in any circuit is expressed by the formula

area = half algebraical sum of products $(x_1+x_2)\ (y_2-y_1)$ (18),

x_1, y_1 being the co-ordinates of the first, and x_2, y_2 those of the second station, of every line of the traverse in succession round the circuit.

Of geometrical tests there are two, both applicable at the close of a circuit: the first is angular, viz. the sum of all the interior angles of the described polygon should be equal to twice as many right angles as the figure has sides, less four; the second is linear, viz. the algebraical sum of the x co-ordinates and that of the y co-ordinates should each be $=0$. The astronomical test is this: at any station of the traverse the azimuth of a referring mark may be determined by astronomical observations; the inclination of the line between the station and the referring mark to the meridian of the origin is given by the traverse; the two should differ by the convergency of the meridians of the station and the origin. In practice the angles of the traverse are usually adjusted to satisfy their special geometrical and astronomical tests in the first instance, and then the co-ordinates of the stations are calculated and adjusted by corrections applied to the longest, that the angles may be least disturbed, as no further corrections are given them.

Convergency of Meridians.

The exact value of the convergence, when the distance and azimuth of the second astronomical station from the first are known, is that of $B-(\pi+A)$ of equation (5); but, as the first term is sufficient for a traverse, we have

$$\text{convergency} = x \tan \lambda \frac{\operatorname{cosec} 1''}{\nu},$$

substituting x, the co-ordinate of the second station perpendicular to the meridian of the origin, for $c \sin A$.

Adjustment of Traverses to Triangulation.

The co-ordinates of the principal stations of a trigonometrical survey are usually the spherical co-ordinates of latitude and longitude; those of a traverse survey are always rectangular, plane for a small area but spherical for a large one. It is often necessary, therefore, for purposes of comparison and check at stations common to surveys of both descriptions, to convert either rectangular co-ordinates into latitudes and longitudes, or vice versa, in order that the errors of traverses may be dispersed by proportion over the co-ordinates of the traverse stations, if desired, or adjusted in the final mapping. The latter is generally all that is necessary, more particularly when the traverses are referred to successive trigonometrical stations as origins, as the operations are being extended, in order to prevent any large accumulation of error. Similar conversions are also frequently necessary in map projections. The method of effecting them will now be indicated.

Transformation of Co-ordinates.

Let A and B be any two points, Aa the meridian of A, Bb the parallel of latitude of B; then Ab, Bb will be their differences in latitude and longitude; from B draw BP perpendicular to Aa; then AP, BP will be the rectangular spherical co-ordinates of B relatively to A. Put $BP=x$, $AP=y$, the arc $Pb=\eta$, and the arc Bb, the difference of longitude, $=\omega$; also let λ_a, λ_b and λ_p be the latitudes of A, B, and the point P, ρ_p the radius of curvature of the meridian, and ν_p the normal terminating in the axis minor for the latitude λ_p; and let ρ_0 be the radius of curvature for the latitude $\frac{1}{2}(\lambda_a+\lambda_p)$. Then, when the rectangular co-ordinates are given, we have, taking A as the origin, the latitude of which is known,

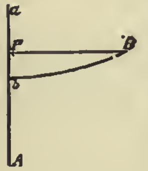

FIG. 5.

$$\left.\begin{aligned} \lambda_p &= \lambda_a + \frac{y}{\rho_0}\operatorname{cosec} 1''; \quad \eta = \frac{x^2}{2\rho_p\nu_p}\tan \lambda_p \operatorname{cosec} 1''; \\ \lambda_b - \lambda_a &= \frac{y}{\rho_0}\operatorname{cosec} 1'' - \eta; \quad \omega = \frac{x}{\nu_p}\sec(\lambda_b + \tfrac{1}{3}\eta) \operatorname{cosec} 1'' \end{aligned}\right\} \quad (19).$$

And, when the latitude and longitude are given, we have [1]

$$\left.\begin{aligned} \eta &= \left(\frac{\omega}{2}\right)^2 \frac{\nu_b}{\rho_b} \sin 2\lambda_b \sin 1'' \\ y &= \rho_0\{\lambda_b - \lambda_a + \eta\} \sin 1'' \\ x &= \omega\nu_p \cos(\lambda_b + \tfrac{1}{3}\eta) \sin 1'' \end{aligned}\right\} \quad (20).$$

Co-ordinates of Unvisited Point.

When a hill peak or other prominent object has been observed from a number of stations whose co-ordinates are already fixed, the converging rays may be projected graphically, and from an examination of their several intersections the most probable position of the object may be obtained almost as accurately as by calculations by the method of least squares, which are very laborious and out of place for the determination of a secondary point. The following is a description of the application of this method to points on a plane surface in the calculations of the ordnance survey. Let s_1, s_2, . . . be stations whose rectangular co-ordinates, x_1, x_2, . . . perpendicular, and y_1, y_2, . . . parallel, to the meridian of the origin are given; let a_1, a_2, . . . be the bearings—here the direction-inclinations with the meridian of the origin—of any point P, as observed at the several stations; and let p be an approximate position of P, with co-ordinates x_p, y_p, as determined by graphical projection on a district map or by rough calculation. Construct a diagram of the rays converging around p, by taking a point to represent p and drawing two lines through it at right angles to each other to indicate the directions of north, south, east and west. Calculate accurately $(y_p-y_1)\tan a_1$, and compare with (x_p-x_1); the difference will show how far the direction of the ray from s_1 falls to the east or west of p. Or calculate $(x_p-x_1)\cot a_1$, and compare with (y_p-y_1) to find how far the direction falls to the north or south of p. Set off the distance on the corresponding axis of p, and through

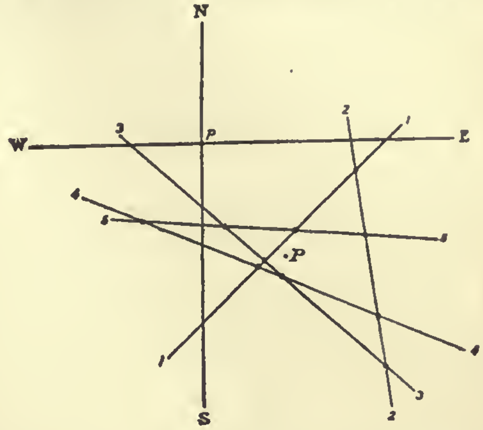

FIG. 6.

the point thus fixed draw the direction a_1 with a common protractor. All the other rays around p may be drawn in like manner; they will intersect each other in a number of points, the centre of which may be adopted as the most probable position of P. The co-ordinates of P will then be readily obtained from those of $p\pm$the distances on the meridian and perpendicular. In the annexed diagram (fig. 6) P is supposed to have been observed from five stations, giving as many intersecting rays, (1, 1), (2, 2), . . . ; there are ten points of intersection, the mean position of which gives the true position of P, the assumed position being p. The advantages claimed for the method are that, the bearings being independent, an erroneous bearing may be redrawn without disturbing those that are correct; similarly new bearings may be introduced without disturbing previous work, and observations from a large number of stations may be readily utilized, whereas, when calculation is resorted to, observations in excess of the minimum number required are frequently rejected because of the labour of computing them.

6. NAUTICAL SURVEYING

The great majority of nautical surveys are carried out by H.M. surveying vessels under the orders of the hydrographer of the admiralty. Plans of harbours and anchorages are also received from H.M. ships in commission on foreign stations, but surveys of an extended nature can hardly be executed except by a ship specially fitted and carrying a trained staff of officers. The introduction of steam placed means at the disposal of nautical surveyors which largely modified the conditions under which they had to work in the earlier days of sailing vessels, and it has enabled the ship to be used in various ways previously impracticable. The heavy draught of ships in the present day, the growing increase of ocean and coasting traffic all over the world, coupled with the desire to save distance by rounding points of land and other dangers as closely as possible, demand surveys on larger scales and in greater detail than was formerly necessary; and to meet these modern requirements resurveys of many parts of the world are continually being called for. Nautical surveys vary much in character according to the nature of the work, its importance to navigation, and the time available. The elaborate methods and rigid accuracy of a triangulation for geodetic purposes on shore are unnecessary,

[1] In the Indian survey, tables are employed for these calculations which give the value of 1″ of arc in feet on the meridian, and on each parallel of latitude, at intervals of 5′ apart; also a corresponding table of arc-versines (Pb) of spheroidal arcs of parallel (Bb) 1° in length, from which the arc-versines for shorter or longer arcs are obtained proportionally to the squares of the arcs; x is taken as the difference of longitude converted into linear measure.

and are not attempted; astronomical observations at intervals in an extended survey prevent any serious accumulation of errors consequent upon a triangulation which is usually carried out with instruments, of which an 8-in. theodolite is the largest size used, whilst 5-in. theodolites generally suffice, and the sextant is largely employed for the minor triangulation. The scales upon which nautical surveys are plotted range from ½ in. to 2 or 3 in. to the sea-mile in coast surveys for the ordinary purposes of navigation, according to the requirements; for detailed surveys of harbours or anchorages a scale of from 6 to 12 in. is usually adopted, but in special cases scales as large as 60 in. to the mile are used.

Instruments.

The following are the principal instruments required for use in the field: *Theodolite*, 5 in., fitted with large telescope of high power, with coloured shades to the eye-piece for observing the sun for true bearings. *Sextant*, 8 in. observing, stand and artificial horizon. *Chronometers*, eight box, and two or three pocket, are usually supplied to surveying vessels. *Sounding sextants*, differing from ordinary sextants in being lighter and handier. The arc is cut only to minutes, reading to large angles of as much as 140°, and fitted with a tube of bell shape so as to include a large field in the telescope, which is of high power. *Measuring chain* 100 ft. in length. *Ten-foot pole* for coast-lining, is a light pole carrying two oblong frames, 18 in. by 24 in., covered with canvas painted white, with a broad vertical black stripe in the centre and fixed on the pole 10 ft. apart. *Station-pointer*, an instrument in constant requisition either for sounding, coast-lining, or topographical plotting, which enables an observer's position to be fixed by taking two angles between three objects suitably situated. The movable legs being set to the observed angles, and placed on the plotting sheet, the chamfered edges of the three legs are brought to pass through the points observed. The centre of the instrument then indicates the observer's position. *Heliostats*, for reflecting the rays of the sun from distant stations to indicate their position, are invaluable. The most convenient form is Galton's sun signal; but an ordinary swing mirror, mounted to turn horizontally, will answer the purpose, the flash being directed from a hole in the centre of the mirror. *Pocket aneroid barometer*, required for topographical purposes. *Prismatic compass*, *patent logs* (taffrail and harpoon), *Lucas wire sounding machine* (large and small size), and *James's submarine sentry* are also required. For chart-room use are provided a graduated brass scale, steel straight-edges and beam compasses of different lengths, rectangular vulcanite or ivory protractors of 6-in. and 12-in. length, and semicircular brass protractors of 10-in. radius, a box of good mathematical drawing instruments, lead weights, drawing boards and mounted paper.

Marks and Beacons.

Every survey must have fixed objects which are first plotted on the sheet, and technically known as "points." A keen eye is required for natural marks of all kinds, but these must often be supplemented by whitewash marks, cairns, tripods or bushes covered with white canvas or calico, and flags, white or black according to background. On low coasts, flagstaffs upwards of 80 ft. high must sometimes be erected in order to get the necessary range of vision, and thereby avoid the evil of small triangles, in working through which errors accumulate so rapidly. A barling spar 35 ft. in length, securely stayed and carrying as a topmast (with proper guys) a somewhat lighter spar, lengthened by a long bamboo, will give the required height. A *fixed beacon* can be erected in shallow water, 2 to 3 fathoms in depth, by constructing a tripod of spars about 45 ft. long. The heads of two of them are lashed together, and the heels kept open at a fixed distance by a plank about 27 ft. long, nailed on at about 5 ft. above the heels of the spars. These are taken out by three boats, and the third tripod leg lashed in position on the boats, the heel in the opposite direction to the other two. The first two legs, weighted, are let go together; using the third leg as a prop, the tripod is hauled into position and secured by guys to anchors, and by additional weights slipped down the legs. A vertical pole with bamboo can now be added, its weighted heel being on the ground and lashed to the fork. On this a flag 14 ft. square may be hoisted. *Floating beacons* can be made by filling up flush the heads of two 27-gallon casks, connected by nailing a piece of thick plank at top and bottom. A barling spar passing through holes cut in the planks between the casks, projecting at least 20 ft. below and about 10 ft. above them, is toggled securely by iron pins above the upper and below the lower plank. To the upper part of the spar is lashed a bamboo, 30 to 35 ft. long, carrying a black flag 12 to 16 ft. square, which will be visible from the ship 10 m. in clear weather. The ends of a span of ½-in. chain are secured round the spar above and below the casks with a long link travelling upon it, to which the cable is attached by a slip, the end being carried up and lightly stopped to the bamboo below the flag. A wire strop, kept open by its own stiffness, is fitted to the casks for convenience in slipping and picking up. The beacon is moored with chain and rope half as long again as the depth of water. Beacons have been moored by sounding line in as great depth as 3000 fathoms with a weight of 100 lb.

"Fixing."

There is nothing in a nautical survey which requires more attention than the "fix"; a knowledge of the principles involved is essential in order to select properly situated objects. The method of fixing by two angles between three fixed points is generally known as the "two-circle method," but there are really three circles involved. The "station-pointer" is the instrument used for plotting fixes. Its contruction depends upon the fact that angles subtended by the chord of a segment of a circle measured from any point in its circumference are equal. The lines joining three fixed points form the chords of segments of three circles, each of which passes through the observer's position and two of the fixed points. The more rectangular the angle at which the circles intersect each other, and the more sensitive they are, the better will be the fix; one condition is useless without the other. A circle is "sensitive" when the angle between the two objects responds readily to any small movement of the observer towards or away from the centre of the circle passing through the observer's position and the objects. This is most markedly the case when one object is very close to the observer and the other very distant, but not so when *both* objects are distant. Speaking generally, the sensibility of angles depends upon the relative distance of the two objects from the observer, as well as the absolute distance of the nearer of the two. In the accompanying diagram A, B, C are the objects, and X the observer. Fig. 7 shows the circle passing through C, B and X, cutting the circle ABX at a good angle, and therefore fixing X independently of the circle CAX, which is less sensitive than either of the other two. In fig. 8 the two first circles are very sensitive, but being nearly tangential

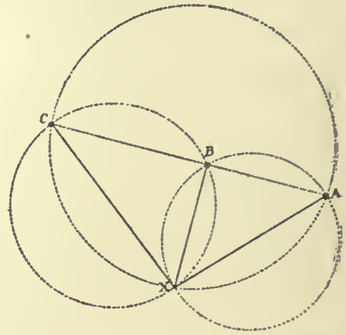

FIG. 7.

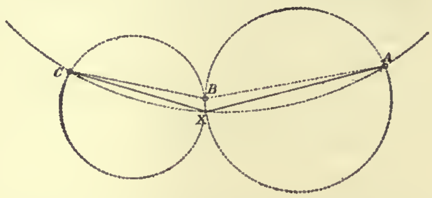

FIG. 8.

they give no cut with each other. The third circle cuts both at right angles; it is, however, far less sensitive, and for that reason if the right and left hand objects are both distant the fix must be bad. In such a case as this, because the angles CXB, BXA are both so sensitive, and the accuracy of the fix depends on the precision with which the angle CXA is measured, that angle should be observed direct, together with one of the other angles composing it. Fig. 9 represents a case where the points are badly disposed, approaching the condition known as "on the circle," passing through the three points. All three circles cut one another at such a fine angle as to give a very poor fix. The centre of the station-pointer could be moved considerably without materially affecting the coincidence of the legs with the three points. To avoid a bad fix the following rules are safe:—

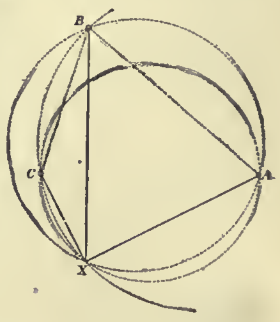

FIG. 9.

1. Never observe objects of which the central is the furthest unless it is *very* distant relatively to the other two, in which case the fix is admissible, but must be used with caution.

2. Choose objects disposed as follows: (*a*) One outside object distant and the other two near, the angle between the two near

objects being not less than 30° or more than 140°. The amount of the angle between the middle and distant object is immaterial. (*b*) The three objects nearly in a straight line, the angle between any two being not less than 30°. (*c*) The observer's position being inside the triangle formed by the objects.

A fix on the line of two points in transit, with an angle to a third point, becomes more sensitive as the distance between the transit points increases relatively to the distance between the front transit point and the observer; the more nearly the angle to the third point approaches a right angle, and the nearer it is situated to the observer, the better the fix. If the third point is at a long distance, small errors either of observation or plotting affect the result largely. A good practical test for a fix is afforded by noticing whether a very slight movement of the centre of the station-pointer will throw one or more of the points away from the leg. If it can be moved without appreciably disturbing the coincidence of the leg and all three points, the fix is bad.

Tracing-paper answers exactly the same purpose as the station-pointer. The angles are laid off from a centre representing the position, and the lines brought to pass through the points as before. This entails more time, and the angles are not so accurately measured with a small protractor. Nevertheless this has often to be used, as when points are close together on a small scale the central part of the station-pointer will often hide them and prevent the use of the instrument. The use of tracing-paper permits any number of angles to different points to be laid down on it, which under certain conditions of fixing is sometimes a great advantage.

Bases. Although marine surveys are in reality founded upon triangulation and measured bases of some description, yet when plotted irregularly the system of triangles is not always apparent. The triangulation ranges from the rough triangle of a running survey to the carefully formed triangles of detailed surveys. The measured base for an extended survey is provisional only, the scale resting ultimately mainly upon the astronomical positions observed at its extremes. In the case of a plan the base is absolute. The main triangulation, of which the first triangle contains the measured base as its known side, establishes a series of points known as main stations, from which and to which angles are taken to fix other stations. A sufficiency of secondary stations and marks enables the detail of the chart to be filled in between them. The points embracing the area to be worked on, having been plotted, are transferred to field boards, upon which the detail of the work in the field is plotted; when complete the work is traced and re-transferred to the plotting-sheet, which is then inked in as the finished chart, and if of large extent it is graduated on the gnomonic projection on the astronomical positions of two points situated near opposite corners of the chart.

The kind of base ordinarily used is one measured by chain on flat ground, of ½ to 1½ m. in length, between two points visible from one another, and so situated that a triangulation can be readily extended from them to embrace other points in the survey forming well-conditioned triangles. The error of the chain is noted before leaving the ship, and again on returning, by comparing its length with the standard length of 100 ft. marked on the ship's deck. The correction so found is applied to obtain the final result. If by reason of water intervening between the base stations it is impossible to measure the direct distance between them, it is permissible to deduce it by traversing.

A Masthead Angle Base is useful for small plans of harbours, &c., when circumstances do not permit of a base being measured on shore. The ship at anchor nearly midway between two base stations is the most favourable condition for employing this method. Theodolite reading of the masthead with its elevation by sextant observed simultaneously at each base station (the mean of several observations being employed) give the necessary data to calculate the distance between the base stations from the two distances resulting from the elevation of the masthead and the simultaneous theodolite-angles between the masthead and the base stations. The height of the masthead may be temporarily increased by securing a spar to extend 30 ft. or so above it, and the exact height from truck to netting is found by tricing up the end of the measuring chain. The angle of elevation should not be diminished below about 1° from either station.

Base by Sound.—The interval in seconds between the flash and report of a gun, carefully noted by counting the beats of a watch or pocket chronometer, multiplied by the rate per second at which sound travels (corrected for temperature) supplies a means of obtaining a base which is sometimes of great use when other methods are not available. Three miles is a suitable distance for such a base, and guns or small brass Cohorn mortars are fired alternately from either end, and repeated several times. The arithmetical mean is not strictly correct, owing to the retardation of the sound against the wind exceeding the acceleration when travelling with it; the formula used is therefore $T = \frac{2tt'}{t+t'}$ where T is the mean interval required, t the interval observed one way, t' the interval the other way. The method is not a very accurate one, but is sufficiently so when the scale is finally determined by astronomical observations, or for sketch surveys. The measurement should be across the wind if possible, especially if guns can only be fired from one end of the base. Sound travels about 1090 ft. per second at a temperature of 32° F., and increases at the rate of 1·15 ft. for each degree above that temperature, decreasing in the same proportion for temperatures below 32°.

Base by Angle of Short Measured Length.—An angle measured by sextant between two well-defined marks at a carefully measured distance apart, placed at right angles to the required base, will give a base for a small plan.

Astronomical Base.—The difference of latitude between two stations visible from each other and nearly in the same meridian, combined with their true bearings, gives an excellent base for an extended triangulation; the only drawback to it is the effect of local attraction of masses of land in the vicinity on the pendulum, or, in other words, on the mercury in the artificial horizon. The base stations should be as far apart as possible, in order to minimize the effect of any error in the astronomical observations. The observation spots would not necessarily be actually at the base stations, which would probably be situated on summits at some little distance in order to command distant views. In such cases each observation spot would be connected with its corresponding base station by a subsidiary triangulation, a short base being measured for the purpose. The ship at anchor off the observation spot frequently affords a convenient means of effecting the connexion by a masthead angle base and simultaneous angles. If possible, the observation spots should be east or west of the mountain stations from which the true bearings are observed.

If the base stations A and B are so situated that by reason of distance or of high land intervening they are invisible from one another, but both visible from some main station C between them, when the main triangulation is completed, the ratio of the sides AC, BC can be determined. From this ratio and the observed angle ACB, the angles ABC, BAC can be found. The true bearing of the lines AC or BC being known, the true bearing of the base stations A and B can be deduced.

Extension of Base.—A base of any description is seldom long enough to plot from directly, and in order to diminish errors of plotting it is necessary to begin on the longest side possible so as to work *inwards*. A short base measured on flat ground will give a better result than a longer one measured over inequalities, provided that the triangulation is carefully extended by means of judiciously selected triangles, great care being taken to plumb the centre of each station. To facilitate the extension of the base in as few triangles as possible, the base should be placed so that there are two stations, one on each side of it, subtending angles at them of from 30° to 40°, and the distances between which, on being calculated in the triangles of the quadrilateral so formed, will constitute the first extension of the base. Similarly, two other stations placed one on each side of the last two will form another quadrilateral, giving a yet longer side, and so on.

Main Triangulation. The angles to be used in the main triangulation scheme must be very carefully observed and the theodolite placed exactly over the centre of the station. Main angles are usually repeated several times by resetting the vernier at intervals equidistant along the arc, in order to eliminate instrumental errors as well as errors of observation. The selection of an object suitable for a zero is important. It should, if possible, be another main station at some distance, but not so far or so high as to be easily obscured, well defined, and likely to be permanent. Angles to secondary stations and other marks need not be repeated so many times as the more important angles, but it is well to check all angles once at least. Rough sketches from all stations are of great assistance in identifying objects from different points of view, the angles being entered against each in the sketch.

False Station.—When the theodolite cannot for any reason be placed over the centre of a station, if the distance be measured and the theodolite reading of it be noted, the observed angles may be reduced to what they would be at the centre of the station. False stations have frequently to be made in practice; a simple rule to meet all cases is of great assistance to avoid the possibility of error in applying the correction with its proper sign. This may very easily be found as follows, without having to bestow a moment's thought beyond applying the rule, which is a matter of no small gain in time when a large number of angles have to be corrected.

Rule.—Put down the theodolite reading which it is required to correct (increased if necessary by 360°), and from it subtract the theodolite reading of the centre of the station. Call this remainder θ. With θ as a "course" and the number of feet from the theodolite to the station as a "distance," enter the traverse table and take out the greater increment if θ lies between 45° and 135°, or between 225° and 315°, and the lesser increment for other angles. The accompanying diagram (fig. 10) will assist the memory. Refer this increment to the "table of subtended angles by various lengths at different distances" (using the distance of the object observed) and find the corresponding correction in arc, which mark + or − according as θ is under or over 180°. Apply this correction to the observed theodolite angle. A "table of subtended angles" is unnecessary if the formula

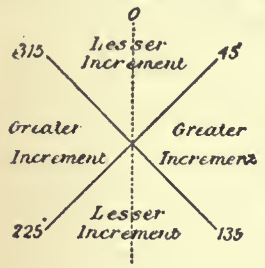

Fig. 10.

$$\text{Angle in seconds} = \frac{\text{number of feet subtended} \times 34}{\text{distance of object in sea-miles}}$$ be used instead.

Convergency of Meridians.—The difference of the reciprocal true bearings between two stations is called the "convergency." The formula for calculating it is: Conv. in minutes = dist. in sea-miles × sin. Merc. bearing × tan. mid. lat. Whenever true bearings are used in triangulation, the effect of convergency must be considered and applied. In north latitudes the southerly bearing is the greater of the two, and in south latitudes the northerly bearing. The Mercatorial bearing between two stations is the mean of their reciprocal true bearings.

Triangulated Coast Survey.

After a preliminary run over the ground to note suitable positions for main and secondary stations on prominent headlands, islands and summits not too far back from the coast, and, if no former survey exists, to make at the same time a rough plot of them by compass and patent log, a scheme must be formed for the main triangulation with the object of enclosing the whole survey in as few triangles as possible, regard being paid to the limit of vision of each station due to its height, to the existing meteorological conditions, to the limitations imposed by higher land intervening, and to its accessibility. The triangles decided upon should be well-conditioned, taking care not to introduce an angle of less than 30° to 35°, which is only permissible when the two longer sides of such a triangle are of nearly equal length, and when in the calculation that will follow one of these sides shall be derived from the other and not from the short side. In open country the selection of stations is comparatively an easy matter, but in country densely wooded the time occupied by a triangulation is mainly governed by the judicious selection of stations quickly reached, sufficiently elevated to command distant views, and situated on summits capable of being readily cleared of trees in the required direction, an all-round view being, of course, desirable but not always attainable. The positions of secondary stations will also generally be decided upon during the preliminary reconnaissance. The object of these stations is to break up the large primary triangles into triangles of smaller size, dividing up the distances between the primary stations into suitable lengths; they are selected with a view to greater accessibility than the latter, and should therefore usually be near the coast and at no great elevation. Upon shots from these will depend the position of the greater number of the coast-line marks, to be erected and fixed as the detailed survey of each section of the coast is taken in hand in regular order. The nature of the base to be used, and its position in order to fulfil the conditions specified under the head of *Bases* must be considered, the base when extended forming a side of one of the main triangles. It is immaterial at what part of the survey the base is situated, but if it is near one end, a satisfactory check on the accuracy of the triangulation is obtained by comparing the length of a side at the other extreme of the survey, derived by calculation through the whole system of triangles, with its length deduced from a check base measured in its vicinity. It is generally a saving of time to measure the base at some anchorage or harbour that requires a large scale plan. The triangulation involved in extending the base to connect it with the main triangulation scheme can thus be utilized for both purposes, and while the triangulation is being calculated and plotted the survey of the plan can be proceeded with. True bearings are observed at both ends of the survey and the results subsequently compared. Astronomical observations for latitude are obtained at observation spots near the extremes of the survey and the meridian distance run between them, the observation spots being connected with the primary triangulation; they are usually disposed at intervals of from 100 to 150 m., and thus errors due to a triangulation carried out with theodolites of moderate diameter do not accumulate to any serious extent. If the survey is greatly extended, intermediate observation spots afford a satisfactory check, by comparing the positions as calculated in the triangulation with those obtained by direct observation.

Calculating the Triangulation.—The triangles as observed being tabulated, the angles of each triangle are corrected to bring their sum to exactly 180°. We must expect to find errors in the triangles of as much as one minute, but under favourable conditions they may be much less. In distributing the errors we must consider the general skill of the observer, the size of his theodolite relatively to the others, and the conditions under which his angles were observed; failing any particular reason to assign a larger error to one angle than to another, the error must be divided equally, bearing in mind that an alteration in the small angle will make more difference in the resulting position than in either of the other two, and as it approaches 30° (the limit of a receiving angle) it is well to change it but very slightly in the absence of any strong reason to the contrary. The length of base being determined, the sides of all the triangles involved are calculated by the ordinary rules of trigonometry. Starting from the true bearing observed at one end of the survey, the bearing of the side of each triangle that forms the immediate line of junction from one to the other is found by applying the angles necessary for the purpose in the respective triangles, not forgetting to apply the convergency between each pair of stations when reversing the bearings. The bearing of the final side is then compared with the bearing obtained by direct observation at that end of the survey. The difference is principally due to accumulated errors in the triangulation; half of the difference is then applied to the bearing of each side. Convert these true bearings into Mercatorial bearings by applying half the convergency between each pair of stations. With the lengths of the connecting sides found from the measured base and their Mercatorial bearing, the Mercatorial bearing of one observation spot from the other is found by middle latitude sailing. Taking the observed astronomical positions of the observation spots and first reducing their true difference longitude to departure, as measured on a spheroid from the formula Dep. = T. D. long. $\frac{\text{no. ft. in 1 m. of long.}}{\text{no. ft. in 1 m. of lat.}}$, then with the d. lat. and dep. the Mercatorial true bearing and distance between the observation spots is calculated by middle latitude sailing, and compared with that by triangulation and measured base. To adjust any discrepancy, it is necessary to consider the probable error of the observations for latitude and meridian distance; within those limits the astronomical positions may safely be altered in order to harmonize the results; it is more important to bring the bearings into close agreement than the distance. From the amended astronomical positions the Mercatorial true bearings and distance between them are re-calculated. The difference between this Mercatorial bearing and that found from the triangulation and measured base must be applied to the bearing of each side to get the final corrected bearings, and to the logarithm of each side of the triangulation as originally calculated must be added or subtracted the difference between the logarithms of the distance of the amended positions of the observation spots and the same distance by triangulation.

Calculating Intermediate Astronomical Positions.—The latitude and longitude of any intermediate main station may now be calculated from the finally corrected Mercatorial true bearings and lengths of sides. The difference longitude so found is what it would be if measured on a true sphere, whereas we require it as measured on a spheroid, which is slightly less. The correction = d. long. $\frac{\cos^2 \text{mid. lat.}}{150}$ must therefore be subtracted; or the true difference longitude may be found direct from the formula dep. $\frac{\text{no. ft. in 1 m. of lat.}}{\text{no. ft. in 1 m. of long.}}$. From the foregoing it is seen that in a triangulation for hydrographical purposes both the bearings of the sides and their lengths ultimately depend almost entirely upon the astronomical observations at the extremes of the survey; the observed true bearings and measured base are consequently more in the nature of checks than anything else. It is obvious, therefore, that the nearer together the observation spots, the greater effect will a given error in the astronomical positions have upon the length and direction of the sides of the triangulation, and in such cases the bearings as actually observed must not be altered to any large extent when a trifling change in the astronomical positions might perhaps effect the required harmony. For the reasons given under *Astronomical Base*, high land near observation spots may cause very false results, which may often account for discrepancies when situated on opposite sides of a mountainous country.

Plotting.

Great care is requisite in projecting on paper the points of a survey. The paper should be allowed to stretch and shrink as it pleases until it comes to a stand, being exposed to the air for four or five hours daily, and finally well flattened out by being placed on a table with drawing boards placed over it heavily weighted. If the triangulation has been calculated beforehand throughout, and the lengths of all the different sides have been found, it is more advantageous to begin plotting by distances rather than by chords. The main stations are thus got down in less time and with less trouble, but these are only a small proportion of the points to be plotted, and long lines must be ruled between the stations as zeros for plotting other points by chords. In ruling these lines care must be taken to draw them exactly through the centre of the pricks denoting the stations, but, however carefully drawn, there is liability to slight error in any line projected to a point lying beyond the distance of the stations between which the zero line is drawn. In plotting by distances, therefore, all points that will subsequently have to be plotted by chords should lie well within the area covered by the main triangulation. Three distances must be measured to obtain an intersection of the arcs cutting each other at a sufficiently broad angle; the plotting of the main stations once begun must be completed before distortion of the paper can occur from change in the humidity of the atmosphere. Plotting, whether by distance or by chords, must be begun on as long a side as possible, so as to plot *inwards*, or with decreasing distances. In plotting by chords it is important to remember in the selection of lines of reference (or zero lines), that that should be preferred which makes the smallest angle with the line to be projected from it, and of the angular points those nearest to the object to be projected from them.

Irregular Methods of Plotting.—In surveys for the ordinary purposes of navigation, it frequently happens that a regular system of triangulation cannot be carried out, and recourse must be had to a variety of devices; the judicious use of the ship in such cases is often essential, and with proper care excellent results may be obtained. A few examples will best illustrate some of the methods used, but circumstances vary so much in every survey that it is only possible to meet them properly by studying each case as it arises, and to improvise methods. Fixing a position by means of the "back-angle" is one of the most ordinary expedients. Angles having been observed at A, to the station B, and certain other fixed points of the survey, C and D for instance; if A is shot up from B, at which station angles to the same fixed points have been observed, then it is not necessary to visit those points to fix A. For instance, in the triangle ABC, two of the angles have been observed, and therefore the third angle at C is known (the three angles of a triangle being equal to 180°), and it is called the "calculated or back-angle from C." A necessary condition is that the receiving angle at A, between any two lines (direct or calculated), must be sufficiently broad to give a good cut; also the points from which the "back-angles" are calculated should not be situated at too great distances from A, relatively to the distance between A and B. A station may be plotted by laying down the line to it from some other station, and then placing on tracing-paper a number of the angles taken at it, including the angle to the station from which it has been shot up. If the points to which angles are taken are well situated, a good position is obtained, its accuracy being much strengthened by being able to plot on a line to it, which, moreover, forms a good zero line for laying off other angles from the station when plotted. Sometimes the main stations must be carried on with a point plotted by only two angles. An effort must be made to check this subsequently by getting an "angle back" from stations dependent upon it to some old well-fixed point; failing this, two stations being plotted with two angles, pricking one and laying down the line to the other will afford a check. A well-defined mountain peak, far inland and never visited, when once it is well fixed is often invaluable in carrying on an irregular triangulation, as it may remain visible when all other original points of the survey have disappeared, and "back-angles" from it may be continually obtained, or it may be used for plotting on true bearing lines of it. In plotting the true bearing of such a peak, the convergency must be found and applied to get the reversed bearing, which is then laid down from a meridian drawn through it; or the reversed bearing of any other line already drawn through the peak being known, it may simply be laid down with that as a zero. A rough position of the spot from which the true bearing was taken must be assumed in order to calculate the convergency. Fig. 11 will illustrate the foregoing remarks. A and B are astronomical observation spots at the extremes of a survey, from both of which the high, inaccessible peak C is visible. D, E, F are intermediate stations; A and D, D and E, E and F, F and B being respectively visible from each other. G is visible from A and D, and C is visible from all stations. The latitudes of A and B and meridian distance between them being determined, and the true bearing of C being observed from both observation spots, angles are observed at all the stations. Calculating the spheroidal correction (from the formula, correction $= \text{d. long.}\ \dfrac{\cos^2 \text{mid. lat.}}{150}$) and adding it to the true (or chronometric) difference longitude between A and B to obtain the spherical d. long.; with this spherical d. long. and the d. lat., the Mercatorial true bearing and distance is found by middle latitude sailing (which is an equally correct but shorter method than by spherical trigonometry, and may be safely used when dealing with the distances usual between observation spots in nautical surveys). The convergency is also calculated, and the true bearing of A from B and B from A are thus determined. In the plane triangle ABC the angle A is the difference between the calculated bearing of B and the observed bearing of C from A; similarly angle B is the difference between calculated bearing of A and observed bearing of C from B. The distance AB having been also calculated, the side AC is found. Laying down AC on the paper on the required scale, D is plotted on its direct shot from A, and on the angle back from C, calculated in the triangle ACD. G is plotted on the direct shots from A and D, and on the angle back from C, calculated either in the triangle ACG or GCD. The perfect intersection of the three lines at G assures these four points being correct. E, F and B are plotted in a similar manner. The points are now all plotted, but they depend on calculated angles, and except for the first four points we have no check whatever either on the accuracy of the angles observed in the field or on the plotting. Another well-defined object in such a position, for instance as Z, visible from three or more stations, would afford the necessary check, if lines laid off to it from as many stations as possible gave a good intersection. If no such point, however, exists, a certain degree of check on the angles observed is derived by applying the sum of all the calculated angles at C to the true bearing of A from C (found by reversing observed bearing of C from A with convergency applied), which will give the bearing of B from C. Reverse this bearing with convergency applied, and compare it with the observed bearing of C from B. If the discrepancy is but small, it will be a strong presumption in favour of the substantial accuracy of the work. If the calculated true bearing of B from A be now laid down, it is very unlikely that the line will pass through B, but this is due to the discrepancy which must always be expected between astronomical positions and triangulation. If some of the stations between A and B require to be placed somewhat closely to one another, it may be desirable to obtain fresh true bearings of C instead of carrying on the original bearing by means of the calculated angle.

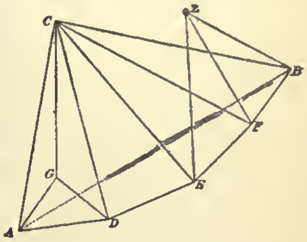

Fig. 11.

In all cases of irregular plotting the ship is very useful, especially if she is moored taut without the swivel, and angles are observed from the bow. Floating beacons may also assist an irregular triangulation.

Sketch Surveys.

Surveys of various degrees of accuracy are included among sketch surveys. The roughest description is the ordinary running survey, when the work is done by the ship steaming along the coast, fixing points, and sketching in the coast-line by bearings and angles, relying for her position upon her courses and distances as registered by patent log, necessarily regardless of the effect of wind and current and errors of steerage. At the other extreme comes the modified running survey, which in point of practical accuracy falls little short of that attained by irregular triangulation. Some of these modifications will be briefly noticed. A running survey of a coast-line between two harbours, that have been surveyed independently and astronomically fixed, may often be carried out by fixing the ship on the points already laid down on the harbour surveys and shooting up prominent intermediate natural objects, assisted possibly by theodolite lines from the shore stations. Theodolite lines to the ship at any of her positions are particularly valuable, and floating beacons suitably placed materially increase the value of any such work. A sketch survey of a coast upon which it is impossible to land may be well carried out by dropping beacons at intervals of about 10 m., well out from the land and placed abreast prominent natural objects called the "breastmarks," which must be capable of recognition from the beacons anchored off the next "breastmark" on either side. The distance between the beacons is found by running a patent log both ways, noting the time occupied by each run; if the current has remained constant, a tolerably good result can be obtained. At the first beacon, angles are observed between the second beacon and the two "breastmarks," an "intermediate" mark, and any other natural object which will serve as "points." At the second beacon, angles are observed between the first beacon and the same objects as before. Plotting on the line of the two beacons as a base, all the points observed can be pricked in on two shots. At a position about midway between the beacons, simultaneous angles are observed to all the points and laid off on tracing-paper, which will afford the necessary check, and the foundation is thus laid for filling in the detail of coast-line, topography, and soundings off this particular stretch of coast in any detail desired. Each section of coast is complete in itself on its own base; the weak point lies in the junction of the different sections, as the patent log bases can hardly be expected to agree precisely, and the scales of adjacent sections may thus be slightly different. This is obviated, as far as possible, by fixing on the points of one section and shooting up those of another, which will check any great irregularity of scale creeping in. The bearing is preserved by getting occasional true bearing lines at the beacons of the most distant point visible. Space does not here permit of dwelling upon the details of the various precautions that are necessary to secure the best results the method is capable of; it can only be stated generally that in all cases of using angles from the ship under weigh, several assistants are necessary, so that the principal angles may be taken simultaneously, the remainder being connected immediately afterwards with zeros involving the smallest possible error due to the ship not being absolutely stationary, these zeros being included amongst the primary angles. When close to a beacon, if its bearing is noted and the distance in feet obtained from its elevation, the angles are readily reduced to the beacon itself. Astronomical positions by twilight stars keep a check upon the work.

Sketch Surveys by Compass Bearings and Vertical Angles.—In the case of an island culminating in a high, well-defined summit visible from all directions, a useful and accurate method is to steam round it at a sufficient distance to obtain a true horizon, stopping to make as many stations as may be desirable, and fixing by compass bearing of the summit and its vertical angle. The height is roughly obtained by shooting in the summit, from two positions on a patent log base whilst approaching it. With this approximate height and Lecky's vertical danger angle tables, each station may be plotted on its bearing of the summit. From these stations the island is shot in by angles between its tangents and the summit, and angles to any other natural features, plotting the work as we go on any convenient scale which must be considered only as provisional. On completing the circuit of the island, the true scale is found by measuring the total distance in inches on the plotting-sheet from the first to the last station, and dividing it by the distance in miles between them as shown by patent log. The final height of the summit bears to the rough height used in plotting the direct proportion of the provisional scale to the true scale. This method may be utilized for the sketch survey of a coast where there are well-defined peaks of sufficient height at convenient intervals, and would be superior to an ordinary running survey. From positions of the ship fixed by bearings and elevations of one peak, another farther along the coast is shot in and its height determined; this second peak is then used in its turn to fix a third, and so on. The smaller the vertical angle the more liability there is to error, but a glance at Lecky's tables will show what effect an error of say 1′ in altitude will produce for any given height and distance, and the limits of distance must depend upon this consideration.

Surveys of Banks out of Sight of Land.—On striking shoal soundings unexpectedly, the ship may either be anchored at once and the shoal sounded by boats starring round her, using prismatic compass and masthead angle; or if the shoal is of large extent and may be prudently crossed in the ship, it is a good plan to get two beacons laid down on a bearing from one another and patent log distance of 4 or 5 m. With another beacon (or mark-boat, carrying a large black flag on a bamboo 30 ft. high) fixed on this base, forming an equilateral triangle, and the ship anchored as a fourth point, soundings may be carried out by the boats fixing by station-pointer. The ship's position is determined by observations of twilight stars.

Coast-lining. In a detailed survey the coast is sketched in by walking along it, fixing by theodolite or sextant angles, and plotting by tracing-paper or station-pointer. A sufficient number of fixed marks along the shore afford a constant check on the minor coast-line stations, which should be plotted on, or checked by, lines from one to the other wherever possible to do so. When impracticable to fix in the ordinary way, the ten-foot pole may be used to traverse from one fixed point to another. With a coast fronted by broad drying, coral reef or flats over which it is possible to walk, the distance between any two coast-line stations may be found by measuring at one of them the angle subtended by a known length placed at right angles to the line joining the stations. There is far less liability to error if the work is plotted at once on the spot on field board with the fixed points pricked through and circled in upon it; but if circumstances render it necessary, the angles being registered and sketches made of the bits of coast between the fixes on a scale larger than that of the chart, they may be plotted afterwards; to do this satisfactorily, however, requires the surveyor to appreciate instinctively exactly what angles are necessary at the time. It is with the high-water line that the coast-liner is concerned, delineating its character according to the admiralty symbols. The officer sounding off the coast is responsible for the position of the dry line at low-water, and on large scales this would be sketched in from a small boat at low-water springs. Heights of cliffs, rocks, islets, &c., must be inserted, either from measurement or from the formula,

$$\text{height in feet} = \frac{\text{angle of elevation in seconds} \times \text{distance in miles,}}{34}$$

and details of topography close to the coast, including roads, houses and enclosures, must be shown by the coast-liner. Rocks above water or breaking should be fixed on passing them. Coast-line may be sketched from a boat pulling along the shore, fixing and shooting up any natural objects on the beach from positions at anchor.

Sounding. The most important feature of a chart is the completeness with which it is sounded. Small scale surveys on anything less than one inch to the mile are apt to be very misleading; such a survey may appear to have been closely sounded, but in reality the lines are so far apart that they often fail to disclose indications of shoal-water. The work of sounding may be proceeded with as soon as sufficient points for fixing are plotted; but off an intricate coast it is better to get the coast-line done first. The lines of soundings are run by the boats parallel to one another and perpendicular to the coast at a distance apart which is governed by the scale; five lines to the inch is about as close as they can be run without overcrowding; if closer lines are required the scale must generally be increased. The distance apart will vary with the depth of water and the nature of the coast; a rocky coast with shallow water off it and projecting points will need much closer examination than a steep-to coast, for instance. The line of prolongation of a point under water will require special care to ensure the fathom lines being drawn correctly. If the soundings begin to decrease when pulling off-shore it is evidence of something suspicious, and intermediate lines of soundings or lines at right angles to those previously run should be obtained. Whenever possible lines of soundings should be run on transit lines; these may often be picked up by fixing when on the required line, noting the angle on the protractor between the line and some fixed mark on the field board, and then placing the angle on the sextant, reflecting the mark and noting what objects are in line at that angle. On large scale surveys whitewash marks or flags should mark the ends of the lines, and for the back transit marks natural objects may perhaps be picked up; if not, they must be placed in the required positions. The boat is fixed by two angles, with an occasional third angle as a check; the distance between the fixes is dependent upon the scale of the chart and the rapidity with which the depth alters; the 3, 5 and 10 fathom lines should always be fixed, allowing roughly for the tidal reduction. The nature of the bottom must be taken every few casts and recorded. It is best to plot each fix on the sounding board at once, joining the fixes by straight lines and numbering them for identification. The tidal reduction being obtained, the reduced soundings are written in the field-book in red underneath each sounding as originally noted; they are then placed in their proper position on the board between the fixes. Suspicious ground should be closely examined; a small nun buoy anchored on the shoal is useful to guide the boat while trying for the least depth. Sweeping for a reported pinnacle rock may be resorted to when sounding fails to discover it. Local information from fishermen and others is often most valuable as to the existence of dangers. Up to depths of about 15 fathoms the hand lead-line is used from the boats, but beyond that depth the small Lucas machine for wire effects a great saving of time and labour. The deeper soundings of a survey are usually obtained from the ship, but steamboats with wire sounding machines may assist very materially. By the aid of a steam winch, which by means of an endless rounding line hauls a 100-lb lead forward to the end of the lower boom rigged out, from which it is dropped by a slipping apparatus which acts on striking the water, soundings of 40 fathoms may be picked up from the sounding platform aft, whilst going at a speed of $4\frac{1}{2}$ knots. In deeper water it is quicker to stop the ship and sound from aft with the wire sounding machine. In running long lines of soundings on and off shore, it is very essential to be able to fix as far from the land as possible. Angles will be taken from aloft for this purpose, and a few floating beacons dropped in judiciously chosen positions will often well repay the trouble. A single fixed point on the land used in conjunction with two beacons suitably placed will give an admirable fix. A line to the ship or her smoke from one or two theodolite stations on shore is often invaluable; if watches are compared, observations may be made at stated times and plotted afterwards. True bearings of a distant fixed object cutting the line of position derived from an altitude of the sun is another means of fixing a position, and after dark the true bearing of a light may be obtained by the time azimuth and angular distance of a star near the prime vertical, or by the angular distance of Polaris in the northern hemisphere.

Vigias. A very large percentage of the bugbears to navigation denoted by vigias[1] on the charts eventually turn out to have no existence, but before it is possible to expunge them a large area has to be examined. No-bottom soundings are but little use, but the evidence of positive soundings should be conclusive. Submarine banks rising from great depths necessarily stand on bases many square miles in area. Of recent years our knowledge of the angle of slope that may be expected to occur at different depths has been much extended. From depths of upwards of 2000 fathoms the slope is so gradual that a bank could hardly approach the surface in less than 7 m. from such a sounding; therefore anywhere within an area of at least 150 sq. m. all round a bank rising from these depths, a sounding must show some decided indications of a rise in the bottom. Under such circumstances, soundings at intervals of 7 m., and run in parallel lines 7 m. apart, enclosing areas of only 50 sq. m. between any four adjacent soundings, should effectually clear up the ground and lead to the discovery of any shoal; and in fact the soundings might even be more widely spaced. From depths of 1500 and 1000 fathoms, shoals can scarcely occur within $3\frac{1}{2}$ m. and 2 m. respectively; but as the depth decreases the angle of slope rapidly increases, and a shoal might occur within three-quarters of a mile or even half a mile of such a sounding as 500 fathoms. A full appreciation of these facts will indicate the distance apart at which it is proper to place soundings in squares suitable to the general depth of water. Contour lines will soon show in which direction to prosecute the search if any irregularity of depth is manifested. When once a decided indication is found, it is not difficult to follow it up by paying attention to the contour lines as developed by successive soundings. Discoloured water, ripplings, fish jumping or birds hovering about may assist in locating a shoal, but the submarine sentry towed at a depth of 40 fathoms is here invaluable, and may save hours of hunting. Reports being more liable to errors of longitude than of latitude, a greater margin is necessary in that direction. Long parallel lines east and west are preferable, but the necessity of turning the ship more or less head to wind at every sounding makes it desirable to run the lines with the wind abeam, which tends to disturb the dead reckoning least. A good idea of the current may be obtained from the general direction of the ship's head whilst sounding considered with reference to the strength and direction of the wind, and it should be allowed for in shaping the course to preserve the parallelism of the lines, but the less frequently the course is altered the better. A good position in the morning should be obtained by pairs of stars on opposite bearings, the lines of position of one pair cutting those of another pair nearly at right angles. The dead reckoning should be checked by lines of position from observations of the sun about every two hours throughout the day, preferably whilst a sounding is being obtained and the ship stationary. Evening twilight stars give another position.

[1] A Spanish word meaning "look-out," used of marks on the chart signifying obstructions to navigation.

Tides.—The datum for reduction of soundings is low-water ordinary springs, the level of which is referred to a permanent bench mark in order that future surveys may be reduced to the same datum level. Whilst sounding is going on the height of the water above this level is observed by a tide gauge. The time of high-water at full and change, called the "establishment," and the heights to which spring and neap tides respectively rise above the datum are also required. It is seldom that a sufficiently long series of observations can be obtained for their discussion by harmonic analysis, and therefore the graphical method is preferred; an abstract form provides for the projection of high and low waters, lunitidal intervals, moon's meridian passage, declination of sun and moon, apogee and perigee, and mean time of high-water following superior transit, and of the highest tide in the twenty-four hours. A good portable automatic tide gauge suitable for all requirements is much to be desired.

Tidal Streams and Surface Currents are observed from the ship or boats at anchor in different positions, by means of a current log; or the course of a buoy drifted by the current may be followed by a boat fixing at regular intervals. Tidal streams often run for some hours after high and low water by the shore; it is important to find out whether the change of stream occurs at a regular time of the tide. *Undercurrents* are of importance from a scientific point of view. A deep-sea current meter, devised (1876) by Lieut. Pillsbury, U.S.N., has, with several modifications, been used with success on many occasions, notably by the U.S. Coast and Geodetic Survey steamer "Blake" in the investigation of the Gulf Stream.

Deep-sea Current Meter. The instrument is first lowered to the required depth, and when ready is put into action by means of a heavy weight, or messenger, travelling down the supporting line and striking on a metal plate, thus closing the jaws of the levers and enabling the instrument to begin working. The rudder is then free to revolve inside the framework and take up the direction of the current; the small cones can revolve on their axis and register the number of revolutions, while the compass needle is released and free to take up the north and south line. On the despatch of a second messenger, which strikes on top of the first and fixes the jaws of the levers open, every part of the machine is simultaneously locked. Having noted the exact time of starting each of the messengers, the time during which the instrument has been working at the required depth is known, and from this the velocity of the current can be calculated, the number of revolutions having been recorded, while the direction is shown by the angle between the compass needle and the direction of the rudder.

The instrument is shown in fig. 12. AA are the jaws of the levers through which the first messenger passes and strikes on the metal plate B. The force of the blow is sufficient to press B down, thus bringing the jaws as close together as possible, and putting the meter into action. The second messenger falling on the first opens the levers again and prevents their closing, thus keeping all parts of the machine locked. C is the rudder which takes up the direction of the current when the levers are unlocked. D is a set of small levers on the rudder in connexion with AA. The outer end on the tail of the rudder fits into the notches on the outer ring of the frame when the machine is locked and thus keeps the rudder fixed, but when the first messenger has started the machine by pressing down B and opening the levers AA, this small lever is raised and the rudder can revolve freely. EE are four small cones which revolve on their axis in a vertical plane, similar to an anemometer; the axis is connected by a worm screw to geared wheels which register the number of revolutions up to 5000, corresponding to about 4 nautical miles. There is a small lever in connexion with AA which prevents the cones revolving when the machine is locked, but allows them to revolve freely when the machine is in action. Below the rudder-post is a compass-bowl F, which is hung in gimbals and capable of removal. The needle is so arranged that it can be lifted off the pivot by means of a lever in connexion with AA; when the meter is in action the needle swings freely on its pivot, but when the levers are

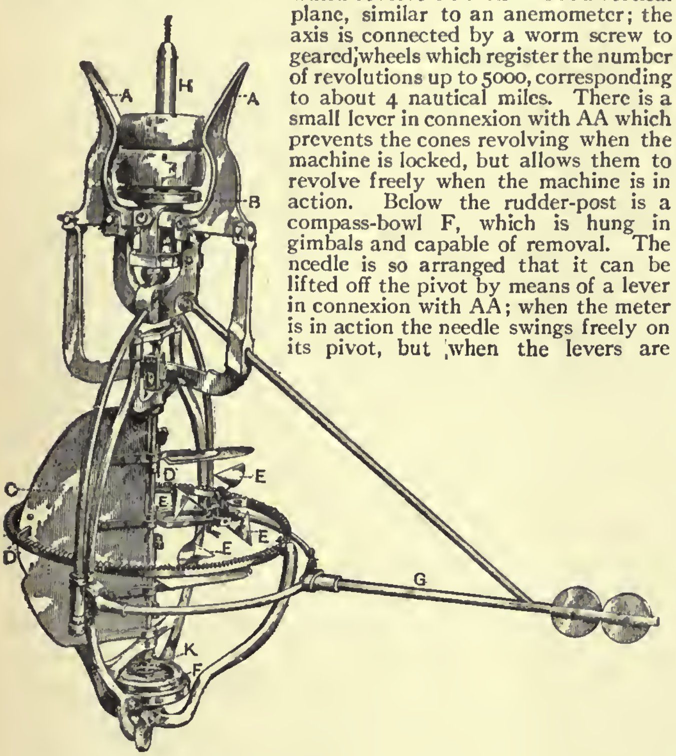

FIG. 12.

locked it is raised off its pivot by the inverted cup-piece K placed inside the triple claws on the top of the compass and screwed to the lever, thus locking the needle without chance of moving. The compass bowl should be filled with fresh water before lowering the instrument into the sea, and the top screwed home tightly. The needle should be removed and carefully dried after use, to prevent corrosion. The long arm G is to keep the machine steady in one direction; it works up and down a jackstay which passes between two sheaves at the extremity of the long arm. This also assists to keep the machine in as upright a position as possible, and prevents it from being drifted astern with the current. A weight of as much as 8 or 10 cwt. is required at the bottom of the jackstay in a very strong current. An elongated weight of from 60 to 80 lb must be suspended from the eye at the bottom of the meter to help to keep it as vertical as possible. On the outer part of the horizontal notched ring forming the frame, and placed on the side of the machine opposite to the projecting arm G, it has been found necessary to bolt a short arm supported by stays from above, from which is suspended a leaden counterpoise weight to assist in keeping the apparatus upright. This additional fitting is not shown in fig. 12. A $\frac{3}{4}$-in. phosphor-bronze wire rope is used for lowering the machine; it is rove through a metal sheave H and india-rubber washer, and spliced round a heart which is attached to metal plate B. The messengers are fitted with a hinged joint to enable them to be placed round the wire rope, and secured with a screw bolt. To obtain the exact value of a revolution of the small cones it is necessary to make experiments when the actual speed of the current is known, by immersing the meter just below the surface and taking careful observations of the surface-current by means of a current log or weighted pole. From the number of revolutions registered by the meter in a certain number of minutes, and taking the mean of several observations, a very fair value for a revolution can be deduced. On every occasion of using the meter for under-current observations the value of a revolution should be re-determined, as it is apt to vary owing to small differences in the friction caused by want of oil or the presence of dust or grit; while the force of the current is probably another important factor in influencing the number of revolutions recorded.

Topography. The features of the country should generally be delineated as far back as the skyline viewed from seaward, in order to assist the navigator to recognize the land. The summits of hills and conspicuous spurs are fixed either by lines to or by angles at them; their heights are determined by theodolite elevations or depressions to or from stations whose height above high-water is known. As much of the ground as possible is walked over, and its shape is delineated by contour lines sketched by eye, assisted by an aneroid barometer. In wooded country much of the topography may have to be shot in from the ship; sketches made from different positions at anchor along the coast with angles to all prominent features, valleys, ravines, spurs of hills, &c., will give a very fair idea of the general lie of the country.

Latitudes. Circum-meridian altitudes of stars on opposite sides of the zenith observed by sextant in the artificial horizon is the method adopted wherever possible for observations for latitudes. Arranged in pairs of nearly the same altitude north and south of zenith, the mean of each pair should give a result from which instrumental and personal errors and errors due to atmospheric conditions are altogether eliminated. The mean of several such pairs should have a probable error of not more than $\pm 1''$. As a rule the observations of each star should be confined to within 5 or 6 minutes on either side of the meridian, which will allow of from fifteen to twenty observations. Two stars selected to "pair" should pass the meridian within an hour of each other, and should not differ in altitude more than 2° or 3°. Artificial horizon roof error is eliminated by always keeping the same end of the roof towards the observer; when observing a single object, as the sun, the roof must be reversed when half way through the observations. The observations are reduced to the meridian by Raper's method. When pairs of stars are not observed, circum-meridian altitudes of the sun alone must be resorted to, but being observed on one side of the zenith only, none of the errors to which all observations are liable can be eliminated.

Chronometer Errors. Sets of equal altitudes of sun or stars by sextant and artificial horizon are usually employed to discover chronometer errors. Six sets of eleven observations, a.m. and p.m., observing both limbs of the sun, should give a result which, under favourable conditions of latitude and declination, might be expected to vary less than two-tenths of a second from the normal personal equation of the observer. Stars give equally good results. In high latitudes sextant observations diminish in value owing to the slower movement in altitude. In the case of the sun all the chronometers are compared with the "standard" at apparent noon; the comparisons with the chronometer used for the observations on each occasion of landing and returning to the ship are worked up to noon. In the case of stars, the chronometer comparisons on leaving and again on returning are worked up to an intermediate time. A convenient system, which retains the advantage of the equal altitude method, whilst avoiding the necessity of waiting some hours for the p.m. observation, is to observe two stars at equal altitudes on opposite sides of the meridian, and, combining the observations, treat them as relating to an imaginary star having the mean R.A. and mean declination of the two stars selected, which should have nearly the same declination and should differ from 4^h to 8^h in R.A.

Meridian Distances. The error of chronometer on mean time of place being obtained, the local time is transferred from one observation spot to another by the ship carrying usually eight box chronometers. The best results are found by using travelling rates, which are deduced from the difference of the errors found on leaving an observation spot and returning to it; from this difference is eliminated that portion which may have accumulated during an interval between two determinations of error at the other, or any intermediate, observation spot. A travelling rate may also be obtained from observations at two places, the meridian distance between which is known; this rate may then be used for the meridian distance between places observed at during the passage. Failing travelling rates, the mean of the harbour rates at either end must be used. The same observer, using the same instrument, must be employed throughout the observations of a meridian distance.

If the telegraph is available, it should of course be used. The error on local time at each end of the wire is obtained, and a number of telegraphic signals are exchanged between the observers, an equal number being transmitted and received at either end. The local time of sending a signal from one place being known and the local time of its reception being noted, the difference is the meridian distance. The retardation due to the time occupied by the current in travelling along the wire is eliminated by sending signals in both directions. The relative personal equation of the observers at either end, both in their observations for time, and also in receiving and transmitting signals, is eliminated by changing ends and repeating the operations. If this is impracticable, the personal equations should be determined and applied to the results. Chronometers keeping solar time at one end of the wire, and sidereal time at the other end, materially increase the accuracy with which signals can be exchanged, for the same reason that comparisons between sidereal clocks at an observatory are made through the medium of a solar clock. Time by means of the sextant can be so readily obtained, and within such small limits of error, by skilled observers, that in hydrographic surveys it is usually employed; but if transit instruments are available, and sufficient time can be devoted to erecting them properly, the value of the work is greatly enhanced in high latitudes.

True Bearings.

True bearings are obtained on shore by observing with theodolite the horizontal angle between the object selected as the zero and the sun, taking the latter in each quadrant as defined by the cross-wires of the telescope. The altitude may be read on the vertical arc of the theodolite; except in high latitudes, where a second observer with sextant and artificial horizon are necessary, unless the precise errors of the chronometers are known, when the time can be obtained by carrying a pocket chronometer to the station. The sun should be near the prime vertical and at a low altitude; the theodolite must be very carefully levelled, especially in the position with the telescope pointing towards the sun. To eliminate instrumental errors the observations should be repeated with the vernier set at intervals equidistant along the arc, and a.m. and p.m. observations should be taken at about equal altitudes.

At sea true bearings are obtained by measuring with a sextant the angle between the sun and some distant well-defined object making an angle of from 100° to 120° and observing the altitude of the sun at the same time, together with that of the terrestrial object. The sun's altitude should be low to get the best results, and both limbs should be observed. The sun's true bearing is calculated from its altitude, the latitude, and its declination; the horizontal angle is applied to obtain the true bearing of the zero. On shore the theodolite gives the horizontal angle direct, but with sextant observations it must be deduced from the angular distance and the elevation.

"SURVILLE, CLOTILDE DE," the supposed author of the *Poésies de Clotilde*. The generally accepted legend gave the following account of her. Marguerite Éléonore Clotilde de Vallon Challis, dame de Surville, was born in the early years of the 15th century at Vallon. In 1421 she married Bérenger de Surville, who was killed at the siege of Orleans in 1428. Her husband's absence at the war inspired her heroic verses and his death her elegiac poems. The last of her poems is a *chant royal* addressed to Charles VIII.

In 1803 Charles Vanderbourg published as the *Poésies de Clotilde* some forty poems dealing with love and war. The history given in the introduction of the discovery of the manuscript was evidently a fable, and the poems were set down by most authorities as forgeries, especially as they contained many anachronisms and were written in accordance with modern laws of prosody. The manuscript had been in the possession of Jean François Marie, marquis de Surville, an *émigré* who returned to France in 1798 to raise an insurrection in Provence, and had paid the penalty with his life. In 1863 Antonin Macé made further inquiries on the subject and discovered letters from Vanderbourg to Surville's widow. This correspondence makes it clear that Vanderbourg was innocent of forgery and believed that the poems were of 15th-century date, and that the anachronisms of matter and form were due to retouching by Surville. But the researches of M. Macé interested local antiquarians, and documentary evidence was produced that the wife of Bérenger de Surville was Marguerite Chalis, not Clotilde, and that the marriage dated only from 1428. Moreover Bérenger, whose death at the siege of Orleans was one of the leading motives of the book, lived for twenty years after that date. Friends of M. de Surville also disclosed the fact that the marquis had contributed archaic poetry to a Lausanne journal.

Mazon, *Marguerite Chalis et la légende de Clotilde de Surville* (1875); articles by Gaston Paris in the *Revue critique d'histoire et de littérature* (March 1, 1873 and May 30, 1874), by Paul Cottin in the *Bulletin du bibliophile* (1894); E. K. Chambers, *Literary Forgeries* (1891); and further references in the *Bibliographie des femmes célèbres* (Turin and Paris, 1892, &c.).

SUS, a province of southern Morocco, once an independent kingdom, and still too unruly to be opened to Europeans, who have nevertheless for centuries past made efforts to secure a foothold. Its principal towns are Tarudant, Iligh (the old capital), and Glimin on the Wad Nun. Tarudant, the present capital, flourished in the 12th century on account of the neighbouring copper-mines. Saltpetre is now the only important product. Ports might be opened at Agadir Ighir (once occupied by the Portuguese for thirty years as Santa Cruz), Massa, Ifni, Arksis and Assaka at the mouth of the Wad Nun. As a coveted district, all kinds of natural riches are attributed to Sus, but it may be assumed that they are exaggerated. Europeans land at their peril, since the coast is by imperial order closed to trade, no custom-house being provided. Most of the business of Sus is carried on at great fairs lasting eight or fifteen days, during which time all roads of approach are guaranteed safe by the tribesmen that trade may be uninterrupted. Caravans from Sus laden with copper-ware, olive oil, butter, saffron, wax, skins, dates, dried roses, &c., are sent to Marrakesh, four days' journey from Tarudant. Susis are well known in the north of Morocco as able tradesmen and clever metal workers. They live frugally, and are only prodigal in powder and human life. Their language is almost exclusively Shilhah, a dialect of Berber. (K.A.M.*)

SUSA (Biblical, *Shushan*), the capital of Susiana or Elam and from the time of Darius I. the chief residence of the Achaemenian kings. It had been the centre of the old monarchy of Elam and had undergone many vicissitudes before it fell into the hands of the Persians (see ELAM). The site, fixed by the explorations of W. K. Loftus, lies in the plain, but within sight of the mountains, between the courses of the Kerkha (Choaspes) and the Dizful, one of the affluents of the Pasitigris. The Shaur, a small tributary of the Dizful, washes the eastern base of the mounds of Shush, and seems to be the representative of the ancient Ulai or Eulaeus. Thus the whole district was fruitful and well watered; the surrounding rivers with their canals gave protection and a waterway to the Persian Gulf; while the position of the town between the Semitic and Iranian lands of the empire was convenient for administrative purposes. Susa therefore became a vast and populous capital; Greek writers assign to it a circuit of 15 or 20 m.

The remains include four mounds, of which one is the site of the citadel called Memnonion by the Greeks, while another (the Apadana to the east of it) represents the palace of Darius I. and Artaxerxes II. *Mnemon*. This latter has been excavated by M. Dieulafoy and the enamelled bricks with which its walls were adorned are now in the Louvre. South of these two mounds is the site of the royal Elamite city. The fourth mound, covering the remains of the poorer houses, is on the right bank of the river between the Shaur and the Kerkha. J. de Morgan's excavations (since 1897) have been principally in the citadel mound, which measures rougnly 1500 ft. by 825 ft. and is 125 ft. high. The two lowest strata belong to the stone age, and the first is characterized by a fine thin pottery, with yellow paste decorated with geometrical patterns and animal or vegetable figures in black and brown-red. Some of it is similar to the prehistoric pottery of Egypt. The pottery of the second neolithic stratum is much inferior. Above these strata come the remains of Elamite and early Babylonian civilization with inscribed objects, the oldest of which exhibit the pictorial characters out of which the cuneiform were evolved. Under the foundations of the temple of In-Susinak (in the north-west part of the mound) a vast quantity of bronze objects has been discovered, for the most part earlier than the 10th century B.C. Among the monuments brought to light in other parts of the mound are the obelisk of Manistusu (see BABYLONIA), the stela of Naram-Sin and the code of Khammurabi, along with a great number of historically valuable boundary-stones. The upper portions of the mounds have yielded, besides Persian remains, Greek pottery and inscriptions of the 4th century B.C., numerous coins of the Kamnaskires dynasty and other kings of Elymais in the Seleucid era, and Parthian and Sassanian relics. In the Sassanian period the city was razed in consequence of a revolt, but rebuilt by Sapor (Shapur) II.; the walls were again destroyed at the time of the Mahommedan conquest, but the site, which is now deserted, was a seat of sugar manufacture in the middle ages.

SUSA (Fr. *Sousse*), a city of Tunisia, on the Gulf of Hammamet, in 35° 49′ N., 10° 39′ E., 36 m. by rail E. by N. of Kairawan, of which it is the port, and 93 m. S. by E. by rail of Tunis. Susa, which occupies part of the site of the ancient Hadrumetum, is built on the side of a hill sloping seawards, and is surrounded by a crenellated wall, strengthened by towers. Recesses in the inner side of the wall are used as shops and warehouses. The kasbah, or citadel, built on the highest point within the town, was thoroughly restored by the French after their occupation of the country in 1881, and serves as military headquarters for the district, the camp for the troops being outside the walls west of the citadel. The native town has been little changed since the French occupation, but north of the port a European quarter has been created, and here are public buildings such as law courts, a museum and a town-hall. The museum contains many archaeological treasures, notable mosaics and sculptures. The most interesting buildings in the old town are the Kasr-er-Ribat and the Kahwat-el-Kubba. The Kasr-er-Ribat is a square fortress with a high tower and seven bastions. Its date is uncertain, but is not later than the 9th century. The Kahwat-el-Kubba (Café of the Dome) is a curious house, square at the base, then cylindrical, and surmounted by a fluted dome. It was probably a church during the Byzantine period. Another domed building, now used as oil-mills, dates from Roman and Byzantine times. In the Bab-el-Gharbi (West Gate) a Roman sarcophagus of marble has been built into the wall, and serves as a drinking fountain. The grand mosque is in the north-east part of the town. The ancient harbours are silted up, but vestiges of the Roman breakwaters may be seen. The modern port, completed in 1901, enables steamers drawing 21 ft. to lie at the quays. Exports are chiefly phosphates and other minerals, olive oil, esparto and cereals; imports: cotton goods, building material, &c. The population, less than 10,000 at the time of the French occupation, had increased in 1907 to over 25,000, of whom 1500 were French and 4000 other Europeans, chiefly Italians and Maltese.

Susa, the Arab town which succeeded Hadrumetum (*q.v.*), was fortified by the Aghlabite rulers of Kairawan in the 9th century A.D. It shared the general fortunes of Tunisia and became a noted haunt of pirates, who raided the coast of Italy. In 1537 it was unsuccessfully besieged by the marquis of Terra Nova, in the service of Charles V., but in 1539 was captured for the emperor by Andrea Doria. As soon as the imperial forces were withdrawn it became again the seat of Turkish piracy. The town was attacked by the French and the Knights of St John in 1770, and by the Venetians in 1764. It remained, however, in the possession of the bey of Tunis.

Some 35 m. due south of Susa, and half way on the road to Sfax is El Jem, the site of the city of Thysdrus. Of the ancient city there are scarcely any remains save the amphitheatre—a magnificent ruin scarcely inferior to that of the Colosseum in Rome. There is no record of the building of the amphitheatre, which is usually assigned to the reign of Gordian III. (A.D. 238–244). It is made of limestone brought from Sallecta, 20 m. distant, bears evidence of hasty construction, and was probably never finished. It is of four storeys—three open arcades crowned by a fourth storey with windows. The first and third arcades are Corinthian; the middle one Composite. Each of these galleries has sixty-four columns and the same number of arches. Constantly used as a fortress since the Arab invasion, the amphitheatre suffered much, and in 1697 the bey of Tunis made a great breach in its western end to prevent it being again used for defence. But even in its present condition the amphitheatre—standing solitary in a desolate district—is grandly impressive. Its major axis is 488 ft., its minor axis 406 ft. (The figures of the Colosseum are 615 and 510½ respectively.)

SUSA (anc. *Segusio*, *q.v.*), a city and episcopal see of Piedmont, Italy, in the province of Turin, from which it is 33 m. W. by rail. Pop. (1901), 3607 (town); 5023 (commune). It is situated on the Dora Riparia, a tributary of the Po, 1625 ft. above sea-level, and is protected from the northern winds by the Rocciamelone. Among the medieval buildings of Susa the first place belongs to the church of San Giusto, founded in 1029 by Olderico Manfredi II. and the countess Berta, and in 1772 raised to be the cathedral. It has a fine brick campanile and brick decoration, and contains a bronze triptych of 1358 in niello, with the Virgin and Child. In the Valle di Susa, about 14 m. east of it, towards Turin, near S. Ambrogio di Torino, is the monastery of S. Michele with a Romanesque church, situated on a rocky mountain (998–1002).

After the time of Charlemagne a marquisate of Susa was established ; and the town became in the 11th century the capital of Adelaide countess of Savoy, who was mistress of the whole of Piedmont. On his retreat from Legnano in 1176 Barbarossa set fire to Susa; but the town became more than ever important when Emmanuel Philibert fortified it at great expense in the 16th century. It was, however, dismantled by Napoleon I. in 1796.

SUSARION, Greek comic poet, a native of Tripodiscus in Megaris. About 580 B.C. he transplanted the Megarian comedy (if the rude extempore jests and buffoonery deserve the name) into the Attic deme of Icaria, the cradle also of Greek tragedy and the oldest seat of the worship of Dionysus. According to the Parian Chronicle, there appears to have been a competition on this occasion, in which the prize was a basket of figs and an amphora of wine. Susarion's improvements in his native farces did not include a separate actor or a regular plot, but probably consisted in substituting metrical compositions for the old extempore effusions of the chorus. These were intended for recitation, and not committed to writing. But such performances did not suit the taste of the Athenians, and nothing more is heard of them until eighty years after the time of Susarion. U. von. Wilamowitz-Möllendorff (in *Hermes*, ix.) considers the so-called Megarian comedy to have been an invention of the Athenians themselves, intended as a satire on Megarian coarseness and vulgarity. The lines attributed to Susarion (in Meineke, *Poetarum comicorum graecorum fragmenta*) are probably not genuine.

SUSO [SEUSE], **HEINRICH** (1300–1366), German mystic, was born of good family at Überlingen on Lake Constance on the 21st of March, in all probability in the year 1300; he assumed the name of his mother, his father being a Herr von Berg. He was educated for the Church, first at Constance, then at Cologne, where he came under the influence of the greatest of the German mystics, Meister Eckart. He subsequently entered a monastery in Constance, where he subjected himself to the severest ordeals of asceticism. In 1335 he wandered through Swabia as a preacher, and won all hearts by his gentle, persuasive eloquence; the effusive lyricism of his language made him an especial favourite among the nuns. About 1348 he seems to have settled in Ulm, where he died on the 25th of January 1366. Suso's first work, *Das Büchlein der Wahrheit*, was written in Cologne about 1329; setting out from Eckart's doctrines, he presents the mystic faith from its speculative or theoretical side; whereas in *Das Büchlein der ewigen Weisheit*, written some years later in Constance, he discusses the practical aspects of mysticism. The latter work, which Suso also translated into Latin under the title of *Horologium sapientiae*, has been called the finest fruit of German mysticism. Suso is the poet of the early mystic movement, "the Minnesinger of *Gottesminne*." But his faith is purely medieval in tone, inspired by the romanticism of the age of chivalry; the individualism, the philosophic insight and the anti-Catholic tendencies which made the mystic movement in its later manifestations so important a forerunner of the Reformation are absent.

Suso's works were collected as early as 1482 and again in 1512; recent editions: Heinrich Suso's *Leben und Schriften*, ed. by M. Diepenbrock (1829; 4th ed., 1884); Suso's *Deutsche Schriften*, by F. H. S. Denifle (1878–1880, not completed), and *Deutsche Schriften*, by K. Bihlmeyer (2 vols., 1907). See also W. Preger, *Die Briefe Heinrich Susos* (1867); W. Preger, *Geschichte der deutschen Mystik* (1882), vol. ii.; J. Jäger, *Heinrich Seuse aus Schwaben* (1894).

SUSPENSURA, the architectural term given by Vitruvius (v. 10) to the hollow space under the floor of a Roman bath, in which the smoke from the furnace passed to the vertical flues in the wall (see HYPOCAUST).

SUSSEX, EARLS OF. The early history of the earldom of Sussex, a title that has been borne at different periods by several English families, is involved in some obscurity, owing to the fact that under the Norman kings the titles of earls were often indifferently derived from a county, from its chief town, or from the earl's principal residence, although the distinctive mark of an earl was deemed to be his right to "the third penny" of the pleas of a county (see EARL). Thus in the 12th century the same person is sometimes found described as earl of Sussex, sometimes as earl of Chichester, and sometimes as earl of Arundel, while the inclusion of the counties of Sussex and Surrey under the jurisdiction of a single sheriff led at one time, as will be seen, to a further confusion between the earldoms of those counties. The difficulty is, again, increased by the Crown's admission in 1433 that the possession of the castle of Arundel carried with it the right to the title of earl of Arundel, though later investigation (see *Lords' Reports on the Dignity of a Peer*, i. 404–429) has proved the invalidity of the claim, and Mr J. H. Round and other modern authorities maintain that inasmuch as Norman earls were earls of counties, the earldom of Arundel was strictly that of Sussex.

On the other hand G. E. Cockayne (*Complete Peerage*, i. 138, 139) holds that Roger de Montgomery, who received grants from William the Conqueror of a large part of the county of Sussex, including the city of Chichester and the castle and honour of Arundel, besides lands in Shropshire with the castles of Shrewsbury and Montgomery, but who does not appear to have had "the third penny" of any county, "was an earl pure and simple, and that, as was usual in those early times, his earldom was indifferently styled either from the territories of Chichester or of Shropshire, or from the castles of Arundel, Shrewsbury or Montgomery." This Roger de Montgomery was considered by Dugdale, a 17th-century authority, to have been earl of Sussex.

Whatever Roger's titles may have been, they were forfeited to the Crown when his son Robert was attainted in 1102, and the forfeited estates were conferred by Henry I. on his second wife Adelicia, who after Henry's death married William de Albini, or d'Aubigny. The latter was created earl of Sussex by King Stephen, and "the third penny" of that county was confirmed to him by an instrument of the reign of Henry II., in which however, he is styled earl of Arundel, a designation by which he was more generally known. His grandson William, 3rd earl of Sussex, was one of King John's sureties for the observance of Magna Carta; and the earldom remained in his family till 1243, when it reverted to the Crown on the death of Hugh de Albini, 5th earl of the line (see ARUNDEL, EARLS OF). This Hugh married Isabel, daughter of William de Warenne, earl of Surrey, who survived him by nearly forty years, during which time she held the estates of the earldom of Sussex in dower; after her death in 1282 her brother John de Warenne, earl of Surrey, was in various writs described as "earl of Surrey and Sussex," the same style being also used by his grandson and successor, another John de Warenne (1286–1347), though it is not clear that either of these Warennes had any right to the Sussex title, the confusion having perhaps arisen through both counties being under the jurisdiction of one sheriff. In any case the earldom of Sussex, if vested in the younger Warenne, reverted to the Crown on his death without legitimate issue in 1347, when his estates devolved on his nephew Richard Fitzalan, earl of Arundel. Since the death of the last earl of the de Albini line in 1243 the earldoms of Arundel and Sussex had been separate.

For nearly two hundred years, from 1347 to 1529, the title of earl of Sussex did not exist in the English peerage. In 1529, however, it was conferred on Robert Radcliffe, Radclyffe or Ratclyffe (*c.* 1483–1542), who had been made Viscount Fitzwalter in 1525. Radcliffe was a son of John Radcliffe, Baron Fitzwalter (*c.* 1452–1496), and a grandson of Sir John Radcliffe of Attleborough in Norfolk, who became Baron Fitzwalter by right of his wife Elizabeth. The younger John Radcliffe shared in the conspiracy of Perkin Warbeck and was beheaded for high treason in 1496. The attainder being reversed in 1506, his son Robert became Baron Fitzwalter in 1506 and was soon a prominent person at the court of Henry VIII. In 1529 he was created earl of Sussex and in 1540 he was appointed great chamberlain of England. He died on the 26th of November 1542, when his son Henry (*c.* 1506–1557) became the 2nd earl. Henry's son, Thomas Radcliffe (see below), became the 3rd earl. Thomas was succeeded in 1583 by his brother Henry (*c.* 1530–1593) who served Elizabeth in Ireland. His son Robert (*c.* 1569–1629), the 5th earl, was a soldier and a patron of men of letters. When Robert's son, Edward, the 6th earl (*c.* 1552–1641), died, the title became extinct, but the barony of Fitzwalter passed to the family of Mildmay, which held it until 1756, when it fell into abeyance.

In 1644 Thomas Savile (*c.* 1590–*c.* 1659), son of John Savile, 1st Baron Savile of Pontefract (1566–1630), was created earl of Sussex. Having been elected to the House of Commons as member for Yorkshire in 1624, Savile became an opponent of Wentworth, afterwards earl of Strafford, the rivalry between the Saviles and the Wentworths having long been a feature of the history of Yorkshire, and attaching himself to the duke of Buckingham, he was created Viscount Savile of Castlebar in the peerage of Ireland in 1628, and two years later succeeded to his father's English peerage. His growing enmity to Strafford led him into violent opposition to the government as the earl's power increased, and in 1640 he entered into correspondence with the Scots, to whom he sent a promise of support to which he forged the signatures of six peers. He was appointed lord president of the council of the north in succession to Strafford, but after the fall of the latter he went over to the Royalist party, in whose interest he exerted his influence in Yorkshire in a manner that brought upon him the displeasure of the parliament in 1642. His efforts to exonerate himself led to his being suspected by the Royalists, and to his arrest, while his residence, Howley Hall, was sacked by Newcastle, the Royalist general. Having been pardoned by Charles, whom Savile attended at Oxford, he was created earl of Sussex in 1644; but his efforts to promote peace on terms distasteful to the king brought him again into disfavour, and in 1645 he was imprisoned and accused of high treason. Escaping from this charge on the ground of his privilege as a peer, he went to London and again ingratiated himself with the popular party. Intriguing simultaneously with both parties, he continued to play a double game with considerable skill, although he suffered imprisonment in 1645 for accusing Holles and Whitelocke of treachery in negotiations with the king, and was heavily fined. After this he retired into private life at Howley Hall, where he died about 1659. He was succeeded in the earldom of Sussex by his son James, on whose death without issue in 1671 the title became extinct. It was revived in 1684 in favour of Thomas Lennard, 15th Baron Dacre, whose wife Ann (d. 1722) was a daughter of the famous duchess of Cleveland by King Charles II., and again became extinct at this nobleman's death in 1715. The title was next conferred in 1717 on Talbot Yelverton, 2nd Viscount de Longueville and 16th Baron Grey de Ruthyn (*c.* 1692–1731), from whom it descended to his two sons successively, becoming once more extinct on the death of the younger of these, Henry, 3rd earl of Sussex of this creation, in 1799.

In 1801 Prince Augustus Frederick (1773–1843) the sixth son of George III., was created duke of Sussex. Spending his early years abroad, the prince was married in Rome in 1793 to Lady Augusta (d. 1830) daughter of John Murray, 4th earl of Dunmore. The ceremony was repeated in London and two children were born, but under the Royal Marriage Act of 1772 the Court of Arches declared the union illegal. The children took the name of d'Este. The son, Sir Augustus Frederick d'Este (1794–1848), became a colonel in the British army. In 1843 he claimed his father's honours, but the House of Lords decided against him. He died unmarried. The daughter, Augusta Emma (1801–1866) married Sir Thomas Wilde, afterwards Lord Truro. Unlike his brothers the duke of Sussex was a man of liberal ideas; he favoured the abolition of the slave trade, the repeal of the corn laws, and the removal of the civil disabilities of Roman Catholics, Dissenters and Jews. His second wife, Cecilia, widow of Sir George Buggin, was created duchess of Inverness in 1840. He died at Kensington Palace on the 21st of April 1843.

The older title of earl of Sussex was revived in 1874 when it was conferred upon Prince Albert, the third son of Queen Victoria, who at the same time was created duke of Connaught and Strathearn.

Tytler, *England under the Reigns of Edward VI. and Mary* (2 vols., London, 1839); *Calendars of State Papers: Letters and Papers of the Reign of Henry VIII.* For the 1st earl of the Savile line see S. R. Gardiner, *Hist. of England, 1603–1642* (10 vols., London, 1883–1884), and *Hist. of the Great Civil War* (3 vols., London, 1886–1891); and John Rushworth, *Historical Collections* (8 vols., London, 1659–1701).

SUSSEX, THOMAS RADCLYFFE [or RATCLYFFE], 3RD EARL OF (*c.* 1525–1583), lord-lieutenant of Ireland, eldest son of Henry, 2nd earl of Sussex (see SUSSEX, EARLS OF), by his first wife, Elizabeth, daughter of Thomas Howard, 2nd duke of Norfolk, was born about 1525, and after his father's succession to the earldom in 1542 was styled Viscount Fitzwalter. After serving in the army abroad, he was employed in 1551 in negotiating a marriage between Edward VI. and a daughter of Henry II., king of France. His prominence in the kingdom was shown by his inclusion among the signatories to the letters patent of the 16th of June 1553 settling the crown on Lady Jane Grey; but he nevertheless won favour with Queen Mary, who employed him in arranging her marriage with Philip of Spain, and who raised him to the peerage as Baron Fitzwalter in August 1553.

Returning to England from a mission to the emperor Charles V. in April 1556, Fitzwalter was appointed lord deputy of Ireland. The prevailing anarchy in Ireland, a country which, nominally subject to the English Crown, was torn by feuds among its practically independent native chieftains, rendered the task of the lord deputy one of no ordinary difficulty; a difficulty that was increased by the ignorance of English statesmen concerning Ireland and Irish conditions, and by their incapacity to devise or to carry into execution any consistent and thoroughgoing policy for bringing the half-conquered island under an orderly system of administration. The measures enjoined upon Fitzwalter by the government in London comprised the reversal of the partial attempts that had been made during the short reign of Edward VI. to promote Protestantism in Ireland, and the "plantation" by English settlers of that part of the country then known as Offaly and Leix. But before Fitzwalter could give his attention to such matters he found it necessary to make an expedition into Ulster, which was being kept in a constant state of disturbance by the Highland Scots from Kintyre and the Islands who were making settlements along the Antrim coast in the district known as the Glynnes (glens), and by the efforts of Shane O'Neill to convert into effective sovereignty the chieftainship of his clan which he had recently wrested from his father, Conn, 1st earl of Tyrone. Having defeated O'Neill and his allies the MacDonnells, the lord deputy, who by the death of his father in February 1557 became earl of Sussex, returned to Dublin, where he summoned a parliament in June of that year. Statutes were passed declaring the legitimacy of Queen Mary, reviving the laws for the suppression of heresy, forbidding the immigration of Scots, and vesting in the Crown the territory comprised in what are now the King's County and Queen's County, which were then so named after Philip and Mary respectively. Having carried this legislation, Sussex endeavoured to give forcible effect to it, first by taking the field against Donough O'Conor, whom he failed to capture, and afterwards against Shane O'Neill, whose lands in Tyrone he ravaged, restoring to their nominal rights the earl of Tyrone and his reputed son Matthew O'Neill, baron of Dungannon (see O'NEILL). In June of the following year Sussex turned his attention to the west, where the head of the O'Briens had ousted his nephew Conor O'Brien, earl of Thomond, from his possessions, and refused to pay allegiance to the Crown; he forced Limerick to open its gates to him, restored Thomond, and proclaimed The O'Brien a traitor. In the autumn of 1558 the continued inroads of the Scottish islanders in the Antrim glens called for drastic treatment by the lord deputy. Sussex laid waste Kintyre and some of the southern Hebridean isles, and landing at Carrickfergus he fired and plundered the settlements of the Scots on the Antrim coast before returning to Dublin for Christmas.

In the metropolis the news reached him of the queen's death. Crossing to England, he took part in the ceremonial of Queen Elizabeth's coronation in January 1559; and in the following July he returned to Ireland with a fresh commission, now as lord lieutenant, from the new queen, whose policy required him to come to terms if possible with the troublesome leaders of the O'Neills and the MacDonnells. Shane O'Neill refused to meet Sussex without security for his safety, and having established his power in Ulster he demanded terms of peace which Elizabeth was unwilling to grant. Sussex failed in his efforts to bring Shane to submission, either by open warfare or by a shameful attempt to procure the Irish chieftain's assassination. He was preparing for a fresh attempt when he was superseded by the earl of Kildare, who was commissioned by Elizabeth to open negotiations with O'Neill, the result of which was that the latter repaired to London and made formal submission to the queen. Shane's conduct on his return to Ireland was no less rebellious than before, and energetic measures against him became more imperative than ever. Having obtained Elizabeth's sanction, Sussex conducted a campaign in the summer of 1563 with Armagh as his temporary headquarters; but except for some indecisive skirmishing and the seizure of many of O'Neill's cattle, the operations led to no result and left Shane O'Neill with his power little diminished. His continued failure to effect a purpose for the accomplishment of which he possessed inadequate resources led Sussex to pray for his recall from Ireland; and his wish was granted in May 1564. His government of Ireland had not, however, been wholly without fruit. Sussex was the first representative of the English Crown who enforced authority to any considerable extent beyond the limits of the Pale; the policy of planting English settlers in Offaly and Leix was carried out by him in 1562 with a certain measure of success; and although he fell far short of establishing English rule throughout any large part of Ireland, he made its influence felt in remote parts of the island, such as Thomond and the Glynnes of Antrim, where the independence of the native septs had hitherto been subjected not even to nominal interference. His letters from Ireland display a just conception of the problems with which he was confronted, and of the methods by which their solution should be undertaken; and his failure was due, not to lack of statesmanship or of executive capacity on his own part, but to the insufficiency of the resources placed at his command and want of insight and persistence on the part of Elizabeth and her ministers.

On his return to England, Sussex, who before leaving Ireland had to endure the indignity of an inquiry into his administration instigated by his enemies, threw himself into opposition to the earl of Leicester, especially in regard to the suggested marriage between that nobleman and the queen. He does not appear to have on that account incurred Elizabeth's displeasure, for in 1566 and the following year she employed him in negotiations for bringing about a different matrimonial alliance which he warmly supported, namely, the proposal that she should bestow her hand on the archduke Charles. When this project fell to the ground Sussex returned from Vienna to London in March 1568, and in July he was appointed lord president of the north, a position which threw on him the responsibility of dealing with the rebellion of the earls of Northumberland and Westmorland in the following year. The weakness of the force at his disposal rendered necessary at the outset a caution which engendered some suspicion of his loyalty; and this suspicion was increased by the counsel of moderation which he urged upon the queen; but in 1570 he laid waste the border, invaded Scotland, and raided the country round Dumfries, reducing the rebel leaders to complete submission. In July 1572 Sussex became lord chamberlain, and he was henceforth in frequent attendance on Queen Elizabeth, both in her progresses through the country and at court, until his death on the 9th of June 1583.

The earl of Sussex was one of the great nobles of the Elizabethan period. Though his loyalty was questioned by his enemies, it was as unwavering as his patriotism. He shone as a courtier; he excelled in diplomacy; he was a man of cultivation and even of scholarship, a patron of literature and of the drama on the eve of its blossoming into the glory it became soon after his death. He was twice married: first to Elizabeth, daughter of Thomas Wriothesley, earl of Southampton; and secondly to Frances, daughter of Sir William Sidney. His second wife was the foundress of Sidney Sussex College at Cambridge, which she endowed by her will, and whose name commemorates the father and the husband of the countess. The earl left no children, and at his death his titles passed to his brother Henry (see SUSSEX, EARLS OF).

(R. J. M.)

SUSSEX, a southern county of England, bounded N. by Surrey, N.E. by Kent, S. by the English Channel, and W. by Hampshire. The area is 1459·2 sq. m. The extreme length from E. to W. is 78 m., while the breadth never exceeds 28 m., but the county is not wholly on the southward slope, for in the middle northern district it contributes a small drainage area to the Thames basin, and the river Medway rises in it. A line of hills known as the Forest Ridges forms the watershed. Its direction is E.S.E. from the northern part of the county to the coast at Fairlight Down east of Hastings, and it reaches a height of about 800 ft. in the neighbourhood of Crowborough. The salient physical feature of the county, however, is the hill range called the South Downs (see DOWNS). Entering in the west, where its summit is about 10 m. from the sea, it runs east for some 50 m., gradually approaching the coast, and terminating in the bold promontory of Beachy Head near Eastbourne. The average height is about 500 ft., though some summits exceed 700, and Ditchling Beacon is over 800. The portion of the county north of the South Downs is called the Weald (*q.v.*). It was formerly covered with forest, and this part of the county is still well wooded. About 1660 the total area under forest was estimated to exceed 200,000 acres, but much wood was cut to supply the furnaces of the ironworks which formed an important industry in the county down to the 17th century, and survived even until the early years of the 19th.

The rivers wholly within the county are small. All rise in the Forest Ridges, and all, except the Rother, which forms part of the boundary with Kent, and falls into the sea below Rye, breach the South Downs. From east to west they are the Cuckmere, rising near Heathfield; the Ouse, Adur and Arun, all rising in the district of St Leonard's Forest, and having at their mouths the ports of Newhaven, Shoreham and Littlehampton respectively. The natural trench known as the Devil's Dike is a point greatly favoured by visitors from Brighton. The coast-line is practically coextensive with the extreme breadth of the county, and its character greatly varies. The sea has done great damage by incursion at some points, and has receded in others, within historic times. Thus what is now marshland or "Levels" round Pevensey was formerly an island-studded bay. In the east Winchelsea and Rye, members of the Cinque Ports, and great medieval towns, are deprived of their standing, the one wholly and the other in part, since a low flat tract interposes between their elevated sites where formerly was a navigable inlet. Yet the total submergence of the site of Old Winchelsea was effected in the 13th century. The site of the ancient cathedral of Selsey is a mile out at sea. Between 1292 and 1340 upwards of 5500 acres were submerged. In the early part of the 14th century Pagham Harbour was formed by a sudden irruption of the sea, devastating 2700 acres, since reclaimed. There is reason to believe that the whole coastline has subsequently been slightly raised. These changes are reflected in the numerous alterations recorded in the course of certain of the rivers near their mouths. Thus the Rother was diverted by a great storm on the 12th of October 1250, before which date it entered the sea 12 m. to the east. The outlet of the Ouse was at Seaford until 1570, and that of the Adur formerly shifted from year to year, ranging east and west over a distance of 2 m. Submerged forests are found off the shore at various points. Long stretches of firm sand, and the mild climate of the coast, sheltered by the hills from north and east winds, have resulted in the growth of numerous watering-places, of which the most popular are Brighton, Hastings, Eastbourne, Bexhill, Seaford, Shoreham, Worthing, Littlehampton and Bognor.

Geology.—The disposition of the rock formations of Sussex is simple. The South Downs consist of chalk, which extends from Beachy Head by Seaford, Brighton, Lewes, Steyning and Goodwood to the western border. The dip of the chalk is southerly, while a strong escarpment faces the north. From the summit of the Downs the hilly country observed on the northern side is occupied mainly by the Hastings Beds and the Weald Clay; at the foot of the escarpment lie the Gault and Upper Greensand, while between these formations and the Wealden rocks there is an elevated ridge of ground formed by the Lower Greensand. On the southern side, narrow at Brighton but broadening westward, is a level tract, 8 m. wide in the peninsula of Selsey, which owes its level character to the action of marine planation. This tract is occupied partly by Chalk and partly by Tertiary rocks, both much obscured by more recent deposits. On this side the chalk hills are deeply notched by dry valleys or coombs, which frequently end in cirques near the northward escarpment. The present aspect of the strata has been determined by the broad east and west fold with its subordinate members, known as the Wealden anticline. Only the southern and central portions of this anticline are included in this country; at one time there is no doubt that the Chalk, Greensand and Gault covered the entire area in the form of an uplifted dome, but denudation has removed the Chalk and most of the other formations as far as the North Downs, exposing thereby the underlying Wealden Beds. The oldest rocks thus brought to light along the crest of the anticline are the Purbeck Beds, small patches of shale and limestone, with some important beds of gypsum, which lie north-west of Battle. A deep boring (1905 ft.) at Netherfield, passed through Portlandian Beds and Kimmeridge Clay into Oxford Clay, but these do not appear anywhere at the surface. Above the Purbeck Beds, and covering all the north-eastern portion of the county from the coast at Bexhill and Rye to Horsham, are sands and clays of the Lower Wealden or Hastings Beds. This includes the following local subdivisions, in ascending order; the Fairlight Clay, Ashdown Sand, Wadhurst Clay, Lower Tunbridge Wells Sand, Grinstead Clay and Upper Tunbridge Wells Sand (with Tilgate stone at the top and Cuckfield Clay at the base). The Weald Clay occupies a belt of lower ground on the south and west of the Hastings Sands, it consists of blue and mottled clays with thin sand layers and beds of hard limestone, the "Sussex marble" with the shells of *Paludina*. The Horsham Stone is another local hard bed. Near Tilgate the remains of *Iguanodon* have been found in this formation. Bordering the outcrop of the Weald Clay is the Lower Greensand; it appears a little north of Eastbourne and passes thence through Ringmer, Storrington, Pulborough, Petworth, Midhurst and Linchmere. It contains the following divisions in ascending order—the Atherfield Clay, Hythe Beds (sandy limestone, sandstone and chert), Sandgate Beds and Folkestone Beds. The Eocene strata lying south of the Downs and west of Brighton—with the exception of some outliers of Reading Beds near Seaford—include the Woolwich and Reading Beds, London Clay (with hard "Bognor Rock"), the Bagshot and Bracklesham Beds; the last-named formation is very fossiliferous in the bay of that name. As already mentioned, superficial deposits cover much of the low ground west of Brighton; these include glacial deposits with large boulders, raised beaches, brick earth and gravels, marine and estuarine, and the interesting Coombe rock or Brighton Elephant Bed, a coarse rubble of chalk waste formed late in the Glacial period, well exposed in the cliff at Black Rock east of Brighton, where it rests on a raised beach. The natural gas of Heathfield comes from the Lower Wealden and Purbeck Beds. The Wadhurst Clay was formerly an important source of iron ore.

Climate and Agriculture.—The climate of the coast district is mild, equable and dry, while that of the Wealden shows greater extremes of temperature, and is rather wetter. The mean daily range of temperature in the Weald is about half as much again as on the coast. The influence of the sea in modifying the temperature of the coast district is specially noticeable in the autumn months, when the temperature is higher than in the Weald and other parts of England northwards. The coast district is specially suitable for market gardens and for growing fruit trees. The fig gardens of West Tarring are celebrated. About seven-tenths of the total area is under cultivation, and of this nearly three-fifths is in permanent pasture. Sussex is still one of the best-wooded counties in England. The acreage under grain crops shows a large decrease; nearly the whole of it is occupied by oats and wheat. The acreage under green crops is mainly devoted to turnips and other food for cattle and to the supply of vegetables for the London market. The growing of hops has not kept pace with that in the neighbouring county of Kent. Cattle are kept in increasing numbers both for breeding and for dairy purposes. The South Downs afford excellent pasture for sheep and Sussex is famed for a special breed of black-faced sheep. The numbers, however, show a steady decrease. Poultry farming is largely carried on in some parts. The custom of borough-English, by which land descends to the youngest son, prevailed to an extraordinary degree in Sussex, and no fewer than 140 manors have been catalogued in which it was found. Gavelkind tenure existed in Rye, in the large manor of Brede, and in Coustard manor (in Brede parish).

Other Industries.—The manufacturing industries are meagre. The London, Brighton & South Coast Railway Company has large works at Brighton. At Heathfield in 1901 the development of the field of natural gas was begun by a private company. The fisheries are of great importance, including cod, herrings, mackerel, sprats, plaice, soles, turbot, shrimps, crabs, lobsters, oysters, mussels, cockles, whelks and periwinkles. Bede records that St Wilfrid, when he visited the county in 681, taught the people the art of net-fishing. At the time of the Domesday survey the fisheries were extensive, and no fewer than 285 *salinae* (saltworks) existed. The customs of the Brighton fishermen were reduced to writing in 1579.

Communications.—Communications are provided by the London, Brighton & South Coast railway by lines from the north to St Leonards and Hastings, to Eastbourne, to Lewes and Newhaven, to Brighton, to Shoreham, and to Arundel and Chichester, with numerous branches and a connecting line along the coast. The South-Eastern & Chatham railway serves Bexhill, St Leonards and Hastings, with a coastal branch eastward by Rye. Light railways run from Chichester to Selsey (Selsey railway) and from Robertsbridge to Bodiam and Tenterden (Rother Valley railway). There are no good harbours, and none of the ports is of first importance. From Newhaven, however, a large trade is carried on with France, and daily services of passenger steamers of the Brighton Railway Company ply to Dieppe.

Population and Administration.—The area of the ancient county is 933,887 acres, with a population in 1891 of 550,446 and in 1901 of 605,202. The earliest statement as to the population is made by Bede, who describes the county as containing in the year 681 land of 7000 families; allowing ten to a family (not an unreasonable estimate at that date), the total population would be 70,000. In 1693 the county is stated to have contained 21,537 houses. If seven were allowed to a house at that date, the total population would be 150,759. It is curious, therefore, to observe that in 1801 the population was only 159,311. The decline of the Sussex ironworks probably accounts for the small increase of population during several centuries, although after the massacre of St Bartholomew upwards of 1500 Huguenots landed at Rye, and in 1685, after the revocation of the Edict of Nantes, many more refugees were added to the county.

An act of Henry VII. (1504) directed that for convenience the county court should be held at Lewes as well as at Chichester, and this apparently gave rise to the division of Sussex into east and west parts, each of which is an administrative county. East Sussex has an area of 528,807 acres and West Sussex of 403, 602 acres. Sussex includes the county boroughs of Brighton and Hastings. East Sussex contains the municipal boroughs of Bexhill (pop. 12,213), Brighton (123,478), Eastbourne (43,344), Hastings (65,528), Hove (36,535), Lewes (11,249) and Rye (3900). The urban districts in this division are Battle (2996), Burgess Hill (4888), Cuckfield (1813), East Grinstead (6094), Haywards Heath (3717), Newhaven (6772), Portslade-by-Sea (5217), Seaford (3355) and Uckfield (2895). In West Sussex the municipal boroughs are Arundel (2739), Chichester, a city (12,244) and Worthing (20,015). The urban districts are Bognor (6180), Horsham (9446), Littlehampton (7363), Shoreham (3837) and Southwick (3364). The ancient county, which is almost entirely in the diocese of Chichester, contains 377 ecclesiastical parishes or districts, wholly or in part. The total number of civil parishes is 338. Sussex is divided into the following parliamentary divisions: northern or East Grinstead, eastern or Rye, southern or Eastbourne, mid or Lewes, south-western or Chichester, north-western or Horsham, each returning one member; and contains the parliamentary boroughs of Brighton, returning two members, and Hastings, returning one.

History.—Apart from conclusions to be drawn from prehistoric remains, the history of Sussex begins in 477, when the Saxons landed in the west of the county under Ella and his three sons, and built up the kingdom of the South Saxons (see SUSSEX, KINGDOM OF, below). They took the Roman city of Regnum, which became Chichester, and drove the British westward, into the forest of Andred. The Roman fortress of Anderida, the site of the castle of Pevensey, also fell to the Saxons. Ella became the most influential of the contemporary Saxon chiefs, and was, according to Bede, the first Bretwalda. After his time the kingdom of Sussex gradually declined, and fell entirely under the dominion of Wessex in 823. Interesting Saxon remains are found in numerous cemeteries, and scattered burial places along the south slopes of the Downs. The cemetery on High Down hill, where weapons, ornaments and vessels of various kinds were found, and the Chanctonbury hoard of coins, are among the most noticeable relics. A coin of Offa of Mercia, found at Beddingham, recalls the charter of Archbishop Wilfred in 825, in which Offa's connexion with the monastery in that place is recorded. From 895 Sussex suffered from constant raids by the Danes, till the accession of Canute, after which arose the two great forces of the house of Godwine and of the Normans. Godwine was probably a native of Sussex, and by the end of the Confessor's reign a third part of the county was in the hands of his family. Norman influence was already strong in Sussex before the Conquest; the harbours of Hastings, Rye, Winchelsea and Steyning being in the power of the Norman abbey of Fécamp, while the Norman chaplain of Edward the Confessor, Osbern, afterwards bishop of Exeter, held the estate of Bosham.

The county was of great importance to the Normans; Hastings and Pevensey being on the most direct route for Normandy. William was accordingly careful to secure the lines of communication with London by placing the lands in the hands of men bound by close ties to himself, such as his half-brother, the count of Mortain, who held Pevensey, and his son-in-law, William de Warenne, who held Lewes. With the exception of lands held by the Church and the Crown, the five rapes of Sussex were held by these and three other Norman tenants-in-chief: William de Braose, the count of Eu, and Roger, earl of Montgomery, who held respectively Bramber, Hastings and Arundel. The honour of Battle was afterwards made into a rape by the Conqueror, and provides one of the arguments in favour of the theory of the Norman origin of these unique divisions of the county. The county was divided into five (afterwards six) strips, running north and south, and having each a town of military, commercial and maritime importance. These were the rapes, and each had its sheriff, in addition to the sheriff of the whole county. Whether the origin of the rapes, as districts, is to be found in the Icelandic territorial division *hreppr* (rejected in the *New English Dictionary*), or in the Saxon *rap*, a rope, or is of Norman origin, as lordships they undoubtedly owed their existence to the Normans. The holdings—which had been scattered under the Saxons, so that one man's holding might be in more than one rape—were now determined, not by the manors in which they lay, but by the borders of the rape. Another peculiarity of the division of land in Sussex is that, apparently, each hide of land had eight instead of the usual four virgates.

The county boundary was long and somewhat indeterminate on the north, owing to the dense forest of Andredsweald, which was uninhabited till the 11th century. Evidence of this is seen in Domesday Book by the survey of Worth and Lodsworth under Surrey, and also by the fact that as late as 1834 the present parishes of north and south Amersham in Sussex were part of Hampshire. At the time of the Domesday Survey Sussex contained sixty hundreds, which have been little altered since. A few have been split up into two or three, making seventy-three in all; and the names of some have changed, owing probably to the meeting-place of the hundred court having been altered. These courts were in private hands in Sussex; either of the Church, or of great barons and local lords. The county court was held at Lewes and Shoreham until the Great Inquest, when it was moved to Chichester. After several changes the act of 1504 arranged for it to be held alternately at Lewes and Chichester. There was no gaol in the county until 1487; that at Guildford being used in common by Surrey and Sussex, which were under one sheriff until 1567.

Private jurisdictions, both ecclesiastical and lay, played a large part in the county. The chief ecclesiastical franchises were those of the archbishop of Canterbury, of the bishop of Chichester, of the Saxon foundation of Bosham, where Bishop Wilfred had found the only gleam of Christianity in the county, and of the votive abbey of Battle, founded by the Conqueror. This abbey possessed, besides land in many other counties, the "Lowy of Battle," a district extending for 3 m. round the abbey. The see of Chichester was co-extensive with the county, and has altered little. It is one of the oldest bishoprics, having been founded by Wilfred at Selsey; the seat was removed to Chichester by William I. Among the lay franchises, the most noticeable are those of the Cinque Ports and of the honor of Pevensey, named the honor of the Eagle from the lords of L'Aigle or Aguila.

Sussex, from its position, was constantly the scene of preparations for invasion, and was often concerned in rebellions. Pevensey and Arundel play a great part in rebellions and forfeiture during the troubled times of the early Norman kings. In the barons' wars the county was a good centre for the king's forces; Lewes being in the hands of the king's brother-in-law, John de Warenne, earl of Surrey, Pevensey and Hastings in those of his uncle, Peter of Savoy. The forces of the king and of De Montfort met at Lewes, where the famous battle and "Mise of Lewes" took place. The corrupt and burdensome administration of the county during the 13th and 14th centuries, combined with the constant passage of troops for the French wars and the devastating plagues of the 14th century, were the causes of such rebellions as the Peasants' Rising of 1381 and Jack Cade's Rebellion in 1450. In the former Lewes Castle was taken, and in the latter we find such men engaged as the abbot of Battle and the prior of Lewes. During Elizabeth's reign there was again constant levying of troops for warfare in Flanders and the Low Countries, and preparations for defence against Spain. The sympathies of the county were divided during the Civil War, Arundel and Chichester being held for the king, Lewes and the Cinque Ports for the parliament. Chichester and Arundel were besieged by Waller, and the Roundheads gained a strong hold on the county, in spite of the loyalty of Sir Edward Ford, sheriff of Sussex. A royalist gathering in the west of the county in 1645 caused preparations for resistance at Chichester, of which Algernon Sidney was governor. In the same year the "Clubmen" rose and endeavoured to compel the armies to come to terms. Little active part in the national history fell to Sussex from that time till the French Revolution, when numbers of volunteers were raised in defence. At the outbreak of war with France in 1793 a camp was formed at Brighton; and at Eastbourne in 1803, when the famous Martello towers were erected.

The parliamentary history of the county began in 1290, for which year we have the first extant return of knights of the shire for this county, Henry Hussey and William de Etchingham, representatives of two well-known Sussex families, being elected. Drastic reformation was effected by the Redistribution Act of 1832, when Bramber, East Grinstead, Seaford, Steyning and Winchelsea were disfranchised after returning two members each, the first being classed among the worst of the "rotten" boroughs. Before 1832 two members each had been returned also by Arundel, Chichester, Hastings, Horsham, Lewes, Midhurst, New Shoreham (with the rape of Bramber) and Rye. Arundel, Horsham, Midhurst and Rye were each deprived of a member in 1832, Chichester and Lewes in 1867, and Hastings in 1885. Arundel was disfranchised in 1868, and Chichester, Horsham, Midhurst, New Shoreham and Rye in 1885. In the 18th century the duke of Newcastle was all-powerful in the county, where the Pelham family had been settled from the time of Edward I.; the earl of Chichester being the present representative of the family. Among the oldest county families of Sussex may be mentioned the Ashburnhams of Ashburnham, the Gages of Firle and the Barttelots of Stopham.

The industries of Sussex, now mainly agricultural, were once varied. Among those noted in the Domesday Survey were the herring fisheries, the salt pans of the coast and the wool trade; the South Down sheep being noted for their wool, at home and abroad, as early as the 13th century. The iron mines of the county, though not mentioned in Domesday, are known to have been worked by the Romans; and the smelting and forging of iron was the great industry of the Weald from the 13th to the 18th century, the first mention of the trade in the county being in 1266. In the 15th century ordnance for the government was made here. Some old banded guns with the name of a Sussex maker on them may be seen at the Tower of London. The first cast-iron cannon made in England came from Buxted in Sussex, and were made by one Ralph Hogge, whose device can be seen on a house in Buxted. The large supply of wood in the county made it a favourable centre for the industry, all smelting being done with charcoal till the middle of the 18th century. In the time of Henry VIII. the destruction of the forest for fuel began to arouse attention, and enactments for the preservation of timber increased from this time forward, till the use of pit-coal for smelting was perfected, when the industry moved to districts where coal was to be found. Camden, Thomas Fuller, and Drayton in his *Polyolbion* refer to the busy and noisy Weald district, and lament the destruction of the trees. The glass-making industry, which had flourished at Chiddingfold in Surrey, and at Wesborough Green, Loxwood and Petworth in Sussex, was destroyed by the prohibition of the use of wood fuel in 1615. The timber trade had been one of the most considerable in early times; the Sussex oak being considered the finest shipbuilding timber. Among the smaller industries weaving and fulling were also to be found, Chichester having been noted for its cloth, also for malt and needles.

Antiquities.—From early times castles guarded three important entries from the coast through the South Downs into the interior provided by the valleys of the Ouse, the Adur and the Arun. These are respectively at Lewes, Bramber and Arundel. The ruins of the first two, though imposing, do not compare in grandeur with the third, which is still the seat of the dukes of Norfolk. More famous than these are the massive remains, in part Norman but mainly of the 13th century, of the stronghold of Pevensey, within the walls of Roman Anderida. Other ruins are those of the finely situated Hastings Castle; the Norman remains at Knepp near West Grinstead; the picturesque and remarkably perfect moated fortress of Bodiam, of the 14th century; and Hurstmonceaux Castle, a beautiful 15th-century building of brick. Specimens of ancient domestic architecture are fairly numerous; such are the remnants of old palaces of the archbishops of Canterbury at Mayfield and West Tarring; Amberley Castle, a residence until the 16th century of the bishops of Chichester; and the Elizabethan mansions of Parham and of Danny at Hurstpierpoint. There are many fine residences dating from the 18th century or later; Goodwood is perhaps the most famous. Here and elsewhere are fine collections of paintings, though the county suffered a loss in this respect through the partial destruction by fire of the modern castle of Knepp in 1904.

Monastic remains are few and generally slight. The ruins of Bayham Abbey near Tunbridge Wells, and of Battle Abbey, may be noticed. There are numerous churches, however, of great interest and beauty. Of those in the towns may be mentioned the cathedral of Chichester, the churches of Shoreham and Rye, and the mother church of Worthing at Broadwater. Construction of pre-Norman date is seen in the churches of Bosham, Sompting and, most notably, Worth. There is very rich Norman work of various dates in the church of St Nicholas, Steyning. Several perfect specimens of small Early English churches are found, as at West Tarring, and at Climping near Littlehampton. Perhaps the most interesting church in the county is the magnificent Decorated fragment at Winchelsea; another noteworthy church of this period is at Etchingham, near the eastern border. The church of St Denis, Midhurst, is mainly Perpendicular; but this style is not otherwise predominant. The large church at Fletching, of various styles, contains the tomb of Gibbon the historian. At Cowfold, south-east of Horsham, is a great Carthusian monastery, founded in 1877. The iron memorial slabs occurring in several churches recall the period of the iron industry in Sussex.

Dialect.—A large number of Saxon words are retained and pronounced in the old style; thus *gate* becomes *ge-at*. The letter *a* is very broad in all words, as if followed by *u*, and in fact converts words of one syllable into words of two, as *faüs* (face), *taüst* (taste), &c. Again, *a* before double *d* becomes *ar*, as *arder* and *larder* for *adder* and *ladder*; *oi* is like a long *i*, as *spile* (spoil), *intment* (ointment); an *e* is substituted for *a* in such words as *rag*, *flag*, &c. The French refugees in the 16th and 17th centuries introduced many words which are still in use. Thus a Sussex woman when unprepared to receive visitors says she is in *dishabille* (déshabillé, undress); if her child is unwell, it looks *pekid* (piqué), if fretful, is a little *petergrievous* (petit-grief); she cooks with a *broach* (broche, a spit), and talks of *coasts* (coste, O. Fr.), or ribs of meat, &c.

Hare, *Sussex* (London, 1894).

SUSSEX, KINGDOM OF (*Súð Seaxe, i.e.* the South Saxons), one of the kingdoms of Anglo-Saxon Britain, the boundaries of which coincided in general with those of the modern county of Sussex. A large part of that district, however, was covered in early times by the forest called Andred. According to the traditional account given in the Anglo-Saxon Chronicle, it was in 477 that a certain Ella (Ælle) led the invaders ashore at a place called Cymenes ora and defeated the inhabitants. A further battle at a place called Mearcredes burne is recorded under the year 485, and in the annal for 491 we read that Ella and Cissa his son sacked Anderida and slew all the inhabitants. Ella is the first king of the invading race whom Bede describes as exercising supremacy over his fellows, and we may probably regard him as an historical person, though little weight can be attached to the dates given by the Chronicle.

The history of Sussex now becomes a blank until 607, in which year Ceolwulf of Wessex is found fighting against the South Saxons. In 681 Wilfrid of York, on his expulsion from Northumbria by Ecgfrith, retired into Sussex, where he remained until 686 converting its pagan inhabitants. According to Bede, Æthelwald, king of Sussex, had been previously baptized in Mercia at the suggestion of Wulfhere, who presented him with the Isle of Wight and the district about the Meon. After Wilfrid's exertions in relieving a famine which occurred in Sussex the king granted to him eighty-seven hides in and near the peninsula of Selsey which, with a lapse until 709 after Wilfrid's retirement, remained the seat of the South Saxon bishopric until the Norman Conquest. Shortly afterwards, however, Æthelwald was slain and his kingdom ravaged by the exiled West Saxon prince Ceadwalla. The latter was eventually expelled by two princes named Berhthun and Andhun, who thereupon assumed the government of the kingdom. In 686 the South Saxons attacked Hlothhere, king of Kent, in support of his nephew Eadric, but soon afterwards Berhthun was killed and the kingdom subjugated for a time by Ceadwalla, who had now become king of Wessex.

Of the later South Saxon kings we have little knowledge except from occasional charters. In 692 a grant is made by a king called Nothelm to his sister, which is witnessed by two other kings called Nunna and "Uuattus." Nunna is probably to be identified with Nun, described in the Chronicle as the kinsman of Ine of Wessex who fought with him against Gerent, king of the West Welsh, in 710. According to Bede, Sussex was subject to Ine for a number of years. A grant, dated by Birch about 725, is made by Nunna to Eadberht, bishop of Selsey, and to this too "Uuattus" appears as a witness. In 722 we find Ine of Wessex at war with the South Saxons, apparently because they were supporting a certain Aldbryht, probably an exile from Wessex. An undated grant is made by Nunna about this time, which is witnessed by a King Æthelberht. After this we hear nothing more until shortly before 765, when a grant of land is made by a king named Aldwulf with two other kings, Aelfwald and Oslac, as witnesses. In 765 and 770 grants are made by a King Osmund, the latter of which is witnessed by Offa of Mercia. Offa also appears as witness to two charters of an Æthelberht, king of the South Saxons, and in 772 he grants land himself in Sussex, with Oswald, *dux* of the South Saxons, as a witness. It is probable that about this time Offa definitely annexed the kingdom of Sussex, as several persons, Osmund, Ælfwald and Oslac, who had previously used the royal title, now sign with that of *dux*. In 825 the South Saxons submitted to Ecgberht, and from this time they remained subject to the West Saxon dynasty. The earldom of Sussex seems later to have been held sometimes with that of Kent.

Authorities.—*Anglo-Saxon Chronicle*, pp. 449, 477, 485, 491, 607, 722, 725, 823, 827 (ed. Earle and Plummer, Oxford, 1899); Bede, *Historia Ecclesiastica*, i. 15, ii. 5, iv. 13, 15, 16, 26, v. 18, 19, 23 (ed. C. Plummer, Oxford, 1896); W. de G. Birch, *Cartularium Saxonicum*, Nos. 78, 144, 145, 197, 198, 206, 208, 211, 212, 1334 (London, 1885–1893). (F. G. M. B.)

SUTHERLAND, EARLS AND DUKES OF. The first earl of Sutherland was a certain William (d. 1284), whose father, Hugh Freskin (d. 1204), acquired the district of Sutherland about 1197. Probably about 1230 William was created earl of Sutherland. His descendant William, the 4th earl (d. 1370), was a person of some importance in the history of Scotland; he married Margaret (d. 1358), daughter of King Robert Bruce. His descendant John, the 9th earl, a man of weak intellect, died unmarried in 1514.

John's sister Elizabeth (d. 1535) married Adam Gordon (d. 1537), a younger son of George Gordon, 2nd earl of Huntly, and a grandson of King James I., and before 1516 Gordon became earl of Sutherland by right of his wife. He was succeeded by his grandson John (*c.* 1526–1567), the 2nd earl of his line, who played his part in the turbulent politics of the time and was poisoned at the instigation of George Sinclair, 4th earl of Caithness. His great-grandson John, the 5th earl (1609–1663), was a strong Covenanter, being called by his associates "the good Earl John"; he fought against Montrose at Auldearn, but afterwards he rendered good service to Charles II. John Gordon (*c.* 1660–1733), who became the seventh earl in 1703, supported the revolution of 1688 and was a commissioner for the union of England and Scotland. He was a Scottish representative peer in four parliaments, president of the board of trade and manufactures, and lord-lieutenant of the eight northern counties of Scotland. He was active in putting down the rising of 1715. This earl, who took the name of Sutherland instead of that of Gordon, was succeeded by his grandson William (*c.* 1708–1750), a representative peer, who helped to suppress the rebellion of 1745. William, the next earl, died without male issue in 1766. This earl's daughter Elizabeth (1765–1839) claimed the peerage, and although her title thereto was contested by Sir Robert Gordon, Bart., a descendant of the first Gordon earl, it was confirmed by the House of Lords in 1771.

Established in the possession of the title and the vast estates of the earldom, the countess of Sutherland was married in 1785 to George Granville Leveson-Gower (1758–1833), who succeeded his father as second marquess of Stafford in 1803. In addition to the estates of the marquessate of Stafford, Leveson-Gower inherited the Bridgewater Canal and estates from his maternal uncle, Francis Egerton, 2nd duke of Bridgewater, and these properties, together with his wife's estates, which included almost the whole of the county of Sutherland, made him a "leviathan of wealth," as he is called by Charles Greville. In 1833 he was created duke of Sutherland. Leveson-Gower was a member of parliament from 1778 to 1784 and again from 1787 to 1798 and was British ambassador in Paris from 1790 to 1792. From 1799 to 1810 he was joint postmaster-general. He was a collector of paintings, and purchased Stafford House, still the London residence of the dukes of Sutherland. As a landlord he greatly improved his estates in Staffordshire and Shropshire and then turned his attention to those of his wife in Sutherlandshire. He was responsible for the construction of about 450 m. of road and of many bridges, but his policy of removing a large number of his tenants from the interior to the coast aroused bitterness and criticism. However, he reduced rents and brought thousands of acres into cultivation. He died at Dunrobin Castle on the 5th of July 1833.

His elder son, George Granville (1786–1861), became the 2nd duke, but the valuable Bridgewater estates passed to his younger son, Lord Francis Leveson-Gower, who was created earl of Ellesmere in 1846. The 2nd duke's wife, Harriet Elizabeth Georgiana (1806–1868), a daughter of George Howard, 6th earl of Carlisle, was one of Queen Victoria's most intimate friends. She was mistress of the robes to the queen, whose refusal to part with her in 1839 led to a ministerial crisis. Some of her letters are published in *Stafford House Letters*, edited by her son Lord Ronald Gower (1891).

George Granville William, the 3rd duke (1828–1892), spent large sums in improving his estates. His wife Anne (1829–1888), daughter of John Hay Mackenzie, was created countess of Cromartie in 1861, and the earldom descended to her second son Francis (1852–1893). When he died without sons the earldom fell into abeyance, but this was terminated in 1895 in favour of his daughter Sibell Lilian (b. 1878), the author of *The Days of Fire* and other books.

In 1892 Cromartie Leveson-Gower (b. 1851), who had been M.P. for Sutherlandshire, became 4th duke of Sutherland. His wife, Millicent Fanny, daughter of the 4th earl of Rosslyn, became well known in literary as well as in social and philanthropic circles.

See Sir Robert Gordon and George Gordon, *Genealogical History of the Earldom of Sutherland* (Edinburgh, 1813); and also the article STAFFORD, EARLS AND MARQUESSES OF.

SUTHERLANDSHIRE, a northern county of Scotland, bounded N. and W. by the Atlantic, E. by Caithness, S.E. by the North Sea and S. by the shire of Ross and Cromarty. It has an area of 1,297, 846 acres or 2,028 sq. m., being the fifth largest shire in Scotland. The western and northern shores are much indented and terminate at many points in precipices and rugged headlands. The mountains are distinguished by grandeur of outline. Ben More (3273 ft.) in Assynt is the highest in the shire, and next to it in height is Ben Clibreck (3154). Ben Hope (Icelandic *hôp*, haven, 3040), in the north, is noted as the only place in Great Britain where the Alpine *Alsine rubella* is found, and also for its fauna, ptarmigan being common, and even the wild cat and golden eagle occurring at rare intervals. Other lofty hills include Foinaven (wart mountain, 2980) in the north-west; Ben Hee (2864), the highest point in Reay Forest; the serrated ridge of Quinag (2653) and Glasven (2541) north, and the cone of Canisp (2779) south of Loch Assynt; the precipitous Carn Stackie (2630) in Durness; Ben Arkle (2580) and Ben Stack (2364), frowning above Loch Stack; the fantastic peaks of Ben Loyal (the hill of the young calves, or deer, 2504) in Tongue; and Suilven (2399). The greater part of the mountainous region consists of wild and desolate moorlands. The chief river is the Oykell, which, rising in Coniveall (3234), a peak of Ben More, flows south and then south-east for 33 m. to Dornoch Firth, forming the major part of the southern boundary of the shire. Its principal left-hand tributaries are the Shin and Cassley. Other rivers flowing to Dornoch Firth are the Helmsdale (22 m.), issuing from Loch an Ruathair; the Brora (28 m.), rising in Mt Uaran and preserving in its name (bridge river) the fact that its bridge was once the only important one in the county; and the Fleet (17), the head of the estuary of which was embanked for 1000 yds. in 1813 by Thomas Telford, whereby a considerable tract of rich alluvial land was reclaimed from the sea. The longest rivers flowing to the north coast are the Dionard (14) to Kyle of Durness, the Naver (17) to Torrisdale Bay, and the Halladale (22), rising in Knockfin on the borders of Caithness and entering the sea to the east of Portskerry. Much of the surface in the district of Assynt is honeycombed with lakes and tarns, but the only large lake is Loch Assynt, which is 6½ m. long, lies 215 ft. above the sea, has a drainage area of 43 sq. m., and a greatest depth of 282 ft., and empties into the sea by the Inver. Other lakes are Loch Crocach, little more than 1 m. long by ⅓ m. wide, in which the ratio of the area of islands to the total area of the loch is greater than in any other British lake; Loch Shin (17 m. long); Loch Loyal (4 m.); Loch Hope (6 m.); Loch Naver (6 m.); and Loch More (4 m.). The principal inlets of the sea are, on the north coast, Kyle of Tongue—on the east shore of which stands Tongue House, once the property of the Reay family, now a seat of the duke of Sutherland—Loch Eriboll and Kyle of Durness; on the west, Lochs Inchard, Laxford (salmon fjord), Cairnbawn, Glendhu, Glencoul, Eddrachilis Bay and Loch Inver; and, on the south-east, Loch Fleet. There are many waterfalls in the county. Those of Escuallin, near the head of Glencoul, are among the finest in Great Britain. There are three principal capes—Strathy Point on the north; Cape Wrath at the extreme north-west; and Ru Stoer, near which is the Old Man of Stoer, a detached pillar of rock about 250 ft. high. On its seaward face Cape Wrath (a corruption of the Icelandic *hvarf*, turning-point) rises in precipitous cliffs to a height of 300 ft. The gneiss rocks are scored with pink granite. Sunken reefs keep the sea almost always in tumult. Of the larger islands Handa, usually visited from Scourie on the west coast, has magnificent cliff scenery, distinguished for its beautiful coloration, its caverns and the richness and variety of the bird life, especially on the north-west, where the Torridonian sandstone rocks are 406 ft. high. The cave of Smoo (Icelandic *smuga*, hole: same root as smuggle) on the north coast, 1 m. east of Durness, is the most famous cavern in the shire; it consists of three chambers hollowed out of the limestone; the entrance hall, 33 ft. high and 203 ft. long, is separated from the inner chamber, 70 ft. long by 30 ft. wide, by a ledge of rock beneath which pours a stream that descends as a cataract from a hole in the roof, 80 ft. above. Behind the waterfall is the third chamber, 120 ft. long by 8 ft. wide, which can only be seen by artificial light.

Geology.—A very irregular line from Loch Eriboll on the north coast to the neighbourhood of Cromalt near the southern boundary separates the two rock groups that form the foundation of the major portion of the county. On the western side of this line are the ancient gneisses and schists (the Lewisian gneiss); these are penetrated by innumerable basic and acid dikes which generally have a north-west to south-east trend. On the eastern side of the line, occupying the whole of the remaining area except the eastern fringe of the county, is a younger series of metamorphic rocks, the Moine schists. Resting with marked unconformability upon the old gneiss near Cape Wrath, at Ru Stoer, Quinag, Canisp and Suilven are the dark red conglomerates, breccias and sandstones of Torridonian age. Cambrian rocks succeed the Torridonian, again with strong unconformity; they are represented in ascending order by (1) false bedded quartzite, (2) quartzite with annelid burrows, the "pipe rock," (3) the fucoid beds with *Olenellus* band, (4) serpulite grit, (5) Durness limestone and dolomite and their marmorized equivalents. The white quartzite that has been left as a cap on such dark Torridonian hills as Quinag and Canisp forms a striking feature in the landscape. These Cambrian rocks occupy a very irregular belt along the line above mentioned; the broadest tract is in the neighbourhood of Loch Assynt, another large area lies about the southern end of Loch Eriboll and the Durness limestone is extensively developed near the loch of that name. Along the belt of Cambrian rocks there is abundant evidence of crustal deformation on the most extensive scale; one after another great slices of rock, often miles in extent, have been sheared off and pushed forward by thrusts from a south-easterly direction, so that in several places it is possible to find the Lewisian gneiss dragged up and carried forward right on to the Cambrian; in the Durness district the eastern schists have been so transported from a distance of 10 m. The most striking of the planes of thrusting is that known as the Moine, others of great magnitude occur to the west of it, such as those by Glencoul and Ben More. Masses of granite appear in the eastern schists on the county boundary by Strath Halladale, at Ben Laoghal, Ben Stomino and east of Lairg. The Old Red Sandstone forms some elevated ground around Dornoch and Golspie and patches occur at Portskerra and elsewhere. A narrow strip of Mesozoic strata lies along the coast from Golspie Burn to Ord. Triassic marls are seen in the Golspie stream; these are succeeded northwards, near Dunrobin Castle, by Lias, then by Great Oolite, with the Brora coal, followed by Oxfordian, Corallian and Kimeridgian beds. Evidence of ice action is everywhere apparent, the striations show that the ice travelled towards the north-west and north, and from the eastern part of the county, towards Moray Firth.

Climate and Agriculture.—The rainfall varies greatly, being lowest on the south-east and highest in the mountainous hinterland of the west, with an annual mean of 44·7 in. The average temperature for the year is 47° F., for January 38·5° F., for July 56·5° F. Only one-fortieth of the total area is under cultivation, the shire ranking lowest in Scotland in this respect. The great mass of the surface is grazing ground and deer forest. The best land adjoins Dornoch Firth, where farming is in an advanced condition, but there are fertile patches along the river valleys. At the beginning of the 19th century the crofters occupied almost every cultivable spot, and were more numerous than the soil could support. The first duke of Sutherland (then marquis of Stafford) adopted a policy of wholesale clearance. Between 1811 and 1820 fifteen thousand peasants were evicted from their holdings in the interior and transferred to the coast. The duke incurred great obloquy, but persisted in his reforms, which included reduction of rent, improvement in the well-being of the people, reclamation of thousands of acres, and abolition of the tacksman or middleman, so that tenants should hold directly of himself. He also did much to open up the shire generally. Between 1812—when there was only one bridge and no road in Sutherland—and 1832, he bore half the cost, the government contributing the rest, of constructing 450 m. of road, 134 bridges, some of considerable size, and the iron bridge at Bonar of 150 ft. span. The 3rd duke (1828–1892) carried out a large plan of reclamation. Attempts have been made to repeople some of the glens (Strathnaver, for example) depopulated by the clearances. Crofters still largely predominate, nearly two-thirds of the holdings being under 5 acres—the highest proportion in Scotland. The chief grain crops are oats and barley, the chief green crops turnips (including swedes) and potatoes. The raising of livestock is the staple business of the county. The sheep are mostly Cheviots, the cattle West Highland, shorthorn and crossbred. Horses—principally ponies, though Clydesdales are used on the bigger farms—are almost wholly kept for agricultural purposes, and pigs are also reared. The deer forests belonging to the duke of Sutherland are Reay, 64,600 acres; Ben Armine and Coirna-fearn, 35,840; Glen Canisp, 34,490; and Dunrobin, 12,180—in all 147,110 acres, or more than one-ninth of the whole area. Excepting the south-east coast, the valley of the Shin, and a considerable portion of Strath Oykell, there are very few districts under wood.

Other Industries.—Next to agriculture, the deep-sea fishery and the salmon fisheries in the rivers are the most important interest. Helmsdale (pop. 1259) is the only port of any consequence. Herrings are the principal catch, but cod, ling and other fishes are also taken. Whisky is distilled at Clyne and Brora; some woollens are manufactured at Rogart; coal is mined at Brora, marble quarried in Assynt and limestone and sandstone in several districts. The exceptional facilities offered by the deer forests, moors and the many lochs and rivers attract large numbers of sportsmen whose custom is valuable to the inhabitants; and Dornoch and Lochinver are in growing repute as holiday resorts. The Highland railway enters the county at Invershin, goes northward to Lairg, then east to Brora and north-east to Helmsdale, whence it runs north-west to Kildonan, and north to Forsinard, where it shortly afterwards leaves the shire. The Glasgow steamers call at Lochinver once a week, and mail-cars run periodically from Lairg to Lochinver and Scourie in the west and to Durness and Tongue in the north; from Helmsdale, by the coast, to Berriedale, Dunbeath, Latheron and Lybster; and from Tongue to Thurso. Considering its scanty and scattered population and mountainous character, the county is well intersected by roads, many of which were constructed by successive dukes of Sutherland, who own four-fifths of the shire.

Population and Administration.—In 1891 the population amounted to 21,896, and in 1901 it was 21,440, or 11 persons to the square mile, the least populous of Scottish counties. Several islands lie off the west and north coast, but only Roan, at the entrance to Kyle of Tongue, is inhabited (67). In 1901 there were 469 persons speaking Gaelic only, 14,083 who spoke Gaelic and English. The county returns a member to parliament, and Dornoch, the county town, belongs to the Wick group of parliamentary burghs. Sutherland forms a joint sheriffdom with Ross and Cromarty, and a sheriff-substitute presides at Dornoch. The county is under school-board jurisdiction; some of the schools earn the grant for higher education, and the "residue" grant is expended in bursaries. The Sutherland combination poorhouse is situated in Creich and there is a hospital, the Lawson Memorial, in Golspie.

History and Antiquities.—Of the Picts, the original inhabitants, there are considerable remains in the form of *brochs* (or round towers), numerous and widely scattered, Picts' houses, tumuli, cairns and hut circles. Dun Dornadilla, in the parish of Durness, 4 m. south of Loch Hope, is a tower, 150 ft. in circumference, still in good preservation. The Norse jarl Thorfinn overran the country in 1034 and the Scandinavian colonists called it, in relation to their settlements in the Orkneys and Shetlands, *Sudrland*, the "southern land," or Sutherland. After the conquest of the district by the Scottish kings, Sutherland was conferred on Hugh Freskin (a descendant of Freskin of Moravia or Moray), whose son William was created earl of Sutherland in 1228 by Alexander II. Assynt was peopled by a branch of the Macleods of Lewis, till they were dispossessed by the Mackenzies, who sold the territory to the earl of Sutherland about the middle of the 18th century. The vast tract of the Reay country, belonging to the Mackays, an ancient clan, also fell piece by piece into the hands of the Sutherland family. Killin, on the east bank of Loch Brora, was the site of an old chapel dedicated to St Columba, an association commemorated in the name of Kilcolmkill House, hard by. On the south shore of Helmsdale creek stand the ruins of the castle in which the 11th earl of Sutherland and his wife were poisoned by his uncle's widow in 1567, with a view to securing the title for her only child who was next of kin to the earl and his son. Ardvreck Castle, now in ruins, at the east end of Loch Assynt, was the prison of the marquis of Montrose after his defeat at Invercarron (1650), whence he was delivered up by Neil Macleod of Assynt for execution at Edinburgh. In the graveyard of the old church of Durness is a monument to Robert Mackay, called Rob Donn (the brown), the Gaelic poet (1714–1778).

St John, *Tour in Sutherlandshire* (1849); Hugh Miller, *Sutherland as it was and is* (1843); D. W. Kemp, *Bishop Pococke's Tour in 1760 in Sutherland and Caithness* (1888); Sir W. Fraser, *The Sutherland Book* (1893); A. Gunn and S. J. Mackay, *Sutherland and the Reay Country* (1897).

SUTLEJ, a river of India, one of the "Five Rivers" of the Punjab. It rises E.S.E. of the Manasarowar lakes in Tibet, at an elevation of about 15,200 ft., threads its way through the gorges of the Himalayas with heights of 20,000 ft. on either side, crosses Bashahr and the Simla hill states, and enters the British district of Hoshiarpur. Thence it flows through the plains of the Punjab, receives the Beas in Kapurthala state, and joins the Chenab near Madwala. From that point the whole river bears the name of Panjnad ("five rivers") until it falls into the Indus near Mithankot after a course of 900 m. In the time of Ranjit Singh the Sutlej formed the boundary line between the Sikh and British dominions, and the Sikh states south of the river still bear the title of Cis-Sutlej.

The Sutlej supplies two systems of irrigation works: the Sirhind canal, which draws off the whole of the cold season supply of the Sutlej at Rupar, 100 m. above its junction with the

Beas; and the inundation canals of the Upper and Lower Sutlej, Ferozepur and Bahawalpur, which come below the junction.

SUTLER, a camp-follower who sells provisions, liquor and other things to an army in the field, in camp or in quarters. The word was one of the numerous naval and military terms adapted in English from the Dutch, where it appears as *soetelaar* or *zoetelaar*. It meant originally one who does dirty work, a drudge, a scullion, and is derived from *zoetelen*, to foul, sully, a word cognate with "suds," hot soapy water, "seethe," to boil, and "sodden."

SUTRI (anc. *Sutrium*), a town and episcopal see of Italy, in the province of Rome, 4 m. W.N.W. of the railway station of Capranica, which is 36 m. from Rome; 955 ft. above sea-level. Pop. (1901), 2701. The town is picturesquely situated on a narrow hill, surrounded by ravines, a narrow neck on the west alone connecting it with the surrounding country. There are some remains of the ancient city walls of rectangular blocks of tufa on the southern side of the town, and some rock-cut sewers in the cliffs below them. The cathedral is modern, but the crypt, with twenty columns, is old, and the campanile dates from the 13th century. In the cliffs opposite the town on the south is the rock-cut church of the Madonna del Parto, developed, no doubt, out of an Etruscan tomb, of which there are many here; and close by is a rock-hewn amphitheatre of the Roman period, with axes of 55 and 44 yds., now most picturesque.

The position of Sutri was important, commanding as it did the road into Etruria, the later Via Cassia; and it is spoken of by Livy as one of the keys of Etruria, Nepet being the other. It came into the hands of Rome after the fall of Veii, and a Latin colony was founded there; it was lost again in 386, but was recovered and recolonized in 383 (?). It was besieged by the Etruscans in 311–10 B.C., but not taken. With Nepet and ten other Latin colonies it refused further help in the Hannibalic War in 209 B.C. Its importance as a fortress explains, according to Festus, the proverb *Sutrium ire*, of one who goes on important business, as it occurs in Plautus. It is mentioned in the war of 41 B.C., and received a colony of veterans under the triumviri (*Colonia coniuncta Iulia Sutrina*). Inscriptions show that it was a place of some importance under the empire, and it is mentioned as occupied by the Lombards.

See G. Dennis, *Cities and Cemeteries of Etruria*, i. 62 (London, 1883). (T. As.)

SUTTEE (an English corruption of Sanskrit *sati*, "good woman" or true "wife"), the rite of widow-sacrifice, *i.e.* the burning the living widow on the funeral pyre of her husband, as practised among certain Hindu castes. As early as the *Atharva Veda* the rite is mentioned as an "old custom," but European scholars have shown that the text of the still earlier *Rig Veda* had been corrupted, probably wilfully, by the Hindu priesthood, and that there was no injunction that the rite should be observed. The directions of the *Rig Veda* seem to have involved a merely symbolic suttee: the widow taking her place on the funeral pile, but being recalled to "this world of life" at the last moment by her brother-in-law or adopted child. The practice was sporadically observed in India when the Macedonians reached India late in the 4th century B.C. (Diod. Sic. xix. 33–34); but the earlier Indian law books do not enjoin it, and Manu simply commands the widow to lead a life of chastity and asceticism. About the 6th century A.D. a recrudescence of the rite took place, and with the help of corrupted Vedic texts it soon grew to have a full religious sanction. But even so it was not general throughout India. It was rare in the Punjab; and in Malabar, the most primitive part of southern India, it was forbidden. In its medieval form it was essentially a Brahminic rite, and it was where Brahminism was strongest, in Bengal and along the Ganges valley and in Oudh and Rajputana, that it was most usual.

The manner of the sacrifice differed according to the district. In south India the widow jumped or was forced into the fire-pit; in western India she was placed in a grass hut, supporting the corpse's head with her right hand while her left held the torch; in the Ganges valley she lay down upon the already lighted pile; while in Nepal she was placed beside the corpse, and when the pile was lighted the two bodies were held in place by long poles pressed down by relatives. The earliest attempt to stop suttee was made by Akbar (1542–1605), who forbade compulsion, voluntary suttees alone being permitted. Towards the end of the 18th century the British authorities, on the initiative of Sir C. Malet and Jonathan Duncan in Bombay, took up the question, but nothing definite was ventured on till 1829 when Lord William Bentinck, despite fierce opposition, carried in council on the 4th of December a regulation which declared that all who abetted suttee were "guilty of culpable homicide." Though thus illegal, widow-burning continued into modern days in isolated parts of India. In 1905 those who assisted at a suttee in Behar were sentenced to penal servitude.

Widow sacrifice is not peculiar to India, and E. B. Tylor in his *Primitive Culture* (ch. 11) has collected evidence to support a theory that the rite existed among all primitive Aryan nations. He thinks that in enjoining it the medieval priesthood of India were making no innovation, but were simply reviving an Aryan custom of a barbaric period long antedating the Vedas. See also Jakob Grimm, *Verbrennen der Leichen.*

SUTTNER, BERTHA, BARONESS VON (1843–), Austrian writer, was born at Prague on the 9th of July 1843, the daughter of Count Franz Kinsky, Austrian field marshal, who died shortly after her birth. On her mother's side she was descended from the family of the German poet, Theodor Körner. After receiving a careful education she travelled abroad and resided for a long period in Paris and in Italy. In 1876 she married the novelist, Freiherr Arthur Gundaccar von Suttner (1850–1902), and for the next nine years lived with him at Tiflis in the Caucasus. After 1885 she resided at Schloss Harmansdorf, near Eggenburg, in Lower Austria. The Baroness von Suttner, a fertile writer, has produced numerous tales, books on social science and romances, among which the best known are *Inventarium einer Seele* (1882), *Die Waffen nieder* (1889), *Hanna* (1894), *La Traviata* (1898), *Schach der Qual* (1898), *Martha's Kinder* (1903), a continuation of *Die Waffen nieder*. She was at one time secretary to Alfred Nobel, and as a champion of the "brotherhood of nations," had much influence on him and others; and in this connexion has published *Krieg und Frieden* (1896), *Das Maschinen-Zeitalter*, *Zukunfts-Vorlesungen über unsere Zeit* (1899) and *Die Haager Friedenskonferenz* (1900). In 1905 she was awarded a Nobel prize of £5000 for her endeavours in the cause of peace.

Her *Memoiren*, full of interesting autobiographical matter, were published at Stuttgart in 1908.

SUTTON, SIR RICHARD (d. *c.* 1524), the founder, with William Smyth, bishop of Lincoln, of Brasenose College, Oxford, and the first lay founder of any college, is said to have come of a good north-country family, the Suttons of that ilk, near Macclesfield, Cheshire. Little is known of his life, but he was a barrister, and in 1497 a member of the privy council. In 1513 he became steward of the monastery of Sion, a house of Brigittine nuns at Isleworth. How Smyth and Sutton came to plan a college is not known, but in 1508 we find Edmund Croston, or Crofton, bequeathing £6, 13s. 4d. towards the building of "a college of Brasynnose" if the projects of "the bishop of Lincoln and master Sotton" were carried into effect within a stipulated period. In the same year Sutton obtained a ninety-two year lease of Brasenose Hall and Little University Hall for £3 per annum, and from that time until the end of his life was occupied in purchasing estates with which he might endow the new college. He is thought to have contributed to the funds of Corpus Christi College, Oxford, as well. He was knighted some years before his death, which occurred about 1524.

SUTTON, THOMAS (*c.* 1532–1611), founder of Charterhouse school and hospital, was the son of an official of the city of Lincoln, and was educated at Eton College and probably at Cambridge. He then spent some time travelling in Europe and appears to have acted as secretary to two or three English noblemen. He became a soldier, and in 1569 was with the troops engaged in suppressing the rising in the north of England; in 1570 he was made master and surveyor of the ordnance in the northern parts of the realm and in this capacity he took part in the siege of Edinburgh Castle by the English in May 1573. Sutton obtained great wealth by the ownership of coal mines in Durham and also by his marriage in 1582 with Elizabeth (d. 1602), widow of John Dudley of Stoke Newington. His wish to devote some of his money to charitable purposes led him in 1611 to purchase for £13,000 the Charterhouse (*q.v.*) from Thomas Howard, earl of Suffolk. On this spot Sutton erected the hospital and school which he had originally intended to build at Hallingbury in Essex. Sutton died at Hackney on the 12th of December 1611 and was buried in the chapel in the Charterhouse. His wealth was left for charitable uses, but in 1613 James I. ordered his executors to make an allowance to his natural son, Roger Sutton.

SUTTON, an urban district in the Epsom parliamentary division of Surrey, England, 11 m. S. of London by the London Brighton & South Coast railway. Pop. (1891), 13,977; (1901), 17,223. It is pleasantly situated at the edge of the Downs, and is in favour as an outer residential district of London. The manor, according to Domesday, belonged to the abbey of Chertsey at the Conquest and continued so until the dissolution of the monasteries by Henry VIII.

SUTTON COLDFIELD, a municipal borough in the Tamworth parliamentary division of Warwickshire, England, 7 m. N.E. from Birmingham on branches of the London & North-Western and Midland railways. Pop. (1901), 14,264. The town, which lies high in a hilly situation, is the centre of a residential district for persons having their business offices in Birmingham, Walsall and other towns. The church of the Holy Trinity, Early English and Late Perpendicular, enlarged in 1879, contains a fine Norman font and the tomb of Bishop Vesey. On the picturesque park near the town, 2400 acres in extent, the inhabitants have the right of grazing horses and cattle at a small fee. This, with the Crystal Palace gardens, forms a recreation ground for the people of Birmingham. In the vicinity are New Hall, an interesting mansion of the 13th century, with a hall of the 16th, used as a boys' school; and Peddimore Hall, a moated mansion of the ancient family of Arden, of which there are slight remains. The town is governed by a mayor, 6 aldermen and 18 councillors. Area, 12,828 acres.

Sutton Coldfield (*Svtone, Sutton in Colefeud, Sutton Colfild, King's Sutton*) is mentioned in the Domesday Survey as a possession of the Conqueror and as having been held before that time by Edwin, earl of Mercia. Henry I. exchanged it with Roger de Newburgh, earl of Warwick, whose descendant, William de Beauchamp, in the reign of Edward I., claimed by prescription a court leet with assize of bread and ale and other liberties here, which were allowed him, as it was found that his ancestors had held the same. By the time of Henry VIII. the town had fallen "into much ruin," according to Leland, and would never have reached its present position but for the interest of John Vesey, bishop of Exeter, a native of the place, who procured for it a charter of incorporation in 1529 under the title of the "Warden and Society of the Royal Town of Sutton Coldfield." The charter also appointed a warden and twenty-two fellows to be the common hall, and granted the town and park to the corporation at a yearly rent of £58. Another charter, dated 1664, appointed two capital burgesses to be justices of the peace with the warden. In 1855 Sutton was divided into six wards, with an alderman and three councillors for each. Markets granted in 1300, 1353 and 1529 have been discontinued. Fairs were granted in 1300, 1353 and 1529, to be held at the feasts of Trinity, Michaelmas and St Simon and St Jude, and are now held on Trinity Monday, the 14th of March, the 19th of September and the 8th of November. Vesey set up here a cloth trade which, however, soon became neglected.

SUTTON-IN-ASHFIELD, an urban district in the Mansfield parliamentary division of Nottinghamshire, England, lying in a picturesque district on the border of Sherwood Forest, on branch lines of the Midland and Great Northern railways, 15 m. N. by W. of Nottingham. Pop. (1891), 10,562; (1901), 14,862. The church of St Mary Magdalene of the 12th and 14th centuries was restored in 1868. There are collieries and limeworks in the vicinity. Cotton hosiery and thread are the principal manufactures.

SUVÁROV. ALEXANDER VASILIEVICH, COUNT SUVÁROV RIMNIKSKY, PRINCE ITALYSKY (1729–1800), Russian field marshal, was born at Moscow on the 24th of November 1729, the descendant of a Swede named Suvor who emigrated to Russia in 1622. He entered the army as a boy, served against the Swedes in Finland and against the Prussians during the Seven Years' War. After repeatedly distinguishing himself in battle he was made a colonel in 1762. He next served in Poland, dispersed the Polish forces under Pulawski, stormed Cracow (1768) and was made a major-general. In his first campaigns against the Turks in 1773–74, and particularly in the battle of Kosludscki in the latter year, he laid the foundations of his reputation. In 1775 he suppressed the rebellion of Pugachev, who was decapitated at Moscow. From 1777–1783 he served in the Crimea and the Caucasus, becoming a lieutenant-general in 1780, and general of infantry in 1783, on the conclusion of his work there. From 1787 to 1791 he was again fighting the Turks and won many victories; he was wounded at Kinburn (1787), took part in the siege of Ochakov, and in 1788 won two great victories at Focsani and on the Rimnik. For the latter victory, in which an Austrian corps under Prince Josias of Saxe-Coburg participated, Catherine II. made him a count with the name Rimniksky in addition to his own name, and the emperor Joseph II. created him a count of the Holy Roman Empire. On the 22nd of December 1790 Suvárov stormed Ismail in Bessarabia, and the sack and the massacre that followed the capture equals in horror such events as the "Spanish Fury" and the fall of Magdeburg. He was next placed at the head of the army which subdued the Poles, and repeated the triumph, and some of the cruelties, of Ismail at Warsaw. He was now made a field marshal, and was retained in Poland till 1795, when he returned to St Petersburg. But his sovereign and friend Catherine died in 1796, and her successor Paul dismissed the veteran in disgrace. Suvárov then lived for some years in retirement on his estate of Konchauskoy, near Moscow. He criticized the new military tactics and dress introduced by the emperor, and some of his caustic verse reached the ears of Paul. His conduct was therefore watched and his correspondence with his wife, who had remained at Moscow—for his marriage relations had not been happy—was tampered with. On Sundays he tolled the bell for church and sang among the rustics in the village choir. On week days he worked among them in a smock frock. But in February 1799 he was summoned by the tsar to take the field again, this time against the French Revolutionary armies in Italy.

The campaign (see FRENCH REVOLUTIONARY WARS) opened with a series of victories (Cassano, Trebbia, Novi) which reduced the French government to desperate straits and drove every French soldier from Italy, save for the handful under Moreau, which maintained a foothold in the Maritime Alps and around Genoa. Suvárov himself was made a prince. But the later events of the eventful year went uniformly against the allies. Suvárov's lieutenant Korsákov was defeated by Masséna at Zürich, and the old field marshal, seeking to make his way over the Swiss passes to the Upper Rhine, had to retreat to the Vorarlberg, where the army, much shattered and almost destitute of horses and artillery, went into winter quarters. Early in 1800 Suvárov returned to St Petersburg in disgrace. Paul refused to give him an audience, and, worn out and ill, he died a few days afterwards on the 18th of May 1800 at St Petersburg. Lord Whitworth, the English ambassador, was the only person of distinction present at the funeral. Suvárov lies buried in the church of the Annunciation in the Alexandro-Nevskii monastery, the simple inscription on his grave being, according to his own direction, "Here lies Suvárov." But within a year of his death the tsar Alexander I. erected a statue to his memory in the Field of Mars, St Petersburg.

His son Arkadi (1783–1811) was a general officer in the

Russian army during the Napoleonic and Turkish wars of the early 19th century, and was drowned in the river Rimnik in 1811. His grandson Alexander Arkadievich (1804–1882) was also a Russian general.

Among the Russians the memory of Suvárov is cherished to this day. A great captain, viewed from the standpoint of any age of military history, he is specially the great captain of the Russian nation, for the character of his leadership responded to the character of the Russian soldier. In an age when war had become an act of diplomacy he restored its true significance as an act of force. He was reckless of human life, bent only on the achievement of the object in hand, and he spared his own soldiers as little as he showed mercy to the population of a fallen city. He was a man of great simplicity of manners, and while on a campaign lived as a private soldier, sleeping on straw and contenting himself with the humblest fare. But he had himself passed through all the gradations of military service; moreover, his education had been of the rudest kind. His gibes procured him many enemies. He had all the contempt of a man of ability and action for ignorant favourites and ornamental carpet-knights. But his drolleries served, sometimes to hide, more often to express, a soldierly genius, the effect of which the Russian army has not outgrown. If the tactics of the Russians in the war of 1904–05 reflected too literally some of the maxims of Suvárov's Turkish wars, the spirit of self-sacrifice, resolution and indifference to losses there shown was a precious legacy from those wars. Dragomirov (*q.v.*) avowed that his teaching was based on Suvárov's practice, which he held to be representative of the fundamental truths of war and of the military qualities of the Russian nation.

See Anthing, *Versuch einer Kriegsgeschichte des Grafen Suworow* (Gotha, 1796–1799); F. von Smitt, *Suworows Leben und Heerzüge* (Vilna, 1833–1834) and *Suworow und Polens Untergang* (Leipzig, 1858); Von Reding-Biberegg, *Der Zug Suworows durch die Schweiz* (Zürich, 1896); Lieut.-Colonel Spalding, *Suvórof* (London, 1890); G. von Fuchs, *Suworows Korrespondenz, 1799* (Glogau, 1835); *Souvorov en Italie*, by Gachot, Masséna's biographer (Paris, 1903); and the standard Russian biographies of Polevoi (1853; Ger. trans., Mitau, 1853); Rybkin (Moscow, 1874) and Vasiliev (Vilna, 1899).

SUWALKI, a government of Russian Poland, of which it occupies the N.E. corner, extending to the N. between East Prussia and the Russian governments of Vilna and Grodno, with the government of Kovno on the N. Its area is 4846 sq. m. It includes the east of the low Baltic swelling (800 to 1000 ft. above the sea) and is studded with lakes. Its northern slopes descend to the valley of the Niemen, while in the south it falls away gently to the marshy tract of the Biebrz. The rivers flow there in deep-cut gorges and hollows, diversifying the surface. The Niemen forms its eastern and northern boundary and has many affluents from both slopes of the swelling. The Augustowo canal connects the navigable Hancza, a tributary of the Niemen, with a tributary of the Biebrz, which belongs to the basin of the Vistula, and an active traffic is carried on by this canal. Forests cover about one-fourth of the area. Tertiary and cretaceous strata occupy large areas, and the entire surface is covered with Post-Tertiary deposits. The bottom moraine of the great ice-sheet of north Germany, containing scratched boulders and furrowed by depressions having a direction N.N.E. and S.S.W., extended over immense tracts of the ridge of the lake-districts and its slopes, while limited spaces are covered with well-washed glacial sands and gravel. On the northern slopes of the coast-ridge, the boulder-clay being covered with lacustrine deposits, there are in many places areas of fertile soil; and in the southern parts of the province the boulder-clay is stony, and sometimes covered with gravel. Still, nearly nine-tenths of the surface are suitable for cultivation.

The population in 1906 was estimated at 633,900. The majority (52·2%) are Lithuanians, mostly in the north; there are 21·5% Poles (and Mazurs), chiefly in the towns; 16·7% Jews; 5·3% Germans and 4·2% Russians. The chief towns of the seven districts into which the government is divided are Suwalki, Augustowo, Kalwarya, Mariampol, Seiny, Wilkowiszki (or Volkovyshki) and Wladislawow. The principal crops are rye, wheat, oats, barley and potatoes, which are largely exported to Prussia for use in the distilleries. Bee-keeping is widely spread, and about 40,000 ℔ of honey are obtained every year. The weaving of linen, woollen cloth and fishing-nets is extensively carried on in the villages as a domestic industry, and in small factories. A large number of the inhabitants are compelled to seek work in winter in other parts of the empire. The felling of timber, which is floated down the Niemen, gives occupation to many.

SUWALKI, a town of Russian Poland, capital of the government of the same name, situated at the source of the Hancza, a tributary of the Niemen, 65 m. by rail N.W. of Grodno. Pop. 27,165. In the 15th century it was a small village amid forests, peopled by Lithuanians. Its trade is chiefly in timber, grain, woollen cloth and other manufactured goods.

SUYŪṬĪ [Abū-l Fadhl'Abd ur-Rahmān ibn Abī Bakr Jalāl ud-Dīn us-Suyūṭī] (1445–1505), Arabian encyclopaedic writer, was the son of a Turkish slave woman. His father, who was of Persian descent, had been cadi in Suyūṭ (Upper Egypt) and professor in Cairo, but died before his son was six years old. The boy's training was taken in hand by a Sufi friend of the father. He was precocious and is said to have known the Koran by heart before he was eight years old. In 1462 he was already a teacher; in 1464 he made the pilgrimage to Mecca; in 1472 he became a professor, and in 1486 was promoted to a chair in the mosque of Bibars. Here, however, he provoked a revolt among the students and in 1501 was discharged for maladministration of trust funds. Two years later he was offered the same post again, but declined, and worked in seclusion at Rauḍa, an island of the Nile, and there died in 1505. He was one of the most prolific writers of the East, though many of his works are only pamphlets and some are mere abridgments of the work of others.

We know of 561 separate titles of his works, and over 316 exist in manuscript. A list of these is given in C. Brockelmann's *Gesch. der Arabischen Litteratur*, ii. 144–158 (Berlin, 1902). They deal with almost every branch of Moslem science and literature. Among the best known are the *Itqān fi 'Ulūm ul-Qurān* (on the exegetic sciences of the Koran), published with an analysis by A. Sprenger (Calcutta, 1852–1854) and often in Cairo; the commentary on the Koran, known as the *Tafsīr ul-Jalalain*, begun by Jalāl ud-Dīn ul-Maḥalli (1389–1459) and finished by Suyūṭī, published often in the East; and the history of the caliphs, published at Calcutta (1858) and elsewhere. (G. W. T.)

SUZERAINTY. "Suzerain," a term of feudal law, is now used to describe persons or states in positions of superiority to others. Its etymology, according to Professor W. W. Skeat (*Etymological Dictionary*), is as follows: "A coined word; made from French *sus*, Latin *susum* or *sursum*, above, in the same way as sovereign is made from Latin *super*; it corresponds to a Low Latin type *suseranus*." Another form of the word is souseran (F. Godefroy, *De l'Ancienne langue française*). Suzerain has been defined as "Qui possède un fief dont d'autres fiefs relèvent" (*Littré* and *Dictionnaire de l'académie française*). C. Loyseau, in his *Traité des seigneuries* (3rd ed., 1610, p. 14), explains that there are two kinds of public seigneuries, that is, sovereign seigneurs, possessing *summum imperium*, and suzerains, "Les suzeraines sont celles qui ont puissance supérieure mais non suprême." Elsewhere he says that suzerainty is a form of public seigneuries which has been "usurpée par les particuliers pour laquelle exprimer il nous a fallu forger un mot exprés, et l'appeller suzeraineté, mot qui est aussi étrange comme celle espèce de seigneuries est absurde" (p. 11). Loyseau adds, "Seigneurie suzeraine est dignité d'un fief ayant justice" (p. 38). Bousquet (*Nouveau dictionnaire de droit*) defines suzerain as "supérieur, celui dont un fief relevait"; Rogulau (*Glossaire du droit françois*), "supérieur en quelque charge ou dignité autre que le roy." The name does not occur in the *Consuetudines feudorum*, or in Hotoman's *De verbis feudalibus commentarius*. It was rare in feudal times in England. But it was used in France to describe a feudal lord, the supreme suzerain being the king. Merlin, under *suzeraineté*, shows that the word was not used by all feudal writers in the same sense. (See also Chas. Butler's note to *Coke on Litt.* 191 *a.*)

Definition.

In modern times the term has come to be used as descriptive of relations, ill-defined and vague, which exist between powerful and dependent states; its very indefiniteness being its recommendation. According to feudal law the vassal owed certain duties to the lord; he promised fidelity and service; and the lord was bound to perform reciprocal duties, not very

Modern Usage.

clearly defined, to the vassal—*Dominus vassallo conjux et amicus dicitur.* The relation between a lord and his vassals, implied in the oath of fealty, has been extended to states of unequal power; it has been found convenient to designate certain states as vassal states, and their superiors as suzerains. Originally and properly applicable to a status recognized by feudalism, the term vassal state has been used to describe the subordinate position of certain states once parts of the Ottoman Empire, and still loosely connected therewith. Such are Egypt and Bulgaria. Rumania, Servia and Montenegro, once vassal states, may now be regarded as independent. The relations of these states to the Ottoman Porte are very varied. Egypt has been variously described as a vassal state or as a protectorate. But all of these pay tribute to the sultan, or in some way acknowledge his supremacy (Emanuel Ullmann, *Völkerrecht*, § 16); M. de Martens (*Traité de droit international*, 1883, i. 333 n.) thus defines the term: "La suzeraineté est la souveraineté limitée exercée par le pouvoir suprême d'un état sur un gouvernment mi-souverain," a definition applicable to protectorates, with which it is often confounded. Thus Mommsen (*History of Rome*) indiscriminately describes the supremacy of Rome over Armenia as "suzerainty" or "protectorate." To illustrate the vague use of the word in modern diplomacy may be quoted the description of suzerainty given by Lord Kimberley, which Mr Chamberlain in the correspondence as to South Africa mentioned with approval: "Superiority over a state possessing independent rights of government subject to reservations with reference to certain specified matters" (1899 [C. 9057], p. 28).

Protectorate and Suzerainty.

M. Gairal (*Le Protectorat international*) distinguishes suzerainty from protectorate in these respects: (*a*) suzerainty proceeds from a concession on the part of the suzerain (p. 112); (*b*) the vassal state is bound to perform specific services; and (*c*) the vassal state has larger powers of action than those belonging to a protected state; (*d*) there is reciprocity of obligation. According to M. F. Despagnet the term suzerain is applicable to a case in which a state concedes a fief, in virtue of its sovereignty (*Essai sur le protectorat international*, p. 46), reserving to itself certain rights as the author of this concession.

Another writer draws these distinctions: (*a*) a state connected by protectorship with another previously enjoyed autonomy; the vassal state did not; (*b*) the protected state retains its nationality and its internal administration; the vassal state acquires a distinct nationality; (*c*) the establishment of a protectorate modifies few of the institutions of the protectorate state except as to foreign relations; the establishment of a suzerainty changes the institutions of the vassal state; (*d*) the protected state exercises its internal sovereignty *à peu près pleinement*; the vassal state remains subordinate in several respects; (*e*) while the protected state has the right to be assisted in case of war by the protecting state, but is not bound to defend the latter, the vassal state is bound to aid its suzerain (Tchomacoff, *De la Souveraineté*, p. 53). See also Hachenburger, *De la Nature juridique du protectorat.*

W. E. Hall thus defines vassal states: "States under the suzerainty of others are portions of the latter which during a process of gradual disruption or by the grace of the sovereign have acquired certain of the powers of an independent community, such as that of making commercial conventions, or of conferring their exequatur on foreign consuls. Their position differs from that of the foregoing varieties of states (protectorates, &c.), in that a presumption exists against the possession by them of any given international capacity (*International Law*, 4th ed., p. 31).

Another suggested distinction is this: Suzerainty is title without corresponding power; protectorate is power without corresponding title (Professor Freund, *Political Science Quarterly*, 1899, p. 28).

On the whole, usage seems to favour this distinction: while a protectorate flows from, or is a reduction of, the sovereignty of the protected state, suzerainty is conceived as derived from, and a reduction of, the sovereignty of the dominant state.

As to the power of making treaties, a vassal state cannot, as a rule, conclude them; such power does not exist unless it is specially given. On the other hand, a protected state, unless the contrary is stipulated, retains the power of concluding treaties (Bry, p. 294).

It is sometimes said that a protected state, unlike a vassal state, has the right of sending representatives to foreign states. But such distinctions are of doubtful value: the facts of each case must be considered (Ullmann, § 26).

There is one practical difference between the two relations: while the protecting and protected states tend to draw nearer, the reverse is true of the suzerain and vassal states; a protectorate is generally the preliminary to incorporation, suzerainty to separation. Sometimes it is said that the territory of the vassal state forms part of the territory of the suzerain; a proposition which is true for some purposes, but not for all.

Instances of Suzerainty.

All definitions of suzerainty are of little use. Each instrument in which the word is used must be studied in order to ascertain its significance. Even in feudal times suzerainty might be merely nominal, an instance in point being the suzerainty or over-lordship of the papacy over Naples. In some cases it may be said that suzerainty brings no practical advantages and implies no serious obligations. Among the instances in which the term is actually used in treaties are these: the General Treaty, Peace of Paris, 1856 (arts. 21 and 22), recognized the suzerainty of Turkey over the Danubian principalities Moldavia and Wallachia, modifying the "sovereignty" of Turkey recognized by the Treaty of Adrianople. "Les principautés de Valachie et de Moldavia continueront à jouir, sous la suzeraineté de la Porte et sous la garantie des Puissances contractantes, des privilèges et des immunités dont elles sont en possession." The convention of the 19th of August 1858 (Hertslet x. 1052) organized the then principalities "under the suzerainty of the sultan" (art. 1). The internal government was to be exercised by a hospodar, who received his investiture from the sultan, the sign of vassalship, it has been said (Tchomacoff p. 45). The autonomy of these vassal states has been fully recognized by the Treaty of Berlin of 1878 (art. 1). In the Interpretation Act, 1889, s. 18 (5), "suzerainty" is used to describe the authority of the sovereign over native princes.

The word suzerain is used in the Pretoria convention of the 3rd of August 1881 between the British government and the late South African Republic. The convention (by its preamble) granted to the inhabitants complete self-government, "subject to the suzerainty of her Majesty," and this suzerainty was reaffirmed in the articles. Even when the convention was being negotiated doubts arose as to its meaning, and legal authorities were divided as to its effect (see speech of Lord Cairns, *Hansard*, 269, p. 261; Lord Selborne, 260, p. 309; answer of attorney-general 260, 1534). It was doubtful whether territory could be ceded by the Crown of its own authority; and if the power existed the cession could, it was said, be made only by virtue of clear words. From the articles substituted in the London convention of the 27th of February 1884 for those of 1881, the word "suzerainty" was omitted. Fresh doubts arose as to the effect of this omission; and a correspondence on the subject took place between the British government and the government of the republic before the outbreak of hostilities in South Africa, the former maintaining that the preamble of 1881, by which alone any self-government was granted, was still in force, and therefore that the suzerainty—whatever it involved—remained; the Transvaal government, on the other hand, contending that the suzerainty had been abolished by the substitution of the 1884 convention for that of 1881. Writers on international law differ greatly as to the exact position of the South African republic under the later convention. Some considered it an independent sovereign state. Mr Taylor (*A Treatise of International Public Law*, p. 174) treats the Transvaal after the convention of 1884 as a "neutralized state only part sovereign." Other writers describe the relation as that of a protectorate (see Professor J. Westlake, *Revue de droit international*, 1896, p. 268 seq.; *International Law*, pt. 1, p. 27). Professor de Louter defines it as "une servitude du droit des gens (servitus juris gentium), et qui diffère de la servitude du droit privé en ce qu'elle ne constitue pas un droit réel (jus in re aliena) mais un droit entre deux personnes de droit international (subjecta juris gentium)" (*Revue de droit international*, 1899, p. 330). Dr F. Von Liszt (*Das Völkerrecht*, p. 331) treats the South African republic as an example of a half sovereign state. M. Gairal describes it as a vassal state. Probably the soundest opinion is that the British Crown reserved no other rights than those expressly stated in the convention of 1884.

See Stubbs, "Suzerainty, or the Rights and Duties of Suzerain and Vassal States" (1882), *Revue de droit international* (1896), pp. 39, 278; Westlake, "L'Angleterre et la république sud-africaine," *Revue de droit international* (1896), p. 268; Bornhak, *Einseitige Abhängigkeitsverhältnisse unter den modernen Staaten* (1896); Ullmann, *Völkerrecht* (1908), p. 25; Tchomacoff, *De la Souveraineté* (1901); Jellinek, *Die Lehre von den Staatenverbindungen* (1882); *Correspondence Relating to South African Republic* (1899) [C. 9507]; *Law Magazine* (1900), p. 413; *Law Quarterly Review* (1896), p. 122; *Journal of Comparative Legislation*, new series, vol. i. p. 432; Merignhac, *Droit public international* (1905), p. 204. (J. M.)

SVANE [or SVANING], **HANS** (1606–1668), Danish statesman and ecclesiastic, was born on the 27th of March 1606, at Horsens, where his father, Hans Riber, was burgomaster. His mother Anne was a daughter of the historian Hans Svaning, whose name, subsequently altered to Svane, he adopted. At Copenhagen Svane devoted himself to the study of Oriental languages, and between 1628 and 1635 completed his education abroad, at Franeker in Friesland, Wittenberg, Oxford and Paris. After seven years' residence abroad Svane returned to occupy the chair of Oriental languages at the university of Copenhagen. In 1646, finding promotion slow, he turned to theology and was "created" Dr theol. by his old patron Jesper Brochmand, now bishop of Sjaelland, whom he succeeded in the metropolitan see of Denmark on the 26th of January 1655. As a theologian he belonged to the severely orthodox Lutheran school. His scholarship, despite the erudition of his commentary to the prophet Daniel in two huge folio volumes, is questionable. But in Latin and Danish he won distinction as a speaker, and his funeral orations in both languages were admired by his contemporaries. At the famous *rigsdag* of 1660 he displayed debating talent of a high order and played an important political rôle. It was Svane who, at the opening of the *rigsdag*, proposed that only members of the council of state should be entitled to fiefs and that all other estates should be leased to the highest bidder whatever his social station. At a hint from the king he laboured to get the royal charter abolished and the elective monarchy transformed into an hereditary monarchy. The clerical deputies followed him in a serried band, as the burgesses followed Nansen, and the bishop's palace was one of the meeting-places for the camarilla which was privy to the absolutist designs of Frederick III. Throughout the session Svane was chairman of "the Conjoined Estates" in their attacks upon the nobility, his watchword being: Equal rights for all and a free hand for the king. It was on his motion (Oct. 8) that the Commons agreed "to offer his majesty the crown as an hereditary crown," to which proposition the nobility acceded, under severe pressure, two days later. When, on the 13th, the three estates assembled at the castle, it was Svane's speech, as president of the estate of the clergy, which gave the solemnity its ultra-royalist character. He, too, quashed the timid attempt of the more liberal minded of the deputies to obtain a promise from the king of some sort of a constitution. In fact, excepting the king and queen, nobody contributed so powerfully to the introduction of absolutism into Denmark as the bishop of Copenhagen. He was raised to the dignity of archbishop, a title which no other Danish prelate has since borne, and as president of the academic consistory of the university (an office which was invented for and died with him) he took precedence of the rector magnificus. He was also created a royal councillor, an assessor of the supreme court and a member of the *stats kollegiet* or council of state. His elevation seems to have turned his head. The university suffered the most from his extravagant pretensions; and his quarrels with all the professors at last caused such a scandal that the king had to interfere personally. A bishop who was at the same time a privy councillor, a minister of state and a judge of the supreme court could have but little time for spiritual duties. Yet Svane was not altogether neglectful of them. Especially noteworthy is his plan for the erection of a consistorial college for managing all the temporal affairs of the church, including education and poor relief, anticipating to some extent the modern ministries of education and public worship, which unfortunately was not adopted. Moreover, the privileges which he obtained for the clergy did much to increase the welfare and independence of the Danish Church in difficult times, while his representations to the king that Danish theology was not likely to be promoted by placing Germans over the heads of native professors bore good fruit. Svane died on the 26th of July 1668, in his 62nd year.

See Detlev Gotthard Zwergius, *Siellandske clerisie* (Copenhagen, 1754). (R. N. B.)

SVANETIA, a mountainous district on the south slopes of the Caucasus, immediately underneath the loftiest glaciated peaks of the middle of the system. It extends over the upper valleys of the Rion, Ingur and Tskhenis-tskhali, and is included in the modern government of Kutais. The Svanetians belong to the Georgian race. (See CAUCASIA and CAUCASUS.)

SVENDBORG, a seaport of Denmark, capital of the *amt* (county) of its name, on the south shore of the island of Fünen. Pop. (1901), 11,543. The situation is pleasant. The narrow Svendborg Sund separates Fünen from the lesser islands of Taasinge and Turö, of which the former rises to 245 ft. Inland from the town there is also elevated ground, the Ovinehöi. The harbour is accessible to vessels drawing 20 ft. There are tobacco and earthenware manufactories, boat-building yards, and distilleries. Butter is the principal export, and petroleum, coal and iron the imports. Neighbouring to the town are the ruined castle of Örkil, the watering-place Christiansminde, and the extensive orchards of Gammel Hestehave, where wine is produced.

SVENDSEN, JOHANN SEVERIN (1840–), Norwegian composer, was born in Christiania on the 30th of September 1840. He learnt the elements of music and violin-playing from his father, and after serving for some time in the army, and later touring as violinist with a troup of instrumentalists, he entered the conservatorium at Leipzig through the aid of the king of Sweden. After another tour, which extended to the British Isles, Svendsen spent a year in Paris, and in 1871–1872 was leader of the once famous Euterpe concerts in Leipzig. In 1871 he married an American, and from 1872 to 1877 he conducted the Christiania Musical Society, while in 1877–1879 he lived in Rome, London and Paris. In 1883 Svendsen became court kapellmeister at Copenhagen. Probably we have to go back to Schubert to find a composer whose Opus 1 has attained the wide popularity of Svendsen's A minor string quartet, while his beautiful octet, Opus 3, added to his fame. Though Svendsen was at one time intimate with Wagner, the latter does not seem to have influenced his music, which includes two symphonies, a violin concerto, and a romance for violin, as well as a number of Norwegian rhapsodies for the orchestra.

SVERDRUP, JOHAN (1816–1892), Norwegian statesman, was born at Jarlsberg on the 30th of July 1816. His father, Jakob Sverdrup, was a land steward, and the founder of the first school of agriculture in Norway. Johan entered the Storthing in 1850, sitting first for Laurvik, and then for the district of Akershus, and was its president from 1871 to 1884, during the whole of the dispute over the prerogative of the Crown. He built up a strong political party, which, relying for support chiefly on the Norwegian peasantry, was determined to secure strict constitutional government and practically to destroy the power of the king. Under his leadership the opposition, in 1872, secured the passing of a bill for the admission of the ministers to the Storthing, which was a step to the establishment of the dependence of the cabinet on a majority in that assembly. King Charles XV. refused his sanction to this bill, and on its third passing in 1880 Oscar II. opposed his veto, at the same time claiming his right to the absolute veto. Sverdrup then proposed the proclamation of the law in defiance of the king's action. The retirement of Frederik Stang removed Sverdrup's chief political opponent from the field. He was aided in his campaign by Björnstjerne Björnson, and after a series of political crises he became prime minister in June 1884. But when he became prime minister he soon found himself at issue with Björnson on church matters. Inspired chiefly by his nephew Johan he secured the refusal of a pension to the novelist Kielland because of his anti-clerical views, and he further wished to give the parish councils the right to strike off the voting list persons who had broken away from church discipline. Therefore, although during his term of office no fewer than eighty-nine measures, many of them involving useful reforms, became law, he failed to satisfy the extremists among his supporters, and was driven to rely on the moderate Liberals. He was compelled to retire in 1889, and died on the 17th of February 1892 at Christiania.

SWABIA, SUABIA or SUEVIA (Ger. *Schwaben*), one of the stem-duchies of medieval Germany, taking its name from the Suevi, a tribe who inhabited the district in the first century of the Christian era. Dwelling in the angle formed by the Rhine and the Danube, they were joined by other tribes, and were called Alamanni, whilst the district was called Alamannia, until about the 11th century, when the form Swabia began to prevail. In 496 the Alamanni were defeated by Clovis, king of the Franks, brought under Frankish rule, and governed by dukes who were dependent on the Frankish kings. In the 7th century the people were converted to Christianity, bishoprics were founded at Augsburg and Constance, and in the 8th century abbeys at Reichenau and St Gall. The Alamanni had gradually thrown off the Frankish yoke, but in 730 Charles Martel again reduced them to dependence, and his son Pippin the Short abolished the tribal duke and ruled the duchy by two counts palatine, or *Kammerboten*.

The duchy, which was divided into *gaus* or counties, took about this time the extent which it retained throughout the middle ages, and was bounded by the Rhine, the lake of Constance, the Lech and Franconia. The Lech, separating Alamannia from Bavaria, did not form, either ethnologically or geographically, a very strong boundary, and there was a good deal of intercommunion between the two races. During the later and weaker years of the Carolingian rule the counts became almost independent, and a struggle for supremacy took place between them and the bishops of Constance. The chief family in Alamannia was that of the counts of Raetia, who were sometimes called margraves, and one of whom, Burkhard, was called *duke of the Alaminnia*. Burkhard was killed in 911, and two counts palatine, Bertold and Erchanger, were accused of treason, and put to death by order of the German king Conrad I. In 917, Burkhard, count in Raetia, took the title of duke, and was recognized as such by King Henry I., the Fowler, in 919. His position was virtually independent, and when he died in 926 he was succeeded by Hermann, a Franconian noble, who married his widow. When Hermann died in 948 Otto the Great gave the duchy to his own son Ludolf, who had married Hermann's daughter Ida; but he reduced the ducal privileges and appointed counts palatine to watch the royal interests. Ludolf revolted, and was deposed, and other dukes followed in quick succession. Burkhard II., son of Burkhard I., ruled from 954 to 973, Ludolf's son, Otto, afterwards duke of Bavaria, to 982, and Conrad I., a relative of Duke Hermann I., until 997. Hermann II., possibly a son of Conrad, succeeded, and, dying in 1003, was followed by his son Hermann III. During these years the Swabians were loyal to the kings of the Saxon house, probably owing to the influence of the bishops. Hermann III. had no children, and the succession passed to Ernest, son of his eldest sister Gisela and Ernest I., margrave of Austria. Ernest held the duchy for his son until his own death in 1015, when Gisela undertook the government, and was married a second time, to Conrad, duke of Franconia, who was afterwards the German king Conrad II. When Ernest came of age he quarrelled with his step-father, who deposed him, and, in 1030, gave the duchy to Gisela's second son, Hermann IV. and, on his death in 1038, to Henry, his own son by Gisela. In 1045 Henry, who had become German king as Henry III., granted Alamannia to Otto, grandson of the emperor Otto II. and count palatine of the Rhine, and, in 1048, to Otto, count of Schweinfurt. Rudolph, count of Rheinfelden, was the next duke, and in 1077 he was chosen German king in opposition to the emperor Henry IV., but found little support in Swabia, which was given by Henry to his faithful adherent, Frederick I., count of Hohenstaufen. Frederick had to fight for his position with Bertold, son of Duke Rudolph, and the duke's son-in-law, Bertold II., duke of Zähringen, to whom he ceded the Breisgau in 1096. Frederick II. succeeded his father in 1105, and was followed by Frederick III., afterwards the emperor Frederick I. The earlier Hohenstaufen increased the imperial domain in Swabia, where they received steady support, although ecclesiastical influences were very strong. In 1152 Frederick I. gave the duchy to his kinsman, Frederick, count of Rothenburg and duke of Franconia, after whose death in 1167 it was held successively by three sons of the emperor, the youngest of whom, Philip, was chosen German king in 1198. During his struggle for the throne Philip purchased support by large cessions of Swabian lands, and the duchy remained in the royal hands during the reign of Otto IV., and came to Frederick II. in 1214. Frederick granted Swabia to his son Henry, and, after his rebellion in 1235, to his son Conrad, whose son Conradin, setting out in 1266 to take possession of Sicily, pledged his Swabian inheritance to Ulrich II. count of Württemberg. The duchy was ripe for dissolution and, after Conradin's death, in 1268, the chief authority in Swabia fell to the counts of Württemberg, the margraves of Baden, the counts palatine of Tübingen, the counts of Hohenzollern and others.

When the emperor Maximilian I. divided Germany into circles in 1512, one, which was practically coterminous with the duchy, was called the Swabian circle. The area, which was formerly Swabia, is now covered by the kingdom of Württemberg, the grand-duchy of Hesse and the western part of the kingdom of Bavaria. Although the name Swabia is occasionally used in a general way to denote the district formerly occupied by the duchy, the exact use of the name is now confined to a Bavarian province, with its capital at Augsburg.

See J. Leichtlen, *Schwaben unter den Römern* (Freiburg, 1825); J. C. v. Pfister, *Pragmatische Geschichte von Schwaben* (Heilbronn, first part, 1803, continuation to 1496, 1827).

SWABIAN LEAGUE, an association of German cities, principally in the territory which had formed the old duchy of Swabia. The name, though usually given to the great federation of 1488, is applicable also to several earlier leagues (*e.g.* those of 1331, 1376). The Swabian cities had attained great prosperity under the protection of the Hohenstaufen emperors, but the extinction of that house in 1268 was followed by disintegration. Cities and nobles alike, now owing allegiance to none but the emperor, who was seldom able to defend them, were exposed to the aggression of ambitious princes.

In 1331, twenty-two Swabian cities, including Ulm, Augsburg, Reutlingen and Heilbronn, formed a league at the instance of the emperor Louis the Bavarian, who in return for their support promised not to mortgage any of them to a vassal. The count of Württemberg was induced to join in 1340. Under Charles IV. the lesser Swabian nobles began to combine against the cities, and formed the *Schlegelerbund* (from *Schlegel*, a maul). Civil war ensuing in 1367, the emperor, jealous of the growing power of the cities, endeavoured to set up a league under his own control, for the maintenance of public peace (*Landfriedensbund*, 1370). The defeat of the city league by Eberhard II. of Württemberg in 1372, the murder of the captain of the league, and the breach of his obligations by Charles IV., led to the formation of a new league of fourteen Swabian cities led by Ulm in 1376. This league triumphed over the count of Württemberg at Reutlingen in 1377, and the emperor having removed his ban, it assumed a permanent character, set up an arbitration court, and was rapidly extended over the Rhineland, Bavaria and Franconia. In 1382 an alliance was made at Ehingen with the archduke of Austria, and through his mediation with the three chief knightly associations of Swabia. The new king, Wenceslaus, hoped at first, like his father Charles, to check the federal movement by associating all estates of the realm under his own lead in *Landfriedenseinigungen*, but such a compact made at Heidelberg in 1384, although renewed at Mergentheim three years later, was a mere makeshift. The struggle between burghers and nobles was precipitated by the inclusion of the urban members of the Swiss confederation in the league in 1385 and the overthrow of Archduke Leopold of Austria by the latter at Sempach in the following year. A quarrel between the duke of Bavaria and the archbishop of Salzburg gave the signal for a general war in Swabia, in which the cities, weakened by their isolation, mutual jealousies and internal conflicts, were defeated by Count Eberhard II. at Döffingen (Aug. 24, 1388), and were severally taken and devastated. Most of them quietly acquiesced when Wenceslaus proclaimed a *Landfriede* at Eger in 1389 and prohibited all leagues between cities. The professed aims of the cities which had formed this league of 1376 were the maintenance of their imperial status (*Reichsunmittelbarkeit*), security against sale or mortgage and against excessive taxation, the protection of property, trade and traffic, and the power to suppress disturbances of the peace. There is no trace of co-operation with the Hanseatic towns. The league necessarily opposed the pretensions of the emperors and the electoral princes, especially as set forth in the Golden Bull, and in accordance with the growing spirit of civil freedom demanded a share in the government, but that there was any widespread conscious desire for a fundamental change in the constitution, for the abolition of aristocratic privilege or for a republic, as certain historians maintain, is improbable (K. Klüpfel, *Der schwäbische Bund*).

For nearly a century there was no great effort at federation among the Swabian cities, attention being diverted to the ecclesiastical controversies of the time, but there were partial and short-lived associations, *e.g.* the league of twelve Swabian cities in defence of their liberties in 1392, the Marbach league in 1405 against the German king, Rupert, and in 1441 the union of twenty-two cities (in 1446 thirty-one) headed by Ulm and Nuremberg, for the suppression of highway robbery. This latter union in 1449 formed a standing army and waged war on a confederation of princes led by Albert Achilles, afterwards elector of Brandenburg (*q.v.*).

The growing anarchy in Swabia, where the cities were violently agitated by the constant infringement of their liberties (*e.g.* the annexation of Regensburg by Bavaria in 1486), induced Frederick III., who required men and money for the Hungarian War, to conciliate the cities by propounding a scheme of pacification and reform. His commissioner, Count Hugo of Werdenberg, met the Swabian estates at Esslingen and laid before them a plan probably drawn up by Bertold, elector of Mainz, and on the 14th of February 1488 the Great Swabian League was constituted. There were four constituent parties, the archduke Sigismund of Austria, Count Eberhard V. (afterwards duke) of Württemberg, who became the first captain of the league, the knightly league of St George, and lastly twenty-two Swabian imperial cities. The league received a formal constitution with a federal council consisting of three colleges of nine councillors each, a captain and a federal court with judicial and executive powers. The armed force which was to police Swabia consisted of 12,000 foot and 1200 horse, each party contributing one-fourth. The league gained strength by the speedy accession of Augsburg and other Swabian cities, the margraves of Brandenburg-Ansbach, Baireuth and Baden, the four Rhenish electors, &c., and in 1490 of Maximilian, king of the Romans, whom the league had helped to rescue from the hands of the Netherlanders in 1488. It did not render him the support he expected in his foreign policy, but it performed its primary work of restoring and maintaining order with energy and efficiency. In 1492 it compelled Duke Albert of Bavaria to renounce Regensburg; in 1519 it expelled the turbulent duke, Ulrich of Württemberg, who had seized Reutlingen, and it sold his duchy to Charles V.; and in 1523 it defeated the Franconian knights who had taken up arms with Franz von Sickingen. In 1525, Truchsess, the league captain, aided by the forces of Trier and the palatinate, overthrew the rebel peasants of Königshofen on the Tauber and at Ingolstadt.

The league, which had been several times renewed, expired on the 2nd of February 1534, its dissolution being due to internal dissensions regarding the reformation. Futile attempts were made to renew it, in 1535 by the Bavarian chancellor, Eck, and in 1547 by Charles V.

See E. Osann, *Zur Geschichte des schwäbischen Bundes* (Giessen, 1861); K. Klüpfel, "Der schwäbische Bund" (in *Hist. Taschenbuch*, 1883–1884), *Urkunden zur Geschichte des schwäbischen Bundes* (Stuttgart, 1846–1853). (A. B. Go.)

SWADLINCOTE, a town in the southern parliamentary division of Derbyshire, England, 15 m. S.S.W. of Derby, and 4 m. S.E. of Burton-upon-Trent, on the Midland railway. Pop. (1901), urban district of Swadlincote district, 18,014. This includes the civil parishes of Swadlincote, Church Gresley and Stanton and Newhall, which together form a large industrial township, mainly devoted to the manufacture of earthenware and fireclay goods. There are collieries in the neighbourhood.

SWAFFHAM, a market town in the south-western parliamentary division of Norfolk, England; 111 m. N.N.E. from London by the Great Eastern railway. Pop. of urban district (1901), 3371. The town lies high, in an open, healthy district. The church of St Peter and St Paul is Perpendicular, a handsome cruciform structure with central tower, and has a fine carved roof of wood. The town, which has a town-hall and assembly rooms, possesses iron foundries and a considerable agricultural trade, with cattle fairs. At Castle Acre, 4 m. N., are the picturesque ruins of a Cluniac priory, founded shortly after the Conquest by William de Warren. These comprise portions of the church, including the fine west front, arcaded, with three Norman doors and a Perpendicular window, with the chapter-house, cloisters and conventual buildings. The majority of the remains are Norman or Perpendicular. The castle of the same founder has left little but its foundations, but it was erected within the protection of a remarkable series of earthworks, which remain in good condition. These are apparently in part Roman, in part earlier. The site, on which Roman coins, pottery and other remains have been discovered, was on an ancient trackway running north and south. It may be noted that de Warren founded a similar castle and priory at Lewes in Sussex. The church of St James, Castle Acre, contains good Early English and Perpendicular work.

SWAHILI (*Wa-Swahili*, *i.e.* coast people, from the Arabic *sāhil*, coast), a term commonly applied to the inhabitants of Zanzibar and of the opposite mainland between the parallels of 2° and 9° S., who speak the Ki-Swahili language. The Swahili are essentially a mixed people, the result of long crossing between the negroes of the coast and the Arabs, with an admixture of slave blood from nearly all the East African tribes. Among Swahili are found every shade of colour and every type of physique from the full-blooded negro to the pure Semite. Usually they are a powerfully built, handsome people, inclined to stoutness and with Semitic features. They number about a million. They figured largely in the history of African enterprise during the 19th century. The energy and intelligence derived from their Semitic blood have enabled them to take a leading part in the development of trade and the industries, as shown in the wide diffusion of their language, which, like the Hindustani in India and the Guarani in South America, has become the principal medium of intercommunication in a large area of Africa south of the equator. During his journey from the Indian Ocean to the Atlantic (1873–1874) Commander V. Lovett Cameron found that a knowledge of this language enabled him everywhere to dispense with the aid of an interpreter, as it was understood by one or more persons in all the tribes along the route. Owing to this circumstance the Swahili have been found invaluable assistants in every expedition from the eastern seaboard to the interior after they began to be employed by J. H. Speke and Richard Burton as porters and escorts in 1857. The language is somewhat archaic Bantu, much mixed with Arabic, while Indian, Persian and even English, Portuguese and German words have contributed to the vocabulary. Grammatical treatises on it have been published, and into it portions of the Bible have been translated by Bishop Steere.[1] The Swahili are Mahommedans, but in disposition are genuine negroes. Christian missions among them have met with little success.

See Johann Ludwig Krapf, *Dictionary of Swahili Language* (London, 1882); Bishop Steere, *Handbook of the Swahili Language* (London, 1894); *Collection of Swahili Folk-Tales* (1869); A. C. Madan, *English-Swahili Dictionary* (Oxford, 1894); Delaunay, *Grammaire Kiswahili* (Paris, 1898). See also BANTU LANGUAGES.

SWALLOW (A. S. *swalewe*, Icel. *svala*, Du. *zwaluw*, Ger. *Schwalbe*), the bird which of all others is recognized as the harbinger of summer in the northern hemisphere. The name *Hirundo rustica* of Linnaeus is now employed for the common chimney-swallow of Europe, which has been divided into four or five races. In summer it ranges all over Europe, and in Asia extends to Manchuria and China; in winter it migrates south, reaching India, Burma, the Malay Peninsula and the whole of Africa. The common swallow of North America, usually called the barn-swallow, is *H. erythrogastra*, but in summer it also reaches Alaska and Greenland and extends across to Lake Baikal. The winter migration extends to Burma for the Asiatic swallows and to South Brazil for those of America. In all some twenty-seven species of Hirundo are recognized, the range of the genus being practically world-wide. Returning, usually already paired, to its summer haunts, after its winter sojourn in southern lands, and generally reaching England about the first week in April, the English swallow at once repairs to its old quarters, nearly always around the abodes of men; and, about a month later, the site of the nest is chosen, resort being had in most cases to the very spot that has formerly served the same purpose—the old structure, if still remaining, being restored and refurnished. So trustful is the bird that it commonly establishes itself in any of men's works that will supply the necessary accommodation, and a shed, a barn, or any building with an open roof, a chimney that affords a support for the nest, or even the room of an inhabited house—if chance should give free access thereto—to say nothing of extraordinary positions, may be the place of its choice. Wheresoever placed, the nest is formed of small lumps of moist earth, which, carried to the spot in the bird's bill, are duly arranged and modelled, with the aid of short straws or slender sticks, into the required shape. This is generally that of a half-saucer, but it varies according to the exigencies of the site. The materials dry quickly into a hard crust, which is lined with soft feathers, and therein are laid from four to six white eggs, blotched and speckled with grey and orange-brown deepening into black. Two broods are usually reared in the season, and the young on leaving the nest soon make their way to some leafless bough, whence they try their powers of flight, at first accompanying their parents in short excursions on the wing, receiving from them the food which they are as yet unable to capture, until able to shift for themselves. They collect in flocks, often of many hundreds, and finally leave the country about the end of August or early in September, to be followed, after a few weeks, by their progenitors. They moult their feathers in their winter quarters, and this fact affords one of the strongest arguments against the popular belief (which, curious to say, is still partly if not fully entertained by many who should know better) of their becoming torpid in winter, for a state of torpidity would suspend all animal action.[2] The chestnut forehead and throat, the shining steel-blue upper plumage, and the dusky white—in some cases reddening so as almost to vie with the frontal and gular patches—of the lower parts are well known to every person of observation, as is the markedly forked tail, which is become proverbial of this bird.

Taking the word swallow in a more extended sense, it is used for all the members of the family Hirundinidae,[3] excepting a few to which the name martin (*q.v.*) has been applied, and this family includes from 80 to 100 species, which have been placed in many different genera. The true swallow has very many affines, some of which range almost as widely as itself does, while others seem to have curiously restricted limits, and much the same may be said of several of its more distant relatives. But altogether the family forms one of the most circumscribed and therefore one of the most natural groups of Oscines, having no near allies; for, though in outward appearance and in some habits the swallows bear a considerable resemblance to swifts (*q.v.*), the latter belong to a different order, and are not Passerine birds at all, as their structure, both internal and external, proves. It has been sometimes stated that the Hirundinidae have their nearest relations in the flycatchers (*q.v.*); but the assertion is very questionable, and the supposition that they are allied to the Ampelidae (cf. WAXWING), though possibly better founded, has not been confirmed. An affinity to the Indian and Australian *Artamus* (the species of which genus are often known as wood-swallows or swallow-shrikes) has also been suggested but has not been accepted. (A. N.)

SWALLOW-HOLE, in physical geography the name applied to a cavity resulting from the solution of rock under the action of water, and forming, or having at some period formed, the entrance to a subterranean stream-channel. Such holes are common in calcareous (limestone or chalky) districts, or along the line of outcrop of a limestone belt among non-calcareous strata. These cavities are also known as sinks, dolinas or butter-tubs, and by other local names, and sometimes as pot-holes; the last term, however, is also synonymous with Giant's Kettle (*q.v.*). See CAVE.

SWAMMERDAM, JAN (1637–1680), Dutch naturalist, was born on the 12th of February 1637 at Amsterdam, the son of an apothecary and naturalist. He was destined for the Church; but he preferred the profession of medicine, taking his doctor's degree at Leiden in 1667. Having necessarily to interest himself in human anatomy, he devoted much attention to the preservation and better demonstration of the various structures, and he devised the method of studying the circulatory system by means of injections. He also spent much time in the study of insects, investigating the subject of their metamorphosis, and in this and other ways laying the beginnings of their natural classification, while his researches on the anatomy of mayflies and bees were also of great importance. His devotion to science led to his neglect of practice; his father, resenting this, stopped all supplies and thus Swammerdam experienced a period of considerable privation, which had the most unfortunate consequences to his health, both bodily and mental. In 1675 his father died, leaving him an adequate fortune, but the mischief was irreparable. He became a hypochondriac and mystic, joined the followers of Antoinette Bourignon, and died at Amsterdam on the 15th of February 1680.

His *Allgemeene Verhandeling van bloedeloose diertjens* appeared at Utrecht in 1669, and his *Biblia naturae, sive Historia insectorum in certas classes redacta* was published after his death by H. Boerhaeve in 1737–1738. He was also the author of *Miraculum naturae, seu Uteri muliebris fabrica* (Leiden, 1672).

SWAN, JOHN MACALLAN (1847–1910), English painter and sculptor, received his art training first in England at the Worcester and Lambeth schools of art and the Royal Academy schools, and subsequently in Paris, in the studios of J. L. Gérôme and E. Frémiet. He began to exhibit at the Academy in 1878, and was elected associate in 1894 and academician in 1905. He was appointed a member of the Dutch Water-Colour Society in 1885; and associate of the Royal Society of Painters in Water Colours in 1896 and full member in 1899. A master of the oil, water-colour and pastel mediums, an accomplished

[1] The language was first reduced to writing by the Arabs, who still use the Arabic character. But the European missionaries have replaced this by the Roman system, which is more suited for the transliteration of most African, and especially of the Bantu, tongues.

[2] See John Hunter's *Essays and Observations in Natural History*, edited by Sir R. Owen in 1861 (ii. 280). An excellent bibliography of the swallow-torpidity controversy, up to 1878, is given by Professor Coues (*Birds of the Colorado Valley*, pp. 378–390), who seems still to hanker after the ancient faith in "hibernation."

[3] An enormous amount of labour has been bestowed upon the Hirundinidae by R. B. Sharpe (*Cat. B. Brit. Mus.* x. 85–210), and in the finely-illustrated *Monograph* which he and C. W. Wyatt have published (2 vols. 4to, London, 1885–1894).

painter and a skilful draughtsman, he ranks also as a sculptor of distinguished ability. He has treated the human figure with notable power, but it is by his representations of the larger wild animals, mainly the felidae, that he chiefly established his reputation; in this branch of practice he has scarcely a rival. His picture "The Prodigal Son," bought for the Chantrey collection in 1889, is in the National Gallery of British Art. He was awarded first class gold medals for painting and sculpture in the Paris Exhibition, 1900. He died on the 14th of February 1910.

See SCULPTURE; "The Work of J. M. Swan," by A. L. Baldry, in *The Studio*, vol. xxii.; and *Drawings of John M. Swan, R.A.* (George Newnes, Ltd.).

SWAN, SIR JOSEPH WILSON (1828–   ), English physicist and electrician, was born at Sunderland on the 31st of October 1828. After serving his apprenticeship with a chemist in his native town, he became first assistant and later partner in a firm of manufacturing chemists in Newcastle. Among its operations this firm included the manufacture of photographic plates, and thus Swan was led to one of the advances in photography with which his name is associated—the production of extremely rapid dry plates, which were the outcome of an original observation made by him on the effect of heat in increasing the sensitiveness of a gelatino-bromide of silver emulsion. In 1862 he patented the first commercially practicable process for carbon printing in photography. This depended on the fact that when gelatine is exposed to light in the presence of bichromate salts it is rendered insoluble and non-absorbent of water. Swan took a surface of gelatine, dusted over with lampblack and sensitized with bichromate of ammonium, and exposed it to light below a photographic negative; the result was to make the gelatine from the surface downwards insoluble to a depth depending on the intensity, and therefore penetration, of the light which had reached it through the negative. In this operation the surface of the gelatine was also rendered insoluble, and it therefore became necessary to get at its back in order to be able to wash away the portions that still remained soluble; this was effected by cementing the insoluble surface to a fresh sheet of paper by means of indiarubber solution, and then detaching the original support. It thus became possible to reach the soluble portions with water and to obtain a representation of the picture, though reversed as to right and left, in relief on the pigmented gelatine. This process has been simplified and improved by subsequent workers, but in its essential features it forms the basis of some of the methods of photographic reproduction most widely used at the present day. But Swan's name deserves remembrance even more in connexion with the invention of the incandescent electric lamp than with improvements in photographic technique. He was one of the first to undertake the production of an electric lamp in which the light should be produced by the passage of an electric current through a carbon filament, and he was almost certainly far ahead, in point of time, of any other worker in the same field in realizing the conditions to be met and the difficulties to be overcome. So far back as 1860 he constructed an electric lamp with a carbon filament, which was formed by packing pieces of paper or card with charcoal powder in a crucible and subjecting the whole to a high temperature. The carbonized paper thus obtained he mounted in the form of a fine strip in a vacuous glass vessel and connected it with a battery of Grove's cells, which though not strong enough to raise it to complete incandescence, were sufficient to make it red-hot. This was substantially the method adopted by Edison nearly twenty years later, after various fruitless efforts to make a practical lamp with a filament of platinum or a platinum alloy had convinced him of the unsuitability of that metal for the purpose—a conclusion which Swan had reasoned out for himself many years before. By the time Edison had hit upon the idea of carbonizing paper or bamboo by heat to form the filament, Swan had devised the further improvement of using cotton thread "parchmentized" by the action of sulphuric acid, and it was by the aid of such carbon filaments that on the 20th of October 1880 he gave at Newcastle the first public exhibition on a large scale of electric lighting by means of glow lamps. In another method devised by him for the manufacture of filaments, collodion was squirted into a coagulating solution and the tough threads thus obtained carbonized by heat. He also devoted attention to apparatus for measuring electric currents, to the improvement of accumulators and to the conditions governing the electro-deposition of metals. He was elected a fellow of the Royal Society in 1894, and served as president of the Institution of Electrical Engineers in 1898–1899 and of the Society of Chemical Industry in 1901. In the last-named year he received the honorary degree of D.Sc. from Durham University, and he was knighted in 1904.

SWAN (A. S. *swan* and *swon*, Icel. *svanr*, Du. *zwaan*, Ger. *Schwan*), a large swimming-bird, well known from being kept in a half-domesticated condition throughout many parts of Europe, whence it has been carried to other countries. In England it was far more abundant formerly than at present, the young, or cygnets,[1] being highly esteemed for the table, and it was under especial enactments for its preservation, and regarded as a "bird royal" that no subject could possess without licence from the Crown, the granting of which licence was accompanied by the condition that every bird in a "game" (to use the old legal term) of swans should bear a distinguishing mark of ownership (*cygninota*) on the bill. Originally this privilege was conferred on the larger freeholders only, but it was gradually extended, so that in the reign of Elizabeth upwards of 900 distinct swan-marks, being those of private persons or corporations, were recognized by the royal swanherd, whose jurisdiction extended over the whole kingdom. It is impossible here to enter into further details on this subject, interesting as it is from various points of view.[2] It is enough to remark that all the legal protection afforded to the swan points out that it was not indigenous to the British Islands, and indeed it is stated (though on uncertain authority) to have been introduced to England in the reign of Richard Cœur de Lion; but it it now so perfectly naturalized that birds having the full power of flight remain in the country. There is no evidence to show that its numbers are ever increased by immigration from abroad, though it is known to breed as a wild bird not farther from the British shores than the extreme south of Sweden and possibly in Denmark, whence it may be traced, but with considerable vacuities, in a south-easterly direction to the valley of the Danube and the western part of Central Asia. In Europe, however, no definite limits can be assigned for its natural range, since birds more or less reclaimed and at liberty consort with those that are truly wild, and either induce them to settle in localities beyond its boundary, or of themselves occupy such localities, so that no difference is observable between them and their untamed brethren. From its breeding-grounds, whether they be in Turkestan, in south-eastern Europe or Scania, the swan migrates southward towards winter, and at that season may be found in north-western India (though rarely), in Egypt, and on the shores of the Mediterranean.

The swan just spoken of is by some naturalists named the mute or tame swan, to distinguish it from one to be presently mentioned, but it is the swan simply of the English language

[1] Here, as in so many other cases, we have what may be called the "table-name" of an animal derived from the Norman-French, while that which it bore when alive was of Teutonic origin.

[2] The king and the Companies of Dyers and Vintners still maintain their swans on the Thames, and a yearly expedition is made in the month of August to take up the young birds—thence called "swan-upping" and corruptly "swan-hopping"—and mark them. The largest swannery in England, indeed the only one worthy of the name, is that belonging to Lord Ilchester, on the water called the Fleet, lying inside the Chesil Bank on the coast of Dorset, where from 700 to double that number of birds may be kept—a stock doubtless too great for the area, but very small when compared with the numbers that used to be retained on various rivers in the country. The swanpit at Norwich seems to be the only place now existing for fattening the cygnets for the table—an expensive process, but one fully appreciated by those who have tasted the results. The English swan-laws and regulations have been concisely but admirably treated by Serjeant Manning (*Penny Cyclopaedia*, xxiii. 271, 272).

and literature. Scientifically it is usually known as *Cygnus olor*. Its large size, its spotless white plumage, its orange-red bill, surmounted by a black knob (technically the "berry") larger in the male than in the female, its black legs and stately appearance on the water are familiar, either from figures innumerable or from direct observation, to almost every one. When left to itself its nest is a large mass of aquatic plants, often piled to the height of a couple of feet and possibly some six feet in diameter. In the midst of this is a hollow which contains the eggs, generally from five to nine in number, of a greyish-olive colour. The period of incubation is between five and six weeks, and the young when hatched are clothed in sooty-grey down, which is succeeded by feathers of sooty-brown. This suit is gradually replaced by white, but the young birds are more than a twelvemonth old before they lose all trace of colouring and become wholly white.

It was, however, noticed by Plot (*N.H. Staffordshire*, p. 228) more than 200 years ago that certain swans on the Trent had white cygnets; and it was subsequently observed of such birds that both parents and progeny had legs of a paler colour, while the young had not the "blue bill" of ordinary swans at the same age that has in some parts of the country given them a name, besides offering a few other minor differences. These, being examined by W. Yarrell led him to announce (*Proc. Zool. Society*, 1838, p. 19) the birds presenting them as forming a distinct species, *C. immutabilis*, to which the English name of "Polish" swan had already been attached by the London poulterers,[1] but which is now regarded merely as a variety, not in any way specially associated with Poland but possibly a dimorphic form.

The whooper, whistling or wild swan[2] of modern usage, *Cygnus musicus*, which was doubtless always a winter-visitant to Britain, though nearly as bulky and quite as purely white in its adult plumage, is at once recognizable from the species which has been half domesticated by its wholly different but equally graceful carriage, and its bill—which is black at the tip and lemon-yellow for a great part of its base. This entirely distinct species is a native of Iceland, eastern Lapland and northern Russia, whence it wanders southward in autumn, and the musical tones it utters (contrasting with the silence that has caused its relative to be often called the mute swan) have been celebrated from the time of Homer to our own. Otherwise in a general way there is little difference between the habits of the two, and very closely allied to the whooper is a much smaller species, with very well marked characteristics, known as Bewick's Swan, *C. bewicki*. This was first indicated as a variety of the last by P. S. Pallas, but its specific validity is now fully established. Apart from size, it may be externally distinguished from the whooper by the bill having only a small patch of yellow, which inclines to an orange rather than a lemon tint; while internally the difference of the vocal organs is well marked, and its cry, though melodious enough, is unlike. It has a more easterly home in the north than the whooper, but in winter not infrequently occurs in Britain.

Both the species last mentioned have their representatives in North America, and in each case the transatlantic bird is considerably larger than that of the Old World. The first is the trumpeter-swan, *C. buccinator*, which has the bill wholly black, and the second the *C. columbianus*—greatly resembling Bewick's swan, but with the coloured patches on the bill of less extent and deepening almost into scarlet. South America produces two very distinct birds commonly regarded as swans, *Cygnus melanocoryphus*, the black-necked swan, and that which is called *Coscoroba*. This last, *C. candida*, which inhabits the southern extremity of the continent to Chile and the Argentine territory and visits the Falkland Islands, is the smallest species known—pure white in colour except the tip of its primaries, but having a red bill and red feet.[3] The former, if not discovered by earlier navigators, was observed by Narbrough on the 2nd of August 1670 in the Strait of Magellan, as announced in 1694 in the first edition of his *Voyage* (p. 52). It was subsequently found on the Falkland Islands during the French settlement there in 1764–1765, as stated by Pernetty (*Voyage*, 2nd ed., ii. 26, 99), and was first technically described in 1782 by Molina (*Saggio sulla stor. nat. del Chile*, pp. 234, 344). Its range seems to be much the same as that of the Coscoroba, except that it comes farther to the northward, to the coast of southern Brazil on the east, and perhaps into Bolivia on the west. It is a very handsome bird, of large size, with a bright red nasal knob, a black neck and the rest of its plumage pure white. It has been introduced into Europe, and breeds freely in confinement.

A greater interest than attaches to the South American birds last mentioned is that which invests the black swan of Australia, *Chenopis atrata*. Considered for so many centuries to be an impossibility, the knowledge of its existence seems to have impressed (more perhaps than anything else) the popular mind with the notion of the extreme divergence—not to say the contrariety—of the organic products of that country. By a singular stroke of fortune we are able to name the precise day on which this unexpected discovery was made. The Dutch navigator Willem de Vlaming, visiting the west coast of Zuidland (Southland), sent two of his boats on the 6th of January 1697 to explore an estuary he had found. There their crews saw at first two and then more black swans, of which they caught four, taking two of them alive to Batavia; and Valentyn, who several years later recounted this voyage, gives in his work[4] a plate representing the ship, boats and birds, at the mouth of what is now known from this circumstance as Swan river, the most important stream of the thriving colony of West Australia, which has adopted this very bird as its armorial symbol. Valentyn, however, was not the first to publish this interesting discovery. News of it soon reached Amsterdam, and the burgomaster of that city, Witsen by name, himself a fellow of the Royal Society, lost no time in communicating the chief facts ascertained, and among them the finding of the black swans, to Martin Lister, by whom they were laid before that society in October 1698, and printed in its *Philosophical Transactions*, xx. 361. Subsequent voyagers, Cook and others, found that the range of the species extended over the greater part of Australia, in many districts of which it was abundant. It has since rapidly decreased in numbers, but is not likely soon to cease to exist as a wild bird, while its singular and ornamental appearance will probably preserve it as a modified captive in most civilized countries. The species scarcely needs description: the sooty black of its general plumage is relieved by the snowy white of its flight-feathers and its coral-like bill banded with ivory.

The Cygninae admittedly form a well-defined group of the family Anatidae, and there is now no doubt as to its limits, except in the case of the Coscoroba above mentioned. This bird would seem to be, as is so often found in members of the South American fauna, a more generalized form, presenting several characteristics of the Anatinae, while the rest, even its black-necked compatriot and the almost wholly black swan of Australia, have a higher morphological rank. Excluding from consideration the little-known *C. davidi*, of the five or six species of the northern hemisphere four present the curious character, somewhat analogous to that found in certain cranes (*q.v.*), of the penetration of the sternum by the trachea nearly to the posterior end of the keel, whence it returns forward and upward again to revert and enter the lungs; but in the two larger of these species, when adult, the loop of the trachea between the walls of the keel takes a vertical direction, while in the two smaller the bend is horizontal, thus affording an easy mode of recognizing the respective species of each. Fossil remains of more than one species of swan have been found. The most remarkable is *C. falconeri*, which was nearly a third larger than the mute swan, and was described from a Maltese cave by W. K. Parker in the Zoological Society's *Transactions*, vi. 119–124, pl. 30. (A. N.)

SWANAGE, a watering-place and seaport in the eastern parliamentary division of Dorsetshire, England, 9 m. S.S.W. from Bournemouth by sea, and 132 m. S.W. by W. from London by the London & South-Western railway. Pop. of urban district (1901), 3408. It lies on the picturesque Swanage Bay, on the east coast of the so-called Isle of Purbeck, the district lying south of Poole Harbour. The coast is wild and precipitous, and numerous caves occur in the cliffs. Inland are open, high-lying downs. Swanage Bay has a beautiful sandy beach affording excellent bathing. In the town, the church

[1] M. Gerbe, in his edition of Degland's *Ornithologie Européenne* (ii. 477), makes the amusing mistake of attributing this name to the *fourreurs* (furriers) of London, and of reading it *Cygne du pôle* (polar, and not Polish, swan)!

[2] In some districts it is called by wild-fowlers "elk," which perhaps may be cognate with the Icelandic *Alft* and the Old German *Elbs* or *Elps* (cf. Gesner, *Ornithologia*, pp. 358, 359), though by modern Germans *Elb-schwan* seems to be used for the preceding species.

[3] Dr Stejneger (*Proc. U. S. Nat. Museum*, 1882, pp. 177–179) has been at much pains to show that this is no swan at all, but merely a large Anatine form. Further research may prove that his views are well founded, and that this, with another very imperfectly known species, *C. davidi*, described by Swinhoe (*Proc. Zool. Soc.*, 1870, p. 430) from a single specimen in the Museum of Peking, should be removed from the sub-family Cygninae. Of *C. coscoroba* Mr Gibson remarks (*Ibis*, 1880, pp. 36, 37) that its "note is a loud trumpet-call," and that it swims with "the neck curved and the wings raised after the true swan model."

[4] Commonly quoted as *Oud en nieuw Oost Indien* (Amsterdam, 1726). The incidents of the voyage are related in Deel iii. Hoofdst. iv. (which has for its title Description of Banda), pp. 68–71.

of St Mary has a massive tower possibly of pre-Norman date; there are a town-hall, an institute with library and lecture hall, and memorials to a victory gained by King Alfred over the Danes in the bay in 877, and to Albert, Prince Consort. A large export trade is carried on in stone from the Purbeck quarries.

SWANSEA, a municipal, county and parliamentary borough, market town, and seaport of Glamorganshire, South Wales, finely situated in an angle between lofty hills, on the river Tawe or Tawy near its mouth in Swansea Bay, a beautiful recess of the Bristol Channel, 201 m. W. of London by rail and 45½ m. W.N.W. of Cardiff. The Great Western main line has a junction within the borough at Landore, whence a branch runs into a more central part of the town. The Vale of Neath branch of the same railway and the Rhondda & Swansea Bay railway (now worked by the Great Western) have terminal stations near the docks on the other (eastern) side of the river, as also has the Midland railway from Hereford and Brecon. All these lines approach the town from the north and east through an unattractive industrial district, but the central Wales branch of the London & North-Western railway from Craven Arms in entering it on the west passes through some beautiful woodlands and then skirts the bay, having parallel to it for the last 3 m. the light (passenger) railway which runs from Swansea to Mumbles Pier. The older part of the town, being the whole of the municipal borough previous to 1836, occupies the west bank of the Tawe near its mouth and is now wholly given up to business. Stretching inland to the north along the river for some 3 m. through Landore to Morriston, and also eastwards along the sea margin towards Neath, is the industrial quarter, while the residential part occupies the sea front and the slopes of the Town Hill (580 ft. high) to the west, stretching out to the pleasant suburb of Sketty. The east side of the river (known as St Thomas's and Port Tennant) is approached from the west by a road carried over the North Dock Lock and the river by two girder drawbridges, each of which has a double line of roadway (on which tramways are laid), two footpaths and a line of railway. All the main thoroughfares are spacious, and in two or three instances even imposing, but most of the residential part consists of monotonous stuccoed terraces. The climate is mild and relaxing and the rainfall averages about 40 in. annually.

Public Buildings, &c.—The old castle, first built by Henry de Newburgh about 1099, has entirely disappeared; but of the new castle, which was probably intended only as a fortified house, there remain the great and lesser halls, a tower and a so-called keep with the curtain wall connecting them, its chief architectural feature being a fine embattled parapet with an arcade of pointed arches in a style similar to that of the episcopal palaces of St Davids and Lamphey built by Henry Gower (d. 1347), bishop of St Davids, to whom the building of the new "castle" is also ascribed. Part of it is now used as the headquarters of the 4th Welsh (Howitzer) Brigade R.F.A. Possibly some traces of St Davids Hospital, built by the same prelate in 1331, are still to be seen at Cross Keys Inn. The parish church of St Mary was entirely rebuilt in 1895–1898. It previously consisted of a tower and chancel (with a fine Decorated window) built by Bishop Gower, the piers of the chancel arch being partly built on earlier Norman work, the Herbert Chapel (originally St Ann's) of about the same date as the chancel and rebuilt in the early part of the 16th century, and a nave built in 1739. Of the earlier work there remains the door of the rood loft (built into a wall), a 15th-century brass-inlaid marble slab with a representation of the resurrection, in memory of Sir Hugh Johnys (d. *c.* 1463) and his wife, and three canopied altar tombs—one with the effigy of a priest and another with effigies of Sir Matthew Cradock and his wife. Within the parish of St Mary was St John's, the church of a small parish of the same name lying to the north of St Mary's and once owned by the Knights Hospitallers. This church, which was entirely rebuilt in 1820, was renamed St Matthew in 1880, when a new St John's was built within its own parish. There are 26 other churches and 10 mission rooms belonging to the Church of England, besides 2 Roman Catholic churches, a synagogue and 84 Nonconformist chapels (31 Welsh and 53 English) and 20 mission rooms, but all are modern buildings. There are 9 ecclesiastical parishes and parts of two or three others, all in the diocese of St Davids. The Royal Institution of South Wales, founded in 1835, is housed in a handsome building in the Ionic style erected in 1838–1839 and possesses a museum in which the geology, mineralogy, botany and antiquities of the district are well represented, there being a fine collection of neolithic remains from the Gower Caves and from Merthyr Mawr. Its library is rich in historical and scientific works relating to Wales and Welsh industries and contains the collection of historical MSS. made by Colonel Grant-Francis, some time its honorary librarian, but one of its most valued possessions is the original contract of affiance between Edward II. (when prince of Wales) and Isabella. Its art gallery has many prints and drawings of great local interest and here the Swansea Art Society holds its annual exhibition. The Swansea Scientific Society also meets here. In its early days the institution was the chief centre of scientific activity in South Wales, those associated with its work including L. W. Dillwyn, James Motley, Dr Gutch and J. E. Bicheno, all botanists, J. Gwyn Jeffreys, conchologist, Sir W. R. Grove and the 1st Lord Swansea, the last three being natives of the town.

The free library and art gallery of the corporation, a four-storeyed building in Italian style erected in 1887, contains the library of the Rev. Rowland Williams (one of the authors of *Essays and Reviews*), the rich Welsh collection of the Rev. Robert Jones of Rotherhithe, a small Devonian section (presented by the Swansea Devonian Society), and about 8000 volumes and 2500 prints and engravings, intended to be mutually illustrative, given by the Swansea portrait-painter and art critic, John Deffett Francis, from 1876 to 1881, to receive whose first gift the library was established in 1876. It also contains a complete set of the patent office publications.

The grammar school founded in 1682 by Hugh Gore (1613–1691), bishop of Waterford, is now carried on by the town council under the Welsh Intermediate Education Act of 1889, and there is a similar school for girls. The technical college is also carried on by the town council, the chief features of its curriculum being chemistry, metallurgy and engineering. A training college for school-mistresses, established by the British and Foreign School Society in 1872, was transferred to the town council in 1908.

The other public buildings of the town include the gildhall and law courts, in the Italian style with Corinthian pillars and pilasters, built in 1847 and internally remodelled in 1901; a prison (1829); a fine market hall (1830), rebuilt in 1897; a cattle market and abattoirs (1869); the Albert Hall for concerts and public meetings (1864); the Royal Metal Exchange (1897); harbour trust offices (1904); a central post office (1901) and two theatres. The benevolent institutions include the general hospital, founded in 1817, removed to the present site in 1867, extended by the addition of two wings in 1878 and of an eye department in 1890; a convalescent home for twenty patients from the hospital only (1903); the Royal Cambrian Institution for the Deaf and Dumb, established in 1847 at Aberystwyth, removed to Swansea in 1850, and several times enlarged, so as to have at present accommodation for ninety-eight pupils; the Swansea and South Wales Institution for the Blind, established in 1865 and now under the Board of Education; the Swansea and South Wales Nursing Institute (1873), providing a home for nurses in the intervals of their employment; a nursing institution (1902) for nursing the sick poor in their own homes, affiliated with the Queen's Jubilee Institute of London; the Sailors' Home (1864); a Sailors' Rest (1885); and a Mission to Seamen's Institute (1904).

The town possesses 103 acres of parks and open spaces, the chief being Llewelyn Park of 42 acres in the north of the town near Morriston, Victoria Park (16 acres) and recreation ground (8 acres) abutting on the sands in the west, with the privately owned football field between them, Cwmdonkin (13 acres) commanding a fine panoramic view of the bay, and Brynmill (9 acres) with a disused reservoir constructed in 1837 and now converted into an ornamental lake. Other features of these parks are a small botanical garden in Cwmdonkin, a good collection of waterfowl in Brynmill, and a small aviary of the rarer British birds in Victoria Park, which also has a meteorological station in connexion with the meteorological office, and a statue of Mr William Thomas of Lan erected in 1905 in appreciation of the work done by him in preserving and obtaining "open spaces" for Swansea. In the town itself there are statues of J. Henry Vivian and of his son Sir Henry Hussey Vivian (created Lord Swansea in 1893) each in his turn the "copper king." The corporation owns about 645 acres of land within the limits of the ancient borough. This consists mainly of land acquired under an Inclosure Act of 1761, but a small part is surplus land acquired in 1876–1879 in connexion with an improvement scheme for clearing a large insanitary area in the centre of the town.

The town is lighted with gas supplied by a gas company first incorporated in 1830 and by electricity supplied by the corporation. There is a good system of electrically worked tramways, $5\frac{1}{2}$ m. being owned by a company and nearly 6 m. by the corporation, but the whole worked by the company. The town obtains its chief supply of water from moorlands situated on the Old Red Sandstone formation in the valley of the Cray, a tributary of the Usk in Breconshire where a reservoir of 1,000,000,000 gallons capacity has been constructed at a cost of £547,759, under parliamentary powers obtained in 1892, 1902 and 1905. The water is brought to the town in a conduit consisting of $23\frac{1}{4}$ m. of iron pipes and 3 m. of tunnel into a service reservoir of 3,000,000 gallons capacity made on the Town Hill at an elevation of 580 ft. above sea-level. There is a further supply obtained from three reservoirs of a combined capacity of 513,000,000, constructed in 1866, 1874 and 1889 respectively in the Lliw and adjoining valleys, in the drainage area of the Loughor, about 10 m. to the north of Swansea.

Harbour and Commerce.—Swansea owes its commercial prosperity to its great natural advantages as a harbour and its situation within the South Wales coal basin, for the anthracite portion of which it is the natural port of shipment. It is the most westerly port of the Bristol Channel and the nearest to the open sea, only 35 m. from the natural harbour of refuge at Lundy, and there is sheltered anchorage under the Mumbles Head at all states of the tide.

The modern development of the port dates from about the middle of the 18th century when coal began to be extensively worked at Llansamlet and copper smelting (begun at Swansea in 1717, though at Neath it dated from 1584) assumed large proportions. The coal was conveyed to the works and for shipment to a wharf on the east bank, on the backs of mules and somewhat later by means of a private canal. The common quay was on the west bank; all ships coming in had to lie in the river bed or in a natural tidal basin known as Fabian's Bay, on the east. Under an act of 1791 harbour trustees were appointed who cleared and deepened the river bed and built a long pier on either side of it; in 1796 the approach to the port was made safer by means of an improved light on Mumbles Head. A canal connecting the tidal part of the river Neath with the mouth of the Tawè, made in 1789, was in 1824 connected with the Vale of Neath canal by means of an aqueduct across the Neath river, when also a small dock, Port Tennant (so named after its owner) or Salthouse Dock, was made near the east pier, and this continued to be used till 1880. Meanwhile in 1798 the whole coalfield of the Swansea Valley was connected with the port by a canal $16\frac{1}{2}$ m. long (acquired by the Great Western railway in 1872). In 1851 the river was diverted eastward into a new channel (called the New Cut) and its old channel was locked and floated, thereby forming the North Dock with an area of $11\frac{1}{2}$ acres and a half-tide basin 500 yards long covering $2\frac{1}{2}$ acres. The Swansea Valley canal has a connecting lock with this dock, and on the island between the dock and the New Cut are patent fuel works, copper ore yards and other mineral sheds and large grain stores and flour mills. The South Dock, begun in 1847 under powers obtained that year by a private company, transferred in 1857 to the harbour trustees and opened in 1859, is mainly used for shipping coal and for discharging timber and fish. Lying parallel to the sea front and to the west of the entrance channel from which it runs at right angles, it has an area of 13 acres with a half-tide basin of 4 acres and a lock 300 ft. long by 60 ft. wide. The next development was on the east side of the river where the natural inlet of Fabian's Bay, inside the harbour mouth, was utilized for the construction of the Prince of Wales's Dock (authorized 1874, opened October 1881, extension opened March 1898). Its total area is 27 acres, its quays are nearly 7000 ft. long, and it is connected with the Tennant canal. The very rapid increase in the demand for anthracite coal (for the shipment of which Swansea has practically a monopoly) soon necessitated still further accommodation and in July 1904 was begun the King's Dock, which lies farther east and has an entrance direct from the bay. By means of the embankment made in connexion with it, 400 acres were reclaimed from the sea. It has an area of 68 acres, its lock measures 875 ft. by 90 ft. and its quays 10,550 ft. long, and it has a depth of 32 ft. of water, or inner cill. The total dock area of Swansea has thus been increased to about 147 acres with a total length of quays exceeding 3 m. The harbour docks and adjacent railways (which exceed 20 m.) are owned and administered by a harbour trust of 26 members, of whom one is the owner of the Briton Ferry estate (Earl Jersey), 4 represent the lord of the seigniory of Gower (the duke of Beaufort), 12 are proprietary members and 9 are elected annually by the corporation of Swansea. The trustees are conservators of the river Tawè and parts of Swansea Bay, and the pilotage and lighthouse authority of the district. They were incorporated by the Harbour Act of 1854. There are 9 private graving docks.

The total exports (foreign and coastwise) from Swansea during 1907 amounted to 4,825,898 tons, of which coal and coke made up 3,655,050 tons; patent fuel, 679,002 tons; tin, terne and black plates, 348,240 tons; iron and steel and their manufactures, 38,438 tons; various chemicals (mostly the by-products of the metal industries), 37,100 tons; copper, zinc and silver, 22,633 tons. Its imports during the same year amounted to 899,201 tons, including 172,319 tons of grain and other agricultural produce, 156,620 tons of firewood, 145,255 tons of pig-iron and manufactured iron and steel, 47,201 tons of iron ore, 121,168 tons of copper, silver, lead, tin and nickel with their ores and alloys, 63,009 tons of zinc, its ores and alloys, 41,029 tons of sulphur ore, phosphates and other raw material for the chemical trade. The town (which is often called "the metallurgical capital of Wales") is the chief seat of the copper, spelter, tin-plate and patent fuel industries, and has within a compass of 4 m. over 100 different works of 36 varieties (exclusive of collieries) for the treatment or manufacture of copper, gold, silver, lead, sulphate of copper, spelter, tinplates, steel and iron, nickel and cobalt, yellow metal, sulphuric acid, hydrochloric acid, creosote, alkali, galvanized sheets, patent fuel as well as engineering works, iron foundries, large flour and provender mills, fuse works and brick works. Copper smelting, which during most of the 19th century was the chief industry, has not maintained its relative importance, though Swansea is still the chief seat of the trade, but three-fourths of the tinplates manufactured in Great Britain and nineteen-twentieths of the spelter or zinc are made in the Swansea district, and its tube works are also the largest in the kingdom. While the bulk of the coal is sent to France and the Mediterranean ports, an increasing quantity of anthracite is shipped to Germany, and, in sailing vessels to the Pacific ports of America, patent fuel is largely sent to South America, whence return cargoes of mineral ores and grain are obtained, while Germany, France, Italy, Rumania, the United States and the Far East are the chief customers for tinplates. Over one hundred fishing-smacks and trawlers usually land their catches at the south dock, where there is a flourishing fish-market. There is also a large ice factory.

From 1535 to 1832 (with the exception of 1658–1659) Swansea was associated with the other boroughs of Glamorgan in sending one representative to Parliament. In 1658 Cromwell gave the town the right of separately returning a member of its own, but this right lapsed with the Restoration. In 1832 St John's, St Thomas and parts of the parishes of Llansamlet and Llangyfelach were added to the parliamentary borough of Swansea, to which along with the boroughs of Neath, Aberavon, Kenfig and Loughor a separate representative was given. In 1836 the municipal borough was made coextensive with the parliamentary borough and continued so till 1868, when some further small additions were made to the latter, with which the municipal borough was once more made co-extensive in 1889. Meanwhile in 1885 the parliamentary constituency was made into two divisions with a member each, namely Swansea Town consisting of the original borough with St Thomas's, and Swansea District consisting of the remainder of the borough with the four contributory boroughs. In 1888 Swansea was made a county borough and in 1900 the various parishes constituting it were consolidated into the civil parish of Swansea. Its total area is 5194 acres. The corporation consists of 10 aldermen and 30 councillors. The assizes and quarter sessions for Glamorgan are held at Swansea alternately with Cardiff. The borough has a separate commission of the peace, and, since 1891, a court of quarter sessions.

The population of the old borough was 6099 in 1801 and 13,256 in 1831; after the first extension it amounted to 24,604 in 1841. The population in 1901 was 94,537. Of those who were three years of age and upwards, nearly 67% were returned as speaking English only, 29% as speaking both English and Welsh, and $3\frac{1}{2}$% as speaking Welsh only.

History.—No traces of any Roman settlement have been discovered at Swansea, though there seems to have been a small one at Oystermouth, 5 m. to the south, and the *Via Julia* from Nidum (Neath) to Loughor probably passed through the northern part of the present borough where a large quantity of Roman coins was found in 1835. The name Swansea stands for Sweyn's "ey" or inlet, and may have been derived from King Sweyn Forkbeard, who certainly visited the Bristol Channel and may have established a small settlement at the estuary of the Tawe. The earliest known form of the name is Sweynesse, which occurs in a charter granted by William earl of Warwick some time previous to 1184; in King John's charter (1215) it appears as Sweyneshe, and in the town seal, the origin of which is supposed to date from about the same period, it is given as "Sweyse." An attempt has been made to derive the name from Sein Henydd, the Welsh name of a Gower castle which has been plausibly identified with the first castle built at Swansea, but that derivation is etymologically impossible. The Welsh name, Aber Tawy, first appears in Welsh poems of the beginning of the 13th century. The town grew up round the castle which Henry de Beauchamp (or Beaumont) on his conquest of Gower about 1099, built on the west bank of the river. The castle passed with the lordship or seigniory of Gower, of which it was the *caput*, into the hands of the De Braose family in 1203 (by grant from King John) and eventually it came by marriage to the Somersets and is still held by the dukes of Beaufort, whose title of barons de Gower dates from 1506. The castle was frequently attacked and on several occasions more or less demolished, in the 12th and 13th centuries by the Welsh under the princes of Dynevor. It was visited by King John in 1210 and probably by Edward II. in 1326, for, after his capture, the chancery rolls were found deposited in the castle and were thence removed to Hereford. It was finally destroyed by Glendower, was a "ruinous building" when seen by Leland (1536) and has since wholly disappeared. In the Civil War the town was royalist till the autumn of 1645 when Colonel Philip Jones, a native of the adjoining parish of Llangyfelach and subsequently a member of Cromwell's upper house, was made its governor. Cromwell stayed in the town in May 1648, and July 1649, on his way to Pembroke and Ireland respectively, and later showed it exceptional favour by giving it a liberal charter and parliamentary representation.

The town claimed to be a borough by prescription, for its only known charters of incorporation are those of Cromwell and James II., which were never acted upon. It probably received its first grant of municipal privileges from William 3rd earl of Warwick some time before 1184. By a charter of 1215 (confirmed by Henry II. in 1234, by Edward II. in 1312 and Edward III. in 1332), John himself granted the burgesses the right of trading, free of all customs due, throughout the whole kingdom (except in London), a right which was previously limited to the seigniory. By 1305 the burgesses had become so powerful as to wring a most liberal grant of privileges from their then seigneur William de Braose (fourth in descent from his namesake to whom Gower was granted by King John in 1203), and he bound himself to pay £500 to the king and 500 marks to any burgess in the event of his infringing any of the rights contained in it. By this charter the burgesses acquired the right of nominating annually two of their number for the office of portreeve so that the lord's steward might select one of them to exercise the office, an arrangement which continued till 1835; the bailiff's functions were defined and curtailed, and the lord's chancery was to be continually kept open for all requiring writs, and in Gower—not wherever the lord might happen to be. A patent of murage and pavage—from which it may probably be inferred that Swansea was a walled town—was granted by Edward II. in 1317 and another by Edward III. in 1338. Cromwell's charter of 1655, though reciting that "time out of mind" Swansea had been "a town corporate," incorporated it anew, and changed the title of portreeve into mayor, in whom, with twelve aldermen and twelve capital burgesses, it vested the government of the town. The mayor, ex-mayor and one selected alderman were to be justices of the peace with exclusive jurisdiction and the mayor was the coroner. Four annual fairs were appointed, namely on the 8th of May, 2nd of July, 15th of August and 8th of October—the first, however, being the only new one. In 1658 the protector by another charter granted the town independent representation in parliament. At the Restoration, Cromwell's charters lapsed, but in 1685 James II. granted another charter which contained the arbitrary proviso that the king by order in council might remove any officer or members of the corporation. This charter was not adopted by the burgesses.

De Braose's charter of 1305 bears some evidence to the importance of the shipping of Swansea even at that date, for by it there was granted or confirmed to the burgesses the right to take from the lord's woods sufficient timber to make four great ships at a time and as many small vessels as they wished. Coal was even then worked in the district. Cromwell in his charter of 1655 recognized Swansea as "an ancient port town and populous, situate on the sea coast towards France convenient for shipping and resisting foreign invasions." Its status was only that of a "creek" in the port of Cardiff till 1685, when it was made an independent port with jurisdiction over Newton (now Porthcawl), Neath or Briton Ferry and South Burry, its limits being defined in 1847 as extending from Nash Point on the east to Whitford Point on the west, but in 1904 Port Talbot, which was included in this area, was made into a separate port.

From about 1768 to 1850 Swansea had a somewhat famous pottery. Beginning with earthenware which twenty years later was improved into "opaque china," it produced from 1814 to 1823 superior porcelain which was beautifully decorated with landscapes, birds, butterflies and flowers and is much prized by connoisseurs. During a short period (1845–1850) an imitation of Etruscan ware was also produced with figures of rich red colour over a body of black.

Grant-Francis, *Charters Granted to Swansea* (1867), and *The Smelting of Copper in the Swansea District* (2nd ed., 1881); S. C. Gamwell, *A Guide to Swansea and District* (1880); Lieut.-Colonel W. Ll. Morgan, R.E., *An Antiquarian Survey of East Gower*. (D. Ll. T.)

SWANWICK, ANNA (1813–1899), English writer and philanthropist, was the youngest daughter of John Swanwick of Liverpool, and was born on the 22nd of June 1813. She was educated partly at home and partly at one of the fashionable boarding-schools of the day, where she received the usual education of accomplishments. Dissatisfied with her own intellectual attainments she went in 1839 to Berlin, where she took lessons in German, Greek and Hebrew. On her return to London she continued these pursuits, aloug with the study of mathematics. In 1843 appeared her first volume of translations, *Selections from the Dramas of Goethe and Schiller*. In 1847 she published a translation of Schiller's *Jungfrau von Orleans;* this was followed in 1850 by *Faust*, *Tasso*, *Iphigenie* and *Egmont*. In 1878 she published a complete translation of both parts of *Faust*, which appeared with Retsch's illustrations. It passed through several editions, was included in Bohn's series of translations, and ranks as a standard work. It was at the suggestion of Baron Bunsen that she first tried her hand at translation from the Greek. In 1865 she published a blank verse translation of Aeschylus's *Trilogy*, and in 1873, a complete edition of Aeschylus, which appeared with Flaxman's illustrations. Miss Swanwick is chiefly known by her translations, but she also published some original work. In 1886 appeared *Books, our Best Friends and Deadliest Foes*; in 1888, *An Utopian Dream and How it may be Realized*; in 1892, *Poets, the Interpreters of their Age*; and in 1894, *Evolution and the Religion of the Future*. Miss Swanwick was interested in many of the social and philanthropic movements of her day. In 1861 she signed John Stuart Mill's petition to parliament for the political enfranchisement of women. She helped in the higher education movement, took part in the foundation of Queen's and Bedford Colleges, and continued to take a sympathetic interest in the movement which led to the opening of the universities to women. Her work was acknowledged by the university of Aberdeen, which bestowed on her the degree of LL.D. She died in November 1899.

See *Memoir*, by Miss Bruce (1904).

SWARTZ, OLOF (1760–1818), Swedish botanist, was born in 1760. He commenced his botanical studies in Upsala, under

Linnaeus and Thunberg, and began early to make excursions. He made a voyage to America in 1783, visited England in 1788, returned to Sweden in 1789, and was made professor of natural history in Stockholm. He was the author of many systematic works, and largely extended our knowledge of both flowering plants and cryptogams. He died in 1818.

SWAT, a tract on the Peshawar border of the North-West Frontier Province of India, consisting of the valley of the Swat river above its confluence with the Panjkora. This valley is some 70 m. long, varying from 10 m. to a few hundred yards in breadth; it is intersected by ravines and glens, which bring down the drainage of the ranges on either side. Only that portion of the valley which lies beyond the Peshawar frontier hills, and which is reached by the Malakand, the Shahkot and other passes from the south, is Swat. To the east are the independent hill tracts of Kohistan and Buner, all bordering the Indus, and to the west are Dir and Bajour.

The Swat river rises among snow mountains in the Kohistan, not far from the source of the Gilgit river. After flowing due south for nearly 70 m., it turns to the west and is joined by the Panjkora. It then passes through the Mohmand country, and on entering Peshawar district spreads out to the south-east in many channels which ultimately fall into the Kabul river. Total length about 400 m. In British territory its waters have been utilised by a series of canals to irrigate an area of about 160,000 acres; and the system is now being extended by means of a tunnel through the Malakand range, which will tap the river much higher up.

Swat was better known to the ancients, and to the warriors of Baber's time, than it was to us until the frontier risings of 1895–97 gave British surveyors the opportunity of visiting the country. The ancient name of the river was Suastos, and that of the Panjkora was Ghoura, under which names they figure in the history of Alexander's campaign. The site of the city Massaga, the capital of the Assakeni, is supposed to be near the modern Manglaur. But since the adoption of the Khyber as the main high road from Kabul to India the Swat routes had passed into oblivion. Only the lower portion of the Swat valley, where the river intervenes between Malakand and the passes leading to Dir from the Panjkora, is of military significance. The upper valley is closely gripped between mountain spurs stretching southwards from the Hindu Koh, rising to 15,000 ft. on one side and 19,000 ft. on the other, leaving but a narrow space between their rugged summits and the banks of the river. The valley, narrow though it is, and traversed by the worst conceivable type of hill tracks, contains many villages or hamlets, and is pretty thickly populated. The district has come into prominence of recent years, on account of its lying on the direct road to Chitral.

The Swatis are a clan of Yusafzai Pathans numbering 40,000 fighting men but are of weakly and thin physique, due to the malaria with which the valley is saturated. They are divided into three main clans, the Baizais, Ranizais and Khwazozais. They had not much name for valour, but they opposed a stout resistance to Sir Robert Low's advance over the Malakand Pass in 1895 to the relief of Chitral; and again in 1897, under the influence of fanaticism, they showed desperate bravery in the attack on the Malakand Fort and Chakdara. They are all Suni Mahommedans, and have earned the reputation of being the most bigoted of all the Afghan tribes. For many years they were under the religious dominance of the Akhund of Swat, Abdul Ghafur, who, born in 1794, obtained ascendancy by means of his ascetic practices, ruled practically undisputed in Swat for the last 30 years of his life, and died in 1877. The Akhund, after his experience of the British strength in the Umbeyla Campaign of 1863, always exerted his influence in favour of peace with the British government, though in his earlier days he was sometimes troublesome. He was succeeded by his son Mian Gul, who never possessed the same influence as his father.

SWATOW (also *Shan'tow*), a port of China, in the province of Kwang-tung, opened to foreign trade in 1869. The population is upwards of 60,000. The town is situated at the mouth of the main branch of the river Han, which 30 miles inland flows past the great city of Ch'aochow Fu or Tai-chu (Tie-chu), while the surrounding country is more populous and full of towns and villages than any other part of the province. The climate is good, but being situated at the southern end of the Formosa Strait the town is exposed to the full force of the typhoons, and much destruction is occasionally wrought. English merchants settled on Double Island in the river as early as 1856; but the city, which is built on ground but recently recovered from the sea, was formerly a mere fishing village. The trade of the port has rapidly increased. In 1869 the total value of the trade was £4,800,000, in 1884 £5,519,772, and in 1904 £7,063,579. The surrounding country is a great sugar-cane district producing annually about 2,400,000 cwt. of sugar, and there is an extensive refinery in the town employing upwards of 600 workmen and possessing a reservoir for 7,000,000 gallons of water. Next in value comes the manufacture of bean-cake, which is also imported in large quantities from Niu-chwang, Chifu, Shanghai, Amoy and Hong-Kong. Among the leading exports are tea (since about 1872); grass-cloth, manufactured at Swatow from so-called Taiwan hemp (the fibre of the *Boehmeria nivea* from Formosa); pine-apple cloth, manufactured in the villages about Chieh-Yang (a town 22 m. distant); oranges, for which the district is famous; cheap fans; and pewter, iron and tin wares. Swatow is also a great emigration port and was the scene of many kidnapping adventures on the part of foreigners in the early days. Their outrages gave rise to much hostile feeling towards foreigners who were not allowed to enter the city of Ch'aochow Fu until the year 1861. Of the whole foreign trade of the port upwards of 83% is in British bottoms, the trade with Hong-Kong being of especial importance.

About 1865 the whole Swatow district was still divided into a number of "independent townships, each ruled by its own head-men," and the population was described in the official gazetteer, as "generally rebellious and wicked in the highest degree." Mr Forrest, British consular agent, relates that in that year he was witness to the preparations for a fight between the people living on the opposite sides of the estuary, which was only prevented by a British war-vessel. The T'aip'ings swept over the country, and by their ravages and plundering did much to tame the independence of the clans. The punishment inflicted in 1869 by Commander Jones on the inhabitants of Otingpui (Ou-ting-pei), about 8 m. from Swatow, for the attack they had made on the boats of H.M.S. "Cockchafer," showed the Chinese authorities that such piratical villages were not so strong as had been supposed. General Fang (a native of Ch'aochow Fu) was sent to reduce the district to order, and he carried out his instructions with remorseless rigour.

SWAZILAND (native name Pungwane), a country of British South Africa bounded S., W. and N. by the Transvaal, E. by the Portuguese possessions at Delagoa Bay and the Ingwavuma division of Zululand. It lies between the Drakensberg and Lebombo Mountains and is separated from the Indian Ocean by low land varying in width from 30 to 50 m. It has an area of 6536 sq. m. (being somewhat larger than Yorkshire) and a population (1904), of 85,484, of whom 898 were whites. The natives are nearly all Ama-Swazi Bantus, commonly called Swazis, and are closely allied to the Zulus.

Spurs from the Drakensberg occupy a large part of the country, which may be divided into three parallel belts running north and south. The western belt has an average altitude of about 4500 ft., and is known as the high veld. It is succeeded by the middle veld—not more than 2500 ft. above the sea, and that by the low veld—1000 ft. high, which reaches to the foot of the Lebombo Mountains. These are flat-topped, nowhere higher than 2000 ft. The country is well watered by numerous rivers, all of which discharge into Delagoa Bay. The central and southern parts are drained by the Usutu and other tributaries of the Maputa; the northern region by the Komati (*q.v.*) and the Umbelozi. The Umbelozi has two chief headstreams, the Black and the White Umbelozi, the White branch being the more southerly. The climate is warm but healthy save in some of the river valleys. The flora and fauna differ in no essential respects from the corresponding regions of the TRANSVAAL and ZULULAND (see those articles).

Towns and Communications.—The seat of the administration is Embabaan (Mbabane), a town on a northern tributary of the Usutu 4300 ft. above the sea, 40 m. south of Barberton and 180 m. east of Johannesburg. It replaced (1904) the former capital of Bremersdorp situated in the middle veld 23 m. south-east of Embabaan, and destroyed by Boer forces during the war of 1899–1902. Pigg's Peak and Forbes Reef are mining settlements in northern Swaziland. Hlatikulu, the chief place in southern Swaziland, is built on a plateau about 3000 ft. above the sea. Zombodi, the principal native kraal, lies about 18 m. east of Embabaan.

A railway from Lourenço Marques, 47 m. long, runs through Portuguese territory to the Swaziland border at Umbelozi Poort. This line is the eastern link in the direct railway connexion designed between Johannesburg and Delagoa Bay. From Johannesburg the line runs eastward past Springs and had reached Breyten (143 m.) in 1907. A number of good roads have been constructed. There is telegraphic connexion with the Transvaal.

Industries and Trade.—The soil is generally fertile. On the high veld, where green herbage is found all the year round, large numbers of sheep and cattle are pastured. This region serves as a winter grazing ground for sheep from the Transvaal. The middle veld is suitable for grain crops as well as bananas, sugar, coffee, tea and other semi-tropical produce. Millet, maize, pumpkins and ground-nuts are extensively cultivated. On the low veld cotton is grown. Some species of the cotton plant are indigenous.

Besides agriculture the only considerable industries are gold, tin and coal mining. The goldfields, situated in the north-western part of the country, are a continuation of the De Kaap (Barberton) fields. The auriferous region is stated to be about 25 sq. m. in extent. Up to the outbreak of the Anglo-Boer War in 1899 the value of the gold exported from Swaziland was about £350,000. Gold mining re-started on a small scale in 1904. The output for 1906–1908 was valued at £40,000. Alluvial tin mining is carried on successfully in the neighbourhood of Embadaan, cassiterite to the value of £46,000 being exported in 1905–1907. The output for 1908–1909 was valued at £36,000. Anthracite coal of a good quality is found over a large area of the low veld. Copper is also found. All mining is carried on under concessions. Imports are chiefly food-stuffs and cotton goods; they were valued in 1906 at £38,000 and in 1909 at £47,000. Up to 1906 no statistics of the trade of the country were kept. Trade is with the Transvaal and Delagoa Bay. The abolition of monopolies in 1904 (see below *History*) gave an impetus to trade. Up to that date some £4,000,000 of foreign capital had been sunk in the country with very little return. A large number of Swazis find employment in the Rand gold mines.

Administration, &c.—Swaziland forms a crown colony under the government of the High Commissioner for South Africa. It is administered by a resident commissioner. Legislation is by ordinance. Roman-Dutch common law prevails except when modified by statute, the laws of the Transvaal being in force as far as applicable to the country. Native laws and customs are generally respected and the chiefs exercise civil jurisdiction over their tribesmen, subject to appeal to the resident commissioner's court. There is a special court to deal with serious civil and criminal cases in which Europeans are concerned. Order is maintained by a special police force. Education is mainly dependent on the efforts of missionary societies, but the administration has a few schools.

Revenue is derived chiefly from a poll-tax on natives of £1 per annum, concession rents, royalties and customs. For the period 1904–1909 the revenue—apart from loans—was about £40,000 a year, the normal expenditure being approximately the same amount. Since 1904 considerable sums (*e.g.* £49,000 in 1909) have been spent by the administration on the expropriation of monopolies. Swaziland is a member of the South African Customs Union (see SOUTH AFRICA).

History.—Ama-Swazi tribes are believed to have occupied the country now known as Swaziland from the period of the invasion of South East Africa by the Bantu peoples. They were formerly called Ba-Rapuza or Barabuza after a chief under whom in the 18th century they acquired homogeneity. In the early part of the 19th century they fell under the dominion of the newly constituted Zulu nation. In 1843, the year in which the British annexed Natal and with it a part of the country hitherto ruled by the Zulus, the Barabuza, under a chief named Swazi, took advantage of the comparative weakness of the Zulu power, achieved independence and founded the present state. According to Kaffir custom they adopted the name of their deliverer. The Boers of the Transvaal were then beginning to occupy the regions adjacent to Swaziland and in 1855 the Swazis in order to get a strip of territory between themselves and the Zulus, whose power they still dreaded, ceded to the Boers the narrow strip of land north of the Pongola river now known as the Piet Retief district. The Zulus under Cetywayo claimed the ceded district as theirs and the Swazis as their subjects and for over ten years no white farmers were able to settle in the district. With the Boers the Swazis remained on friendly terms and this friendship was extended to the British on the occupation of the Transvaal in 1877. In 1879 they joined the British in the attack on the Bapedi chief Sikukuni, whom they looked upon as an ally of the Zulus.

They captured from Sikukuni certain "rain medicine," the possession of which has since greatly increased the prestige of the paramount chief of the Swazis among the Kaffirs of South Africa. On the retrocession of the Transvaal in 1881 the independence of the Swazis was recognized by the Boers and the Pretoria convention of that year defined the boundaries of the country. By the London convention of 1884 the Transvaal again recognized the independence of Swaziland. Immediately afterwards, however, the Boers began a series of efforts to obtain control of the country. In 1886 the governor of Natal received a paper from Umbandine (Mbandini), the paramount chief of the Swazis, stating that Piet Joubert had called on him and requested him to sign a paper saying that "he and all the Swazis agreed to go over and recognize the authority of the Boer government, and have nothing more to do with the English." On his refusal the Boers replied to him, "Why do you refuse to sign the paper? You know we defeated the English at Majuba." The Boers further added that if the Swazis were relying on the British, they were leaning on a broken reed, and would find themselves left in the lurch. Umbandine followed up this communication with a request for British protection, but without result. Later on, in 1887, both Boers and gold prospectors of all nationalities were overrunning his country, and Umbandine asked for a British resident. This request was also refused. The Boers now determined to adopt towards Swaziland the policy which had proved so successful in Zululand. A colony of Boers settled within the Swazi territories and proclaimed "The Little Free State." Umbandine was then at length induced to ask the Transvaal for annexation. The Transvaal applied in 1889 to Great Britain for permission to accede to this request, but the British government replied that the only intervention to which they would consent must be a dual one. Consequently a joint commission was appointed to visit Swaziland and report on the condition of things there. Sir Francis de Winton, the British commissioner, who was accompanied by Generals Joubert and Smit on behalf of the Transvaal, reported that Umbandine had already granted concessions, such as "postal, telegraphic, banking, customs," &c., to the Transvaal, and concessions of land mining and grazing rights to various adventurers. Umbandine had in short granted concessions of every conceivable character, including exemption from taxation. A charter of self-government had also been granted (1888) to the whites in the country. In the circumstances de Winton considered a British protectorate inadvisable and impracticable. A dual control was arranged in 1890, but the convention then signed proved abortive owing to the objection of the Transvaal to join the South African Customs Union. In 1893 a further conference on the Swazi question took place between Sir Henry Loch, high commissioner for South Africa, and President Kruger, the result of which was that the administration of Swaziland, with certain reservations as to the rights of the natives, was made over to the South African Republic. In the following year six Swazi envoys visited England for the purpose of asking Queen Victoria to take Swaziland under her protection. In view, however, of the arrangement come to, this petition had to be refused. In 1894 a convention was signed between Great Britain and the Transvaal, and the Boers, in spite of the Swazi opposition, assumed administration of the country. The Boers' object in intriguing to acquire Swaziland was not merely that of obtaining that country. They desired also to annex the coast lands to its east and thus obtain—at Kosi Bay—a seaport of their own. This object they might have attained if they had agreed to de Winton's proposals, but Great Britain in view of the increasingly hostile attitude assumed by the Transvaal government now intervened and by annexing in 1895 Amatongaland, the region in question, blocked the Boers' further progress towards the sea (see SOUTH AFRICA: *History*).

Swaziland suffered during the struggle between the Transvaal and Great Britain as to its destiny. Umbandine died in 1889 and had various successors. Ubanu, installed by the Boers as paramount chief in 1894, was a sanguinary despot and was compelled to flee in 1898. The principal personage in the country after Umbandine's death was, however, his widow Naba Tsibeni, known to Europeans as the queen regent. She more than once appealed to the British to cause the Boers to respect the terms of the conventions, and before the outbreak of the Anglo-Boer war in 1899 she took the side of the British. On the annexation of the Transvaal in 1901 the queen regent asked that Swaziland might be annexed also. On the cessation of hostilities a British special commissioner was sent into the country—then in a condition bordering on anarchy—and a provisional administration established. In June 1903 an order in council formally conferred the government of the country on the governor of the Transvaal (then Lord Milner). Lord Milner visited Swaziland in July 1904 and denounced "the abominable network of concessions" in which the country was entangled. On the 3rd of October following the governor issued a proclamation providing further for the administration, and for the expropriation of the concessions other than those relating to land and minerals. In September 1906 Lord Selborne, who had succeeded Lord Milner, conferred with the queen regent and her councillors on questions specially affecting the natives. A lad named Sobhuza, born about 1898, was selected as paramount chief, Naba Tsibeni, his grandmother, being confirmed as regent during his minority. In December 1906 the control of Swaziland was severed from the governorship of the Transvaal and transferred to the High Commissioner for South Africa, and in March 1907 a resident commissioner was appointed. When the Union of South Africa was established in 1910, Swaziland, with other native territories, remained under direct Imperial control.

See A. M. Miller, "Swaziland," in *Journ. Roy. Col. Inst.* (1900), vol. xxxi., and "Swaziland: its agricultural and pastoral future," in *Transvaal Agricultural Journ.*, vol. iv. (1906); T. R. Jones, "Notes on the Geology of West Swaziland" in *Geol. Mag.* (1899), vol. vi. Colonial office reports on the country have been issued annually since 1908. Consult also the *Colonial Office List* issued yearly. In it are cited the Blue Books dealing with Swaziland. For history see also TRANSVAAL: *Bibliography*.

(A. P. H.; F. R. C.)

SWEARING (O. Eng. *swerian*, to swear, originally to speak aloud, cf. *andswerian*, to answer, Ger. *schwören*, Dan. *svaerge*, &c., all from root *swer-*, to make a sound, cf. "swarm," properly the buzzing of bees, Lat. *susurrus*), the affirmation or uttering of a solemn declaration with an appeal to the Deity, some holy personage or sacred object as confirmation, hence the act of declaring the truth of a statement upon oath (see OATH and EVIDENCE). The common use of the word is for the uttering of profane oaths or curses. In English law, while blasphemy (*q.v.*) was at common law an indictable offence, cursing or swearing was left to the ecclesiastical courts. The Profane Oaths Act 1745 inflicted a sliding scale of fines for the use of profane oaths according to the rank of the offender, 1s. for a common labourer, soldier or seaman, 2s. for everyone below the rank of gentleman and 5s. for those of or above that rank; procedure under this act is regulated by the Summary Jurisdiction Acts. By s. 8 of the Town Police Clauses Act 1847 the use of profane or obscene language is an offence punishable on summary conviction by a fine not exceeding 40s. or imprisonment not exceeding 14 days. The offence must be committed in a street and the act is confined to urban sanitary districts or to such rural districts to which s. 276 of the Public Health Act 1875 has extended it. By s. 12 of the Metropolitan Police Court Acts 1839 a similar offence is punishable in the metropolitan police area, and various districts have put in force by-laws for punishing swearing, cursing, or causing annoyance in public places. The restriction as to the place where the offence must be committed to be liable to punishment has led to the enforcement on occasions of the Profane Oaths Act, which applies to the whole of England and Wales and is not limited to cursing in the streets. It should not, however, apply to obscene language.

SWEATING-SICKNESS. A remarkable form of disease, not known in England before, attracted attention at the very beginning of the reign of Henry VII. It was known indeed a few days after the landing of Henry at Milford Haven on the 7th of August 1485, as there is clear evidence of its being spoken of before the battle of Bosworth on the 22nd of August. Soon after the arrival of Henry in London on the 28th of August it broke out in the capital, and caused great mortality. This alarming malady soon became known as the sweating-sickness. It was regarded as being quite distinct from the plague, the pestilential fever or other epidemics previously known, not only by the special symptom which gave it its name, but also by its extremely rapid and fatal course.

From 1485 nothing more was heard of it till 1507, when the second outbreak occurred, which was much less fatal than the first. In 1517 was a third and much more severe epidemic. In Oxford and Cambridge it was very fatal, as well as in other towns, where in some cases half the population are said to have perished. There is evidence of the disease having spread to Calais and Antwerp, but with these exceptions it was confined to England.

In 1528 the disease recurred for the fourth time, and with great severity. It first showed itself in London at the end of May, and speedily spread over the whole of England, though not into Scotland or Ireland. In London the mortality was very great; the court was broken up, and Henry VIII. left London, frequently changing his residence. The most remarkable fact about this epidemic is that it spread over the Continent, suddenly appearing at Hamburg, and spreading so rapidly that in a few weeks more than a thousand persons died. Thus was the terrible sweating-sickness started on a destructive course, during which it caused fearful mortality throughout eastern Europe. France, Italy and the southern countries were spared. It spread much in the same way as cholera, passing, in one direction, from north to south, arriving at Switzerland in December, in another northwards to Denmark, Sweden and Norway, also eastwards to Lithuania, Poland and Russia, and westwards to Flanders and Holland, unless indeed the epidemic, which declared itself simultaneously at Antwerp and Amsterdam on the morning of the 27th of September, came from England direct. In each place which it affected it prevailed for a short time only—generally not more than a fortnight. By the end of the year it had entirely disappeared, except in eastern Switzerland, where it lingered into the next year;[1] and the terrible "English sweat" has never appeared again, at least in the same form, on the Continent.

England was, however, destined to suffer from one more outbreak of the disease, which occurred in 1551, and with regard to this we have the great advantage of an account by an eye-witness, John Kaye or Caius, the eminent physician.

Symptoms.—The symptoms as described by Caius and others were as follows. The disease began very suddenly with a sense of apprehension, followed by cold shivers (sometimes very violent), giddiness, headache and severe pains in the neck, shoulders and limbs, with great prostration. After the cold stage, which might last from half-an-hour to three hours, followed the stage of heat and sweating. The characteristic sweat broke out suddenly, and, as it seemed to those accustomed to the disease, without any obvious cause. With the sweat, or after that was poured out, came a sense of heat, and with this headache and delirium, rapid pulse and intense thirst. Palpitation and pain in the heart were frequent symptoms. No eruption of any kind on the skin was generally observed; Caius makes no allusion to such a symptom. In the later stages there was either general prostration and collapse, or an irresistible tendency to sleep, which was thought to be fatal if the patient were permitted to give way to it. The malady was

[1] Guggenbühl, *Der englische Schweiss in der Schweiz* (Lichtensteig, 1838).

remarkably rapid in its course, being sometimes fatal even in two or three hours, and some patients died in less than that time. More commonly it was protracted to a period of twelve to twenty-four hours, beyond which it rarely lasted. Those who survived for twenty-four hours were considered safe.

The disease, unlike the plague, was not especially fatal to the poor, but rather, as Caius affirms, attacked the richer sort and those who were free livers according to the custom ol England in those days. "They which had this sweat sore with peril of death were either men of wealth, ease or welfare, or of the poorer sort, such as were idle persons, good ale drinkers and taverne haunters."

Causes.—Some attributed the disease to the English climate, its moisture and its fogs, or to the intemperate habits of the English people, and to the frightful want of cleanliness in their houses and surroundings which is noticed by Erasmus in a well-known passage, and about which Caius is equally explicit. But we must conclude that climate, season, and manner of life were not adequate, either separately or collectively, to produce the disease, though each may have acted sometimes as a predisposing cause. The sweating-sickness was in fact, to use modern language, a specific infective disease, in the same sense as plague, typhus, scarlatina or malaria.

The only disease of modern times which bears any resemblance to the sweating-sickness is that known as *miliary fever* ("Schweiss-friesel," "suette miliaire" or the "Picardy sweat"), a malady which has been repeatedly observed in France, Italy and southern Germany, but not in the United Kingdom. It is characterized by intense sweating, and occurs in limited epidemics, not lasting in each place more than a week or two (at least in an intense form). On the other hand, the attack lasts longer than the sweating-sickness did, is always accompanied by eruption of vesicles, and is not usually fatal. The first clearly described epidemic was in 1718 (though probably it existed before), and the last in 1861. Between these dates some one hundred and seventy-five epidemics have been counted in France alone.

Authorities.—For history see Bacon's *Life of Henry VII.*, and the chronicles of Grafton, Holinshed, Baker, Fabyan, &c. The only English medical account is that of John Caius, who wrote in English *A Boke or Counseill Against the Disease commonly called the Sweate, or Sweating Sicknesse* (London, 1552); and in Latin *De ephemera britannica* (Louvain, 1556; reprinted London, 1721). The English tract is reprinted in Babington's translation of Hecker's *Epidemics of the Middle Ages* (Syd. Soc., 1844). This also contains Hecker's valuable treatise on the English sweat, published in German (1834), and also printed in his *Volkskrankheiten des Mittelalters*, edited by Hirsch (Berlin, 1865). Grüner's *Scriptores de sudore anglico* (Jena, 1847), contains nearly all the original documents, including the two treatises of Caius. See also Hirsch, *Handbook of Geographical and Historical Pathology*, trans. by Creighton (New Syd. Soc., 1885).

SWEATING SYSTEM, a term loosely used in connexion with oppressive industrial conditions in certain trades. This "system" originated early in the 19th century, when it was known as "the contract system." Contractors supplying the government with clothing for the army and navy got the work done by giving it out to sub-contractors, who in some cases made the garments or boots themselves, with the assistance of other workmen, and in others sublet their sub-contracts to men who carried them out with similar help. Afterwards this plan was adopted in the manufacture of ready-made clothing for civilian use, and of "bespoke" garments (made to the order of the customer). Previously the practice had been for coats, &c., to be made up by workmen employed on the premises of the master tailor or working together in common workshops, but in either case directly employed by the master tailor. The new plan brought a large number of workpeople possessing little skill and belonging to a very needy class into competition with the regular craftsmen; and in consequence a fall in wages took place, which affected, to a greater or less extent, the whole body of workmen in the tailoring trade. The work was done in overcrowded and insanitary rooms, and the earnings of the workers were extremely low. In 1850 a vigorous agitation against "the sweating system" was commenced, based mainly upon a series of articles in the *Morning Chronicle*, which were followed by a pamphlet, *Cheap Clothes and Nasty*, written by Charles Kingsley under the name of "Parson Lot," and by his novel *Alton Locke*. Kingsley and his friends, the Christian Socialists, proposed to combat the evils of the sweating system by promoting the formation of co-operative workshops; and several experiments of this nature were made, which, however, met with little success. Except that in 1876–1877 the outcry against the sweating system was renewed (principally on the ground of the risk of infection from garments made up in insanitary surroundings), the matter attracted little public notice until 1887, when the system again came into prominence in connexion with the immigration of poor foreigners into East London, where large numbers of these people were employed in various trades, especially in the tailoring, boot-making, and cabinet-making industries, under conditions generally similar to those complained of in the earlier agitations. In 1888 a select committee of the House of Lords was appointed to inquire into the subject; and after a lengthy investigation—in the course of which evidence was given by 291 witnesses in relation to tailoring, boot-making, furriery, shirt-making, mantle-making, cabinet-making and upholstery, cutlery and hardware manufacture, chain and nail-making, military accoutrements, saddlery and harness-making, and dock labour—this committee presented its final report in April 1890. The committee found themselves unable to assign an exact meaning to the term "sweating," but enumerated the following conditions as those to which that name was applied: "(1) A rate of wages inadequate to the necessities of the workers or disproportionate to the work done; (2) excessive hours of labour; (3) the insanitary state of the houses in which the work is carried on." They stated that, "as a rule, the observations made with respect to sweating apply, in the main, to unskilled or only partially skilled workers, as the thoroughly skilled workers can almost always obtain adequate wages." With regard to the sweating system, the committee declared that this cannot be regarded as responsible for the industrial conditions described; for "the middleman is the consequence, not the cause of the evil; the instrument, not the hand which gives motion to the instrument, which does the mischief. Moreover, the middleman is found to be absent in many cases in which the evils complained of abound." While, on the one hand, we find, as pointed out by this committee, that "sweating" exists without the presence of the "middleman" (the fact being that many grossly underpaid workpeople are in the direct employment of large firms), it is, on the other hand, no less true that the "middleman" (*i.e.* subordinate employer) is common in numerous trades in which there is no trace of any such oppression of the workpeople employed by the sub-contractors as is denoted by the term "sweating." Thus, for example, in shipbuilding in many cases men work in squads, the leading workmen employing their own helpers; in the cotton trade the mule-minders engage and pay their own piecers, and the weavers their own tenters; in the manufactured-iron trade, in mining, &c., a good deal of work is done under sub-employers employing their own assistants, none of these sub-contractors being alleged to "sweat" their helpers. There is, in short, no system of employment which can properly be called "the sweating system." At the same time, wherever workers possessing a small degree of skill and deficient in organization are employed under a number of small masters, there "sweating" is likely to obtain.

The common idea that the "sweater" is an unscrupulous tyrant, who fulfils no useful function, and who makes enormous profits, has no counterpart in fact. Whatever may have been the case in earlier days, before the internecine competition of the "middlemen" had time to produce its inevitable effects upon the position of these sub-employers, it may now be considered to be beyond dispute that the small master ("sub-contractor," "garret master," "fogger," &c.) usually works at least as hard as his employés, and that his gains are, as a rule, no more than a fair return for the work which he performs—work which in many instances consists in doing some difficult part of the job, and in all cases in organizing the labour engaged. So far as concerns the "manufacturer," by whom the "sweater" is employed, and who is clearly the *causa causans* of "the sweating system," for him the practice of getting his work done in outside workshops is undoubtedly convenient, especially in localities where rent is high, because he is saved the expense of providing accommodation for those who do his work. He is also free from restrictions as to the subdivision of labour and the employment of a certain class of workpeople which the sentiment of the regular factory workers would impose upon him. The regular tailor, for example, thinks that no one who has not, by a lengthy period of tuition, acquired the capacity to make a coat "right out" ought to be allowed to enter the tailoring trade. But in the workshop of the sub-contractor the work is split up into fractions, each of which is soon learned, so that it becomes possible to introduce into the trade persons possessing no previous training, and generally willing to work for wages far lower than those to which the regular tailors consider themselves entitled, and which, so long as they are not exposed to the competition of these outsiders, they are usually able to secure. On the other hand, while it may suit the manufacturer, anxious to keep down the cost of production, to give his work out to middlemen, it is beyond question that any form of the "small master" system is necessarily liable to abuse in many directions. Among these small masters the eagerness to secure employment is usually so keen that the work is often taken at a price too low for it to be possible for these sub-employers to pay to their workpeople wages adequate to provide the reasonable requirements of working-class life. The workshops of the middlemen are scattered over large districts, and these little masters frequently move their business from one house to another. Both of these are circumstances which tend strongly to make efficient regulation by the factory and the sanitary inspectors very difficult. Not seldom, especially when trade is brisk, these work-places are overcrowded in a manner injurious to health, and in not a few cases their sanitary condition is defective. It will readily be understood that combination among the people employed in these numerous small isolated work-places is much less easy than among the compact bodies of workers employed in large factories, so that any attempt to resist oppressive conditions of employment by trade-union organization meets with serious obstacles. But perhaps the worst of all the features which this method of manufacture presents is the absence of motor power and machinery. The fact that a manufacturer has laid out a large sum in plant, thus entailing a heavy expenditure in "standing charges," necessarily induces him to do his best to make employment regular. In the little outside workshop, on the other hand, lengthy spells of enforced idleness are followed by short periods of most severe toil, during which the hours of daily labour are prolonged to an inhuman extent. At the same time, the workpeople employed in the ill-equipped workshop of the little master are competing with the much more efficient production of the factory provided with labour-saving machinery driven by steam or other mechanical power; and in many cases their only chance of retaining the work under these circumstances is to take it at starvation prices. But the progress of invention moves fast, and antiquated methods of production are gradually being abandoned. Already, in many of the trades in which the sweating system has hitherto largely prevailed, especially in the tailoring, the boot-making, the cabinet-making and the nail-making industries, the factory system is coming so far to the front in the race for cheapness of production that, although in certain industrial centres, in which the rents of factories are high and a specially abundant supply of needy and unskilled workpeople is available, a good deal of work is still given out to small outside masters, the proportion of the total output manufactured in this manner is day by day diminishing. (D. Sch.)

An endeavour has been made in the United Kingdom to combat legislatively the evils of sweating. The Trade Boards Act 1909 established trade boards for trades to which the act applied. The trades specified were ready-made and wholesale tailoring, the making of paper or chip boxes, machine-lace making and chain-making, but the board of trade was given power to apply the act under a provisional order to any other trade in which exceptionally low wages prevailed. The duties of the trade boards are to fix, subject to certain restrictions, minimum rates of wages for time-work for their trades, while they may also fix general minimum rates of wages for piece-work, and these rates may apply either universally to the trade, or to any special process in the work of the trade or to any special class of workers, or to any special area. The rates so fixed become obligatory by order of the board of trade upon the expiration of six months from the date when made by a trade board, but they may, in the meantime, have a limited operation (1) in the absence of a written agreement; (2) where an employer has given written notice to the board of trade that he is willing to pay them; and (3) in the case of contracts vith government departments and local authorities. If the minimum rate of wages has been made obligatory and an employer has been summarily convicted of not paying same, he is liable to a penalty of not exceeding £20 in respect of each offence and to a penalty of not exceeding £5 for each day on which the offence is continued after conviction. He may also be ordered to pay, in addition, a sum equal to the wages due. The trade boards consist of an equal number of representative members of employers and workers, together with appointed members whose number must be less than half the total of representative members. Trade boards may also establish district trade committees with a constitution similar to their own and may delegate to them their powers and duties under the act. Women are eligible for membership of trade boards or district committees indeed, in case of a trade board for a trade in which women are largely employed, at least one of the appointed members must be a woman.

SWEDEN [*Sverige*], a kingdom of northern Europe, occupying the eastern and larger part of the Scandinavian peninsula. It is bounded N.E. by Finland (Russian Empire), E. by the Gulf of Bothnia and the Baltic Sea, S.W. by the Cattegat and Skagerrack, and W. by Norway. It extends from 69° 3′ 21″ to 55° 20′ 18″ N., and from 11° 6′ 19″ E. on the south-west coast to 24° 9′ 11″ E. on the Finnish frontier, the extreme length being about 990 m., the extreme breadth (mainland) about 250 m., and the total area estimated at 173,547 sq. m. Out of a detailed total estimate of the boundary line at 6100 m., 4737 m. are coastal, the Norwegian frontier is 1030 m., and the Finnish 333 m.

Physical Features.—The backbone of the Scandinavian peninsula is a range, or series of masses, of mountains (in Swedish *Kölen*,[1] the keel) extending through nearly the whole length of the peninsula towards the western side. The eastern or Swedish flank has, therefore, the slighter slope. This range forms, in a measure, a natural boundary between Sweden and Norway from the extreme north to the north of Svealand, the central of the three main territorial divisions of Sweden (Norrland, Svealand and Götaland); though this boundary is not so well markd that the political frontier may follow it throughout. Sweden itself may be considered in four main physical divisions—the mountains and highland district, covering all Norrland and the western part of Svealand; the lowlands of central Sweden; the so-called Småland highlands, in the south and south-east; and the plains of Skåne, occupying the extreme southward projection of the peninsula.

Northern Highlands.

The first district, thus defined, is much the largest, and includes the greatest elevations in the country and the finest scenery. The highest mountains are found in the north, the bold peak of Kebnekaise reaching 7005 ft., Sarjektjåcko, 6972 ft., being the loftiest point of a magnificent group including the Sarjeksfjäll, Alkasfjäll and Partefjäll, which range from 6500 ft. upwards; and, farther south, Sulitelma, 6158 ft., long considered the highest point in Scandinavia. Elevation then decreases slightly, through Stuorevarre (5787 ft.) and Areskutan (4656 ft.), to the south of which the railway from Trondhjem in Norway into Sweden crosses the fine pass at Storlien. South of this again, before the main chain passes into Norway, are such heights as Helagsfjäll (5896 ft.) and Storsylen (5781 ft.); and a group of mountains in the northern part of the province of Dalecarlia (Dalarne), ranges from 3600 to 4500 ft. in height. The neighbourhood of Åreskutan and the Dalarne highlands, owing to the railway and the development of communications by steamer on the numerous lakes, are visited by considerable numbers of travellers, both Swedish and foreign, in summer; but the northern heights, crossed only by a few unfrequented tracks, are known to few, and to a considerable extent, indeed, have not been closely explored. From the scenic standpoint the relatively small elevation of these mountains finds compensation in the low snow-line, which ranges from about 3000 ft. in the north to 5500 ft. in the south of the region. All the higher parts are thus snow-clad; and glaciers, numerous in the north, occur as far south as the Helagsfjäll. The outline of the mountains is generally rounded, the rocks having been subjected to erosion from a very early geological age, but hard formations cause bold peaks at several points, as in Kebnekaise and the Sarjeksfjäll.

[1] In Swedish the definite article (masc. and fem. *en*, neut, *et*) is added as a suffix to the substantive (when there is no epithet). Geographical terms are similarly suffixed to names, thus *Dalelfven*, the river Dal. The commonest geographical terms are : ***elf***, ***ström***, river; ***sjö***, lake; ***ö***, island; ***holm***, small island; ***fjäll***, mountain, group or range; ***dal***, valley; ***vik***, bay. In Norrland the following terms are common: ***å***, river, often attached to the names of the large rivers, as Torneå, Luleå (although properly it means a smaller river than *elf*); the names of towns at their mouths always following this form; *träsk* (local, properly meaning marsh), *jaur* (Lapp), *afva*, lake (provincial Swedish, properly a kind of creek opening from a river). *Å* is pronounced *ō*.

Rivers of the North. From the spinal mountain range a series of large rivers run in a south-easterly direction to the Gulf of Bothnia. In their upper parts they drain great lakes which have resulted from the formation of morainic dams, and in some cases perhaps from the incidence of erratic upheaval of the land. All lie at elevations between 900 and 1300 ft. All are narrow in comparison with their length, which is not infrequently magnified to view when two lakes are connected by a very short stretch of running water with a navigable fall of a few feet, such as those between Hornafvan, Uddjaur and Storafvan on the Skellefte river. The following are the principal rivers from north to south: The Torne, which with its tributary the Muonio, forms the boundary with Finland, has a length of 227 m., and drains lake Torne (Torneträsk), the area of which is 126 sq. m. The Kalix is 208 m. in length. The Lule is formed of two branches, Stora and Lilla (Great and Little) Lule; the length of the main stream is 193 m. The Stora Lule branch drains the Langas and Stora Lule lakes (Langasjaur, Luleträsk), which have a length together exceeding 50 m., a fall between them of some 16 ft. and a total area of only 87 sq. m., as they are very narrow. Below Stora Lule lake the river forms the Harsprång (hare's leap; Njuommelsaska of the Lapps), the largest and one of the finest cataracts in Europe. The sheer fall is about 100 ft., and there is a further fall of 150 ft. in a series of tremendous rapids extending for 1¼ m. Farther up, at the head of Langasjaur, is the Stora Sjöfall (great lake fall; Lapp, Ätna Muorki Kartje), a fall of 130 ft. only less grand than the Harsprång. Both are situated in an almost uninhabited country and are rarely visited. Following the Pite river (191 m.), the Skellefte (205 m.) drains Hornafvan and Storafvan, with a fall of 20 ft., and an area together of 275 sq. m. Hornafvan is a straight and sombre trough, flanked by high hills of unbroken slope, but Storafvan and the intervening Uddjaur are broad, throwing off deep irregular inlets, and picturesquely studded with numerous islets. The Ume (237 m.) receives a tributary, the Vindel, of almost equal length, on the north bank some 20 m. from its mouth, and among several lakes drains Stor Uman (64 sq. m.). The further principal rivers of this region are the Ångerman (242 m.), Indal (196 m.), draining the large lakes Kallsjö and Storsjö, Ljusnan (230 m.), Dal and Klar. Of these the two last rise in the southernmost part of the mountain region described, but do not as a whole belong to the region under consideration. The Ångerman receives the waters of a wider system of streams and lakes than the rivers north of it, and has thus a drainage area of 12,591 sq. m., which is exceeded only by that of the Torne (16,690 sq. m.), the average of the remaining rivers named being about 7700 sq. m.

Beyond the Harsprång and the Stora Sjöfall the northern rivers do not generally form great falls, though many of the rapids are grand. The Indal, by changing its course in 1796 near Bispgården on the northern railway, has left bare the remarkable bed of a fall called Döda (dead) Fall, in which many "giant's caldrons" are exposed. In the uplands above the chain of lakes called Strömsvattudal, which are within the drainage area on the Ångerman, the Hälling stream forms the magnificent Hällingså Fall. In the southern mountain valleys of the region there are several beautiful falls, such as the Tännfors, not far from Åreskutan, the Storbo, Handöl and Rista.

Eastward from the main mountain range the highland region is divided into two belts: a middle belt of morainic deposits and marshes, and a coastal belt. The middle belt is gently undulating; viewed from rare eminences the landscape over the boundless forests resembles a dark green sea, through which the great rivers flow straight between steep, flat-topped banks, with long quiet reaches broken by occasional rapids. The few lakes they form in this belt are rather mere widenings in their courses; but the tributary streams drain numerous small lakes and peat-mosses. In the extreme north this belt is almost flat, a few low hills standing isolated and conspicuous; and the rivers have serpentine courses, while steep banks are absent. The middle belt merges into the coastal belt, covered by geologically recent marine deposits, reaching an extreme height of 700 to 800 ft., and extending inland some 60 to 80 m. in the north and 40 m. in the south. Small fertile plains are characteristic, and the rivers have cut deep into the soft deposits of sand and clay, leaving lofty and picturesque bluffs (*nipor*).

Central Lowlands. The orographical division of the central lowlands bears comparison in formation with the coastal belt of marine deposits to the north. Here are flat fertile plains of clay, well wooded, with innumerable lakes, including the four great lakes, Vener, Vetter, Mälar and Hjelmar. These, except the last, far exceed in area any of the northern lakes, and even Hjelmar (185 sq. m.) is only exceeded by Hornafvan-Storafvan. The areas of the other three lakes are respectively 2149, 733 and 449 sq. m. Vener, Vetter and Hjelmar are broad and open; Mälar is very irregular in form, and of great length. Mälar, Vener and Hjelmar contain many islands; in Vetter there are comparatively few. None of the lakes is of very great depth, the deepest sounding occurring in Vetter, 390 ft. In Hjelmar, which measures 38 m. from east to west, and is 12 m. in extreme width, the greatest depth is only 59 ft., but as its flat shores were formerly subject to inundation its level was sunk 6 ft. by deepening the navigable channel through it and clearing out various waterways (the Eskilstuna river, Hjelmar canal, &c.) in 1878–1887. The scenery of these lakes, though never grand, is always quietly beautiful, especially in the case of Mälar, the wooded shores and islands of which form a notable feature in the pleasant environs of the city of Stockholm. The elevation of the central lowlands seldom exceeds 300 ft., but a few isolated heights of Silurian rock appear, such as Kinnekulle, rising 988 ft. above sea-level on the south-eastern shore of Vener, Billingen (978 ft.) between that lake and Vetter, and Omberg (863 ft.) on the eastern shore of Vetter. Noteworthy local features in the landscape of the central lowlands are the eskers or gravel-ridges (*åsar*), traversing the land in a direction from N.N.W. to S.S.E., from 100 to 200 ft. in height above the surrounding surface. Typical instances occur in the cities of Stockholm (Brunkebergsåsen) and Upsala (Upsala-åsen).

Småland Highlands. South of the central lowlands the so-called Småland highlands extend over the old province of Småland in the south-east, and lie roughly south of Lake Vetter and of Gothenburg, where they reach the south-west coast. The general elevation of this region exceeds 300 ft., and in the eastern part 600 ft.; the principal heights are Tomtabacken (1237 ft.) and Ekbacken (1175 ft.), about 25 m. respectively south-east and west of the town of Jönköping at the southern extremity of Lake Vetter. Gentle forest-clad undulations, many small lakes and peat-mosses, are characteristic of the region; which, in fact, closely resembles the middle belt of the northern highland region. The Småland highlands abut southward upon the plains of Skåne, the last of the main orographical divisions, which coincides roughly with the old province of Skane (Scania). Level plains, with rich open meadows and cultivated lands, the monotony of which is in some parts relieved by beech woods, are separated by slight ridges with a general direction from N.W. to S.E., such as Hallandsåsen in the north-west, with an extreme elevation of 741 ft.

Rivers of the South. The hydrographical survey may now be completed. The Dal river, which enters the Gulf of Bothnia near Gefle, is formed of the union of eastern and western branches (Oster Dal, Vester Dal) not far from the town of Falun. The eastern branch drains various small lakes on the Norwegian frontier, and in its lower course passes through the beautiful Lake Siljan. The length of the whole river including the eastern as the main branch is 283 m. The Klar river (228 m.) rises as the Faemund river in Faemundsjö, a large lake in Norway close west of the sources of the Dal. The Klar flows south into Lake Vener, which is drained to the Cattegat by the short Göta river, on which, not far below the lake, are the celebrated falls of Trollhättan. Lake Vetter drains eastward by the Motala to the Baltic, Lake Mälar drains in the same direction by a short channel at Stockholm, the normal fall of which is so slight that the stream is sometimes reversed. The Småland highlands are drained to the Baltic and Cattegat by numerous rivers of less importance. Excepting Finland no country is so full of lakes as Sweden. About 14,000 sq. m., nearly one-twelfth of the total area, are under water.

Coast. The coast of Sweden is not indented with so many or so deep fjords as that of Norway, nor do the shores of the Gulf of Bothnia, the Baltic and the Cattegat share in the peculiar grandeur of the North Sea coast. All, however, have a common feature in the fringe of islands which, throughout nearly the entire length, shelters the coast of the mainland from the open sea. This "skerry-fence" (in Swedish, *skärgård*) is only interrupted for any considerable distance (in the case of Sweden) round the southern shore off the flat coast of Skåne, between the towns of Varberg on the west and Åhus on the east. Between it and the mainland lies a connected series of navigable sounds of the greatest advantage to coastwise traffic, and also of no little importance as a natural defence. The skärgård of the Cattegat, north of Varberg, is bald and rugged. The two largest islands are Orust and Tjörn, north of Gothenburg. Off the south-east coast the place of the skärgård is in a measure taken by the long narrow island of Öland, but north of this the skärgård begins to widen, and the most considerable fjords are found, such as Bråvik, which penetrates the land for 35 m. nearly up to the town of Norrköping. The island belt is widest (some 45 m.) off the city of Stockholm, the approach to which from the sea is famous for its beauty. Farther north, a narrow sound (Ålands Haf) intervening on the Swedish side, the vast Åland archipelago, belonging to Russia, extends across to the Finnish coast. The skärgård of the Gulf of Bothnia is less fully developed than that of either the Baltic or the Cattegat. The islands of the skärgård as a whole are rugged and picturesque, though never lofty like many of those off the Norwegian coast. In the Baltic many are well wooded, but the majority are bare or heath-clad, as are those of the Gulf of Bothnia. Of the large islands in the Baltic and Cattegat, besides Öland, only Gotland is Swedish.

Geology.—The fundamental rocks of Sweden belong to the Azoic or pre-Cambrian formation, and consist of crystalline rocks. Three divisions are distinguished by some authors—the grey gneiss, the red iron gneiss and the granulite.

The grey gneiss predominates in the northern and eastern parts of the country, from Vesternorrland down to the province of Kalmar. The rock has a prevalent grey colour, and contains as characteristic minerals garnet and in some parts graphite.

The red iron gneiss prevails in western Sweden in the provinces of Vermland, Skaraborg, Elfsborg, and down to the province of Kristianstad. The formation is very uniform in its character, the gneiss having a red colour and containing small granules of magnetite, but, nevertheless, not a single iron mine belongs to this region. The red gneiss contains in many places beds or masses of hyperite.

The granulite, also called eurite and hälleflinta, is the most important of the Pre-Cambrian formation, as it contains all the metalliferous deposits of Sweden. It prevails in the middle part of the country, in Kopparberg, Vestmanland, Upsala and parts of Vermland. It occurs also in Östergötland, Kalmar and Kronoberg. The rock is a very compact and fine-grained mixture of felspar, quartz and mica, often graduating to mica schist, quartzite and gneiss. With these are often associated limestones, dolomites and marbles containing serpentine (Kolmården). The metalliferous deposits have generally the form of beds or layers between the strata of granulite and limestone. They are often highly contorted and dislocated.

The iron deposits occur in more or less fine-grained gneiss or granulite (Gellivara, Grängesberg, Norberg, Striberg), or separated from the granulite by masses of augitic and amphibolous minerals (*grönskarn*), as in Persberg and Nordmark. Sometimes they are surrounded by hälleflinta and limestone, as at Dannemora, Långban, Pajsberg, and then carry manganiferous minerals. Argentiferous galena occurs at Sala in limestone, surrounded by granulite, and at Guldsmedshytta (province of Örebro) in dark hälleflinta. Copper pyrites occur at Falun in mica-schists, surrounded by hälleflinta. Zinc-blende occurs in large masses at Ammeberg, near the northern end of Lake Vetter. The cobalt ore consists of cobalt-glance (Tunaberg in the province of Södermanland) and of linneite (at Gladhammar, near Vestervik). The nickel ore of Sweden is magnetic pyrites, containing only a very small percentage of nickel, and generally occurs in diorite and greenstones. Besides the crystalline gneiss and hälleflinta there are also sedimentary deposits which are believed to be of pre-Cambrian age. The most important of these are the Dala Sandstone (chiefly developed in Dalarne), the Almasåkra and Visingsö series (around Lake Vetter) and the Dalsland formation (near Lake Vener).

Large masses of granite are found in many parts of Sweden, in Kronoberg, Örebro, Göteborg, Stockholm, &c. Sometimes the granite graduates into gneiss; sometimes (as north of Stockholm) it encloses large angular pieces of gneiss. Intrusions of hyperite, gabbro (anorthite-gabbro at Rädmansö in the province of Stockholm) and diorite are also abundant.

The Cambrian formation generally occurs along with the Ordovician, and consists of many divisions. The oldest is a sandstone, in which are found traces of worms, impressions of *Medusae*, and shells of *Mickwitzia*. The upper divisions consist of bituminous limestones, clay-slates, alum-slate, and contain numerous species of trilobites of the genera *Paradoxides*, *Conocoryphe*, *Agnostus*, *Sphaerophthalmus*, *Peltura*, &c. The Ordovician formation occurs in two distinct facies—the one shaley and containing graptolites; the other calcareous, with brachiopods, trilobites, &c. The most constant of the calcareous divisions is the Orthoceras limestone, a red or grey limestone with *Megalaspis* and *Orthoceras*. The subdivisions of the system may be grouped as follows: (1) Ceratopyge Limestone; (2) Lower Graptolite Shales and Orthoceras Limestone; (3) Middle Graptolite Shales, Chasmops and other Limestones, Trinucleus beds. The Cambrian and Ordovician strata occur in isolated patches in Vesterbotten, Jemtland (around Storsjö), Skaraborg, Elfsborg, Örebro, Östergötland and Kristianstad. The whole of the island of Öland consists of these strata. The deposits are in most places very little disturbed and form horizontal or slightly inclined layers. South of Lake Vener they are capped by thick beds of eruptive diabase (called *trapp*). North of Lake Siljan (province of Kopparberg), however, they have been very much dislocated. The Silurian has in Sweden almost the same character as the Wenlock and Ludlow formation of England and consists partly of graptolite shales, partly of limestones and sandstones. The island of Gotland consists entirely of this formation, which occurs also in some parts of the province of Kristianstad. In the western and northern alpine part of Sweden, near the boundaries of Norway, the Silurian strata are covered by crystalline rocks, mica schists, quartzites, &c., of an enormous thickness, which have been brought into their present positions upon a thrust-plane. These rocks form the mass of the high mountain of Åreskutan, &c.

The Triassic formation (Rhaetic division) occurs in the northern part of Malmöhus. It consists partly of sandstones with impressions of plants (cycads, ferns, &c.), and partly of clay-beds with coal.

The Cretaceous formation occurs in the provinces of Malmöhus and Kristianstad and a few small patches are found in the province of Blekinge. Only the higher divisions (Senonian and Danian) of the system are represented. The deposits are marls, sandstones and limestones, and were evidently formed near the shore-line.

The most recent deposits of Sweden date from the Glacial and Post-Glacial periods. At the beginning of the Glacial period the height of Scandinavia above the level of the sea was greater than at present, Sweden being then connected with Denmark and Germany and also across the middle of the Baltic with Russia. On the west the North Sea and Cattegat were also dry land. On the elevated parts of this large continent glaciers were formed, which, proceeding downwards to the lower levels, gave origin to large streams and rivers, the abundant deposits of which formed the diluvial sand and the diluvial clay. In most parts of Sweden these deposits were swept away when the ice advanced, but in Skåne they often form still, as in northern Germany, very thick beds. At its maximum the inland ice not only covered Scandinavia but also passed over the present boundaries of Russia and Germany. When the climate became less severe the ice slowly receded, leaving its moraines, called in Sweden *krosstenslera* and *krosstensgrus*. Swedish geologists distinguish between *bottengrus* (bottom gravel, bottom moraine) and ordinary *krossgrus* (terminal and side moraine). The former generally consists of a hard and compact mass of rounded, scratched and sometimes polished stones firmly embedded in a powder of crushed rock. The latter is less compact and contains angular boulders, often of a considerable size, but no powder. Of later origin than the krosstensgrus is the *rullstensgrus* (gravel of rolled stones), which often forms narrow ranges of hills, many miles in length, called *åsar*. During the disappearance of the great inland ice large masses of mud and sand were carried by the rivers and deposited in the sea. These deposits, known as glacial sand and glacial clay, cover most parts of Sweden south of the provinces of Kopparberg and Vermland, the more elevated portions of the provinces of Elfsborg and Kronoberg excepted. In the glacial clay shells of *Yoldia arctica* have been met with in many places (*e.g.* near Stockholm). At this epoch the North Sea and the Baltic were connected along the line of Vener, Vetter, Hjelmar and Mälar. On the other side the White Sea was connected by Lakes Onega and Ladoga with the Gulf of Finland and the Baltic. In the depths of the Baltic and of Lakes Vener and Vetter there actually exist animals which belong to the arctic fauna and are remnants of the ancient ice-sea. The glacial clay consists generally of alternate darker and lighter coloured layers, which give it a striped appearance, for which reason it has often been called *hvarfvig lera* (striped clay). The glacial clay of the Silurian regions is generally rich in lime and is thus a marl of great fertility. The deposits of glacial sand and clay are found in the southern part of Sweden at a height ranging from 70 to 150 ft. above the level of the sea, but in the interior of the country at a height of 400 ft. above the sea.

On the coasts of the ancient ice-sea, in which the glacial clay was deposited, there were heaped-up masses of shells which belong to species still extant around Spitzbergen and Greenland. Most renowned among these shell-deposits are the Kapellbackarne near Uddevalla. With the melting of the great ice-sheet the climate became milder, and the southern part of Sweden was covered with shrubs and plants now found only in the northern and alpine parts of the country (*Salix polaris*, *Dryas octopetala*, *Betula nana*, &c.). The sea fauna also gradually changed, the arctic species migrating northward and being succeeded by the species existing on the coasts of Sweden. The Post-Glacial period now began. Sands (*mosand*) and clays (*åkerlera* and *fucuslera*) continued to be deposited on the lower parts of the country. They are generally of insignificant thickness. In the shallow lakes and enclosed bays of the sea there began to be formed and still is in course of formation a deposit known by the name *gyttja*, characterized by the diatomaceous shells it contains. Sometimes the gyttja consists mainly of diatoms, and is then called *bergmjöl*. The gyttja of the lakes is generally covered over by peat of a later date. In many of the lakes of Sweden there is still in progress the formation of an iron ore, called *sjömalm*, ferric hydroxide, deposited in forms resembling peas, coins, &c., and used for the manufacture of iron. (P. LA.)

Climate.—The climate of the Scandinavian peninsula as a whole is so far tempered by the warm Atlantic drift from the south-west as to be unique in comparison with other countries of so high a latitude. The mountains of the Keel are not so high as wholly to destroy this effect over Sweden, and the maritime influence of the Baltic system has also to be considered. Sweden thus occupies a climatic position between the purely coastal conditions of Norway and the purely continental conditions of Russia; and in some years the climate inclines to the one character, in others to the other. As a result of the wide latitudinal extent of the country there are also marked local variations to be contrasted. About one-seventh of the whole country is north of the Arctic Circle. The mean annual temperature ranges from 26·6° F. at Karesuando on the northern frontier to 44·8° at Gothenburg and 44·6° at Lund in the south (or 29·5° to 45° reduced to sea-level). Between these extremes the following actual average temperatures have been observed at certain stations from north to south which are appropriately grouped for the purpose of comparison (heights above sea-level following each name):—

Jockmock (850 ft.), at the foot of the lake-chain on the Little Lule River—29·7°; and Haparanda (30 ft.), at the head of the Gulf of Bothnia—32·4°.

Stensele (1076 ft.), at the foot of the lake-chain on the Ume—31·8°; and Umeå (39 ft.) at its mouth on the Gulf of Bothnia—34·9°.

Östersund (1056 ft.) on Storsjö—35·2°; and Hernösand (49 ft.) on the Gulf of Bothnia—37·8°.

Karlstad (180 ft.) at the head of Lake Vener—42·3°; Örebro (102 ft.) at the west of Lake Hjelmar—41·4°; and Stockholm (144 ft.)—42·1°.

Gothenburg (26 ft.) on the Cattegat—44·8°; Jönköping (312 ft.)

at the south of lake Vetter—42·4°; and Vestervik (43 ft.) on the Baltic—43·2°.

But the local variations thus indicated are brought out more fully by a consideration of seasonal, and especially winter, temperatures. In Sweden July is generally the hottest month, the average temperature ranging from about 51° to 62°. In January, however, it ranges from 4° to 32° (February is generally a little colder). Moreover, there are two well-marked centres of very low winter temperature in the inland parts. The one is in the mountainous region of the south of Jemtland and the north of Dalarne, extending into Norway and thus lying in the middle of the peninsula about 62° N. Here the average temperature in January is 8·5°, whereas at Östersund it is over 15°. The other and more strongly marked centre is in the far north, extending into Norway and Finland, where the average is 3·8°. The effect of the spinal mountain range in modifying oceanic conditions is thus illustrated. The same effect is well shown by the linguiform isotherms. In January, for example, the isotherm of 14°, after skirting the north coast of the Scandinavian peninsula, turns southward along the Keel, crossing the upper part of the district of the great northern lakes. It continues in this direction as far as the northern end of Lake Mjösen in Norway (61° N.), then turns sharply north-north-eastward, runs west of Lake Siljan and bends north-east to strike the Bothnian coast near Skellefteå. In July, on the other hand, the isotherms show an almost constant temperature all over the country, and the linguiform curves are wanting.

The relative length of the seasons shows contrasts similar to those of temperature. In the north spring begins in May, summer in the middle of June and autumn in the middle of August. In the south and south-west spring begins in March, summer in the middle of May and autumn in October. At Karesuando the last frost of spring occurs on an average on the 15th of June, and the first of autumn on the 27th of August, though night frosts may occur earlier; while at Stockholm 4½ months are free of frost. Ice forms about October in the north, in November or December in the midlands and south, and breaks up in May or June and in April respectively. Ice covers the lakes for 100 to 115 days annually in the south, 150 in the midlands and 200 to 220 in the north. A local increase of the ice period naturally takes place in the upper parts of the Småland highlands; and in the case of the great lakes of Norrland, the western have a rather shorter ice period than the eastern. As to the seas, the formation of ice on the west and south coasts is rare, but in the central and northern parts of the Baltic drift-ice and a fringe of solid ice along the coast arrests navigation from the end of December to the beginning of April. Navigation in the southern part of the Gulf of Bothnia is impeded from the end of November to the beginning of May, and in the north the gulf is covered with ice from November to the last half of May. Snow lies 47 days on an average on the plains of Skåne, while in the north it lies from 140 to 190 days.

The northern summers find compensation for brevity in duration of sunshine and light. At Karesuando in 68° 26′ N. and 1093 ft. above sea-level the sun is seen continuously above the horizon from the 26th of May to the 18th of July; at Haparanda for 23 hours, at Stockholm for 18½ hours and at Lund for 17½ hours at the summer solstice. Atmospheric refraction causes the sun to be visible for periods varying from south to north for a quarter to half an hour after it has actually sunk below the horizon. With the long twilight, perhaps the most exquisite period of a season which provides a succession of beautiful atmospheric effects, daylight lasts without interruption from the 16th to the 27th of June as far south as Hernösand (62° 38′ N.).

The average annual rainfall for Sweden is 19·72 in., locally increasing on the whole from north to south, and reaching a maximum towards the south-west, precipitation on this coast greatly exceeding that on the south-east. Thus the average in the north of Norrland is 16·53 in., in the south of Norrland 22·6 in. At Borås, midway between the south end of Lake Vetter and the Cattegat, the average is 35·08 in., and 45·82 in. were registered in 1898. At Kalmar, however, on the Baltic opposite Öland, the average is 14·6 in. This is an extreme instance for the locality, but the minimum for all Sweden is found at Karesuando, with 12·32 in. The period of maximum is generally the latter half of summer, and the minimum in February and March; but the maximum occurs in October at coast stations in Skåne and in the island of Gotland. The proportion of total precipitation which falls as snow ranges from 36% in the north to 9% in the south.

Flora.—In the preceding physical description indications are given of the vast extent of forest in Sweden. The alpine treeless region occupies only the upper flanks of the spinal mountain-range above an elevation varying from 1800 ft. in the north to 3000 ft. in the south. It is belted by a zone of birch woods, with occasional mountain-ash and aspen, varying in width from about 20 m. in the north to a fraction of a mile in the south. Below this extends a great region of firwood covering the whole country north-east of Lake Vener and north of the Dal River. The fir (*Pinus sylvestris*) and pine (*Pinus abies*) are the predominating trees Spruce is common, and even predominates in the higher parts (between the great valleys and immediately below the birch-belt) in the north of Norrland. South of the southern limit indicated, in the midland district of the great lakes, the oak (*Quercus pedunculata*) appears as well as pine and fir; and, as much of this area is under cultivation, many other trees have been introduced, as the ash, maple, elm and lime. South of a line running, roughly, from the foot of Lake Vener to Kalmar on the Baltic coast the beech begins to appear, and in Skåne and the southern part of the Cattegat seaboard becomes predominant in the woods which break the wide cultivated places. Of wild flowering plants only a very few are endemic species (though more are endemic varieties); the bulk are immigrants after the last glacial epoch. Of these most are common to arctic lands, or occur as alpine plants in lower latitudes. The number of species decreases according to geographical distribution from south to north; thus while upwards of 1000 are found in Skåne, there are only about 700 in the midlands, 500 in the lower parts of southern Norrland and less than 200 in the extreme north.

Fauna.—The effects of the great latitudinal range of Sweden on its climate and flora has its parallel to a modified extent in the case of fauna. Only a few animals are common to the entire country, such as the hare (*Lepus timidus*) and the weasel; although certain others may be added if the high mountain region be left out of consideration, such as the squirrel, fox and various shrews. Among large animals, the common bear and the wolf have been greatly reduced in numbers even within later historic times. These and the lynx are now restricted to the solitary depths of the northern forests. Characteristic of the high mountainous region are the arctic fox, the glutton and the lemming, whose singular intermittent migrations to the lowlands have a considerable temporary influence on the distribution of beasts and birds of prey. There may also be mentioned the wild reindeer, which is rare, though large domesticated herds are kept by the Lapps. The elk, carefully preserved, haunts the lonely forests from the Arctic Circle even to the Småland highlands. The roe-deer and red-deer are confined to the southern parts; though the first is found in the south of the midland plains. In these plains the fox is most abundant, and the badger and hedgehog are found. Martens and otters are to some extent hunted for their skins. A white winter fur is characteristic of several of the smaller animals, such as the hare, fox and weasel. The common and grey seals are met with in the neighbouring seas, and *Phoca foetida* is confined to the Baltic. Among birds by far the greater proportion is migrant. Characteristic types common to the whole country are the teal, snipe, golden plover and wagtail. In the northern mountains the ptarmigan is common, and like other creatures assumes a white winter dress; ducks and other water-fowl frequent the lakes; the golden eagle, certain buzzards and owls are found, and among smaller birds the Lappland bunting (*Plectrophanes laponicus*) may be mentioned. In the coniferous forests the black grouse, hazel grouse and willow grouse, capercailzie and woodcock are the principal game birds; the crane is found in marshy clearings, birds of prey are numerous, and the Siberian jay in the north and the common jay in the south are often heard. But in the northern forests small birds are few, and even in summer these wilds give a strong general impression of lifelessness. In the midlands the partridge is fairly common, though not readily enduring the harder winters; and ring-doves and stock-doves occur. The lakes are the homes of a variety of aquatic birds. On the coasts a number of gulls and terns are found, also the eider-duck and the sea-eagle, which, however, is also distributed far over the land. The species of reptiles and amphibians are few and chiefly confined to the southern parts. There are three species of snake, including the viper; three of lizard; and eleven of batrachians. The rivers and lakes are generally well stocked with fish, such as salmon, trout of various species, gwyniad and vendace (especially in the north), pike, eels, perch of various species, turbot, bream and roach. The few sportsmen who have visited the higher parts of the great northern rivers have found excellent trout-fishing, with pike, perch, char and grayling, the char occurring in the uppermost parts of the rivers, and the grayling below them. The fisheries, both fresh-water and sea, are important, and fall for consideration as an industry. The herring, cod, flatfish, mackerel and sprat are taken in the seas, and also great numbers of a small herring called *strömming.* In the brackish waters of the east coast sea fish are found, together with pike, perch and other fresh-water forms. The crayfish is common in many places in central and southern Sweden. Pearls are sometimes found in the fresh-water mussel (*Margaritana margaritifera*); thus a tributary of the Lilla Lule River takes its name, Perle River, from the pearls found in it. Among the lower marine animals a few types of arctic origin are found, not only in the Baltic but even in Lakes Vener and Vetter, having remained, and in the case of the lakes survived the change to fresh water, after the disappearance of the connexion with the Arctic seas across the region of the great lakes, the Baltic, and north-east thereof. The molluscan fauna is fairly rich, and insect fauna much more so, even in the north. In summer in the uplands and the north the mosquito is sufficiently common to cause some little annoyance.

People.—The population of Sweden in 1900 was 5,136,441. The census is taken in an unusual manner, being drawn up from the registries of the clergy according to parishes every ten years. Approximate returns are made by the clergy annually. The following table shows the distribution of population in that year through the *län* or administrative districts. The first column shows the older divisions of the county into provinces, the names and boundaries of which differ in many cases from the *län*. These names, as appears elsewhere in this article, remain in common use. The distribution of provinces and *län* between the three main territorial divisions, Norrland (northern), Svealand (central) and Götaland (southern) is also indicated.

Old Provinces.	Län.	Area sq. m.	Pop. 1900.

The population in 1908 was about 5,429,600. In 1751 it was 1,802,373, and in 1865, 4,114,141. The average annual increase was 7·86 per thousand in the 19th century, reaching a maximum of 10·39 in 1841–1860, before the period of extensive emigration set in. Emigrants numbered 584,259 men and 424,566 women between 1851 and 1900, these figures helping to account for the considerable excess of women over men in the resident population, which in 1900 was as 1049 to 1000. The periods of greatest emigration were 1868–1873 and 1879–1893; the decline in later years is regarded as a favourable sign. The United States of America receive a large majority of the emigrants, and only a very small percentage returns. The Swedish people belong to the Scandinavian branch, but the population includes in the north about 20,000 Finns and 7000 Lapps. Other foreigners, however, are few, and the population is as a whole homogeneous. Immigrants in the period 1851–1900 numbered only 165,357.

Population is naturally denser in the south than in the north, and densest of all in the districts along the southern coasts; thus Malmöhus Län has about 220 persons per sq. m., Göteborg och Bohus Län 174 and Blekinge 127. In Norrland as a whole, however, there are less than 9 persons per sq. m., in Norrbottens Län less than 4, and in the uplands of this division and Vesterbottens Län much less than this. However, the annual increase per thousand has been greater in Norrland than elsewhere. The annual excess of births over deaths is high, the proportion being as 1·68 to 1. The birth-rate between 1876 and 1900 averaged 28·51 per thousand; the death-rate between 1891 and 1900 was 16·36 per thousand, the lowest ever recorded over such a period for any European country. The lowest mortality is found in the districts about Lakes Vener and Vetter; the highest in Norbotten, the east midland districts, Skåne, and Göteborg och Bohus Län.

The percentage of illegitimacy is rather high (though it decreased during the second half of the nineteenth century); one cause of this may be found in the fact that the percentage of married persons is lower than in most European countries. As regards social evils generally, however, the low, though undoubtedly improving, standard of Sweden has had one of its chief reasons in the national intemperance. In 1775 Gustavus III. made the sale of spirits (*brännvin*) a government monopoly, and the drinking habit was actually fostered. About 1830 this evil reached its highest development, and it is estimated that nine gallons of spirits were then consumed annually per head of the population. Mainly through the efforts of Peter Wieselgren, dean of Gothenburg (1800–1877), a strong temperance reform movement set in, and in 1855 important liquor laws were passed to restrict both production and sale of intoxicating liquors. The so-called Gothenburg System, providing for municipal control of the sale of intoxicants (see LIQUOR LAWS), came into full operation in Gothenburg in 1865. The temperance movement has had its reward; the average of consumption of beer and spirits in Sweden is considerably lower than in Europe as a whole, though the effect of intoxicants is sometimes very apparent.

A marked difference of temperament is noticeable between the Swedes and Norwegians, the Swedes being the more light-hearted and vivacious. In some of the more remote parts of the country old customs are maintained and picturesque local costumes still worn, as in Dalecarlia (*q.v.*). The Lapps moreover retain their distinctive dress. In other cases early costumes are preserved only as a historical reminiscence at festivities. Although the characteristic celebrations at weddings or periodical festivals are, as elsewhere, decreasing in favour, there are certain occasions which are observed as holidays with much ceremony. Such are Christmas Day, and, not unnaturally in this northern land, Midsummer (June 23 and 24). The food of the people in the midlands and south is plentiful and good; in the remoter parts of the north an unfavourable summer is followed by a winter of scarcity or even famine; and in these parts meat is little used. Rye is extensively employed in the rural districts for the making of a hard bread in flat cakes (*knäckebröd*). A prevalent custom among the better classes is that of beginning meals with a selection of such viands as anchovies, smoked salmon or slices of meat, of which a number of small dishes are provided (*smörgåsbord*). These are taken with bread and butter and a glass of spirits. The more characteristic Swedish sports are naturally those of the winter. These include ski-running (*skidlöpning*), skating and skate-sailing, tobogganing and sledging. The numerous inland waters and sheltered channels within the *skärgård* have caused the high development of sailing as a summer sport, the Royal Swedish Yacht Club having its headquarters in Stockholm. Athletic sports are in high favour, especially such winter sports as snow-shoeing (*ski*), and, among ball games, lawn-tennis, and to some extent football, together with the game of *pärk*, peculiar to Gotland, are played.

Towns.—In the first half of the 19th century the percentage of urban population remained nearly stationary at a little less than 10. In 1880 it was 15·12, and in 1900 21·49. The towns with a population exceeding 15,000 in 1900 are Stockholm (300,624), Gothenburg (130,609), Malmö (60,857), Norrköping (41,008), Gefle (29,522), Helsingborg (24,670), Karlskrona (23,955), Jönköping (23,143), Upsala (22,855), Örebro (22,013), Lund (16,621), Borås (15,837), Halmstad (15,362).

Architecture.

Swedish towns, though rarely of quite modern foundation, generally appear so, for the use of brick in building is mainly of modern introduction, and is still by no means general, so that the partial or total destruction of a town by fire is now only less common than formerly. The rectangular method of laying out streets is general, and legislation has been directed against narrow streets and buildings of excessive height. The common material of the characteristic domestic architecture in rural districts is wood, except in Skåne, where stone is available and has been used from early times. Some of the old wooden farm-buildings, especially in Dalarne, such as are preserved in Skansen Museum at Stockholm, are extremely picturesque. Another notable form in old wooden building is the belfry (*klokstapel*) of some village churches, examples of which are seen at Habo near Jönköping and Håsjö in Jemtland on the northern railway. In the midlands and south fine castles and manor houses of the 16th and 17th centuries are fairly numerous, and there are a few remains of previous date. The fortified dwelling-house at Glimmingehus in the extreme south near Simrishamn is a good early example. Several of the southern ports have old citadels. That of Kalmar, on its island, is specially fine, while those at Vestervik (Ståkeholm), Malmö, Falkenberg and Varberg may also be mentioned. Among country palaces or mansions that of Gripsholm is notable, overlooking Lake Mälar, the shores of which are specially

[1] The island and adjacent islets.
[2] Island included in Kalmar Län.
[3] Including the four great lakes, Vener, Vetter, Mälar Hjelmar, 3516 sq. m.

rich in historic sites and remains In ecclesiastical architecture Sweden possesses the noble cathedrals of Lund, Upsala and Linköping; while that of Skara, near the southern shore of Lake Vener, dates originally from 1150, and that of Strengnäs on Lake Mälar was consecrated in 1291. There is a remarkably perfect Romanesque church, with aisles, eastern apse and ambulatory, at Varnhem in Skaraborg Län, and there are a few village churches of the same period in this district and in Skåne. The monastic church at Vadstena on Lake Vetter is a beautiful example of Gothic of the 14th and 15th centuries. But the richest locality as regards ancient ecclesiastical architecture is the island of Gotland (*q.v.*).

Travel and Communications.—As a resort for foreign travellers and tourists Sweden lacks the remarkable popularity of Norway. The Göta canal route, however, is used by many; the uplands of Dalecarlia (Dalarne) are frequented; and the railway through the Jemtland highlands to Trondhjem gives access to a beautiful region, where numerous sanatoria are in favour with the Swedes themselves. The northern railway offers a land route to the Arctic coast of Norway. Along the southern coasts there are many watering-places. Marstrand near Gothenburg is one of the most fashionable; Strömstad, Lysekil and Varberg on the same coast, Ronneby on the Baltic, with its chalybeate springs, Visby the capital of Gotland, and several villages in the neighbourhood of Stockholm may also be noted. The headquarters of the Swedish Touring Club (*Svenska Turistföreningen*) are in Stockholm, but its organization extends throughout the country, and is of special value to travellers in the far north.

Railways.

The first railway in Sweden was opened for traffic in 1856, and the system has developed extensively; more so, in fact, in proportion to population, than in any other European country. About 8000 m. of railway are open, but extensions are constantly in progress. About two-thirds are private lines and one-third government lines. The central administration of the government lines is in the hands of a board of railway directors, and there are local administrative bodies for each of five districts. A railway council, created in 1902, acts as an advisory body on large economical questions and the like. Private railways are controlled by the regulations of the board, while a joint traffic union has as its object the provision of uniformity of administration, tariff, &c. The government has made grants towards the construction of some of the private lines, and has in a few cases taken over such lines. The railways form a network over the country as far north as Gefle and the district about Lake Siljan. The government works the trunk lines from Stockholm to Malmö, to Gothenburg and to Christiania as far as the Norwegian frontier, and other important through routes in the south. The great northern line is also worked by the government. It runs north from Stockholm roughly parallel with the east coast, throwing off branches to the chief seaports, and also a branch from Bräcke to Östersund and Storlien, where it joins a line from Trondhjem in Norway. At Boden the main line joins a line originally built to connect the iron-mines of Gellivara with the port of Luleå; the system is continued past Gellivara to Narvik on the Ofoten Fjord in Norway, this being far north of the Arctic Circle, and the line the most northerly in the world. The gauge of all the government lines and about 66% of the private lines is 1·435 metres (4 ft. 8½ in.). Nearly all the lines are single. Passenger travelling is slow, but extremely comfortable. The principal connexions with the south are made across the sound from Malmö to Copenhagen, and from Trelleborg to Sassnitz in Germany.

Inland Navigation.

The extensive system of natural waterways, especially in central Sweden, has been utilized to the full in the development of internal navigation, just as the calm waters within the skärgård afford opportunity for safe and economical coastwise traffic. The earliest construction of canals dates from the 15th century, the patriot Engelbrekt and King Gustavus Vasa both foreseeing its importance. The theories of construction remained rudimentary until early in the 19th century, when the Göta (*q.v.*) canal was opened. The total length of the canalized water-system of Sweden is a little over 700 m., though wholly artificial waterways amount only to 115 m. out of this total. A large local traffic is carried on by steam launches on the lakes during the season of open navigation; and vessels have even been introduced on some of the lakes and rivers of the far north, principally in connexion with the timber trade. Posting, which is of importance only in the highland districts and the valley roads of Norrland, is carried on by posting-stations (*skjutsstation*) under government regulations; similar regulations apply when, as in the upper valleys of the great northern rivers, rowing boats on the lakes form the only means of travel. The condition of the high roads is fair as a whole, and has been much improved by increased state grants towards their upkeep; but in Norrland they are naturally not of the best class. The postal and telegraph system is efficacious, and the telephone service, maintained partly by the state and partly by companies, is very fully developed. About twenty telephones are in use per thousand of population, and a system of trunk-lines between the important towns has been established since 1889.

Agriculture.—Of the total land area of Sweden only about 12% is arable or meadow land, but the percentage varies greatly in different parts, as will be understood from a recollection of the main physical divisions. Thus in Skane nearly 60% of the land is under cultivation; in the midlands about 30%; in the north from 4·5% in southern Norrland to 3% in northern Norrland. Almost exactly half the total area is under forest, its proportion ranging from 25% in Skåne to upwards of 70% in the inland parts of Svealand and in the south of Norrland. Land which is neither cultivable nor under forest (marsh land or, in the northern mountainous districts, land above the upper limit of the forests) amounts to 61% in the far north and 36% in the Småland highlands, but only to 15% in the central plains and in Skåne. In the more highly cultivated districts of the south reclamation of such lands is constantly proceeding. Agriculture and cattle-breeding employ over one-half the whole population. The average size of farms is 25 acres of cultivated land; only 1% exceeds 250 acres, whereas 23% are of 5 acres or less. The greater part of the land has always been held by small independent farmers (only about 15% of the farms are worked by tenants), but until late in the 18th century a curious method of parcelling the land resulted in each man's property consisting of a number of detached plots or strips, the divisions often becoming so minute that dissension was inevitable. Early in the 19th century various enactments made it possible for each property to become a coherent whole. A legal parcelling (*laga skifte*) was introduced in 1827 and slowly carried out in the face of considerable local opposition; indeed, in the island of Gotland the system could not be enforced until 1870–1880. Roughly about 48·5% of the total cultivated area is under cereals, 33·8 under fodder plants, 5·8 under root-crops, and 11·8 fallow, this last showing a steady decrease. Oats, rye, barley, mixed grain and wheat are the grain-crops in order of importance. During the 19th century the percentage under wheat showed a general tendency to increase; that under oats increased much in the later decades as livestock farming became common, rye maintained a steady proportion, but barley, formerly the principal grain-crop, decreased greatly. This last is the staple crop in Norrland, becoming the only grain-crop in the extreme north; in the richer agricultural lands of the midlands and south rye is predominant in the east, oats in the west. The high agricultural development of the plains of Skåne appears from the fact that although that province occupies only one-fortieth of the total area of Sweden, it produces 30% of the entire wheat crop, 33% of the barley, 18% of the rye and 13% of the oats. A system of rotation (cereal, roots, grass) is commonly followed, each division of land lying fallow one year as a rule; not more than two ripe grain-crops are commonly taken consecutively. Potatoes occupy 4·4% of the total area, and other root-crops 1·4%. These include the sugar-beet, the profitable growing of which is confined to Skåne and the islands of Öland and Gotland. The sugar industry, however, is very important. Orchards and gardens occupy about 1% of the cultivated area. Fruit-trees are grown, mainly in the south and midlands; northward (as far as Hernösand) they flourish only in sheltered spots on the coast. Between 1850 and 1900 the total head of livestock increased from 4,500,000 to 5,263,000, and the great advance of cattle-farming is evident from the following proportions. Whereas in 1870–1875 imported cattle and cattle-farming produce exceeded exports as 12 to 7, in 1900 the value of exports was nearly double that of imports; and it may be added that whereas as late as 1870–1880 the exports of agricultural produce exceeded imports in value, in 1896–1900 they were less than one-tenth. The principal breeds of cattle are the alpine in Norrland, and Ayrshire, short-horn, and red-and-white Swedish in the midlands and south. The Gotland, an old native light yellow breed, survives in the island of Gotland. Oxen, formerly the principal draught animals, have been replaced by horses. Cattle, especially cows, and pigs form the bulk of the livestock, but sheep and goats have greatly decreased in numbers. The Lapps own upwards of 230,000 head of reindeer. Dairy-farming is profitable, England and Denmark being the principal foreign consumers of produce, and the industry is carefully fostered by the government. A board of agriculture had been in operation for many years when in 1900 a separate department of agriculture was formed. There are one or more agricultural societies in each län, and there are various state educational establishments in agriculture, such as the agricultural high schools at Ultuna near Upsala, and at Alnarp near Lund in Skåne, an important agricultural centre, with dairy schools and other branch establishments. Finally, there are numerous horticultural societies, large nurseries and gardening schools at Stockholm, Alnarp and elsewhere, and botanical gardens attached to the universities of Lund and Upsala.

Forests and Forestry.—Of the forests about one-third are public; the majority of these belong to the Crown, while a small proportion belongs to hundreds and parishes. The remainder is in private hands. The public forests are administered by the office of Crown lands through a forest service, which employs a large staff of forest-masters and rangers. The private forests are protected from abuse chiefly by the important legislation of 1903, which prescribes penalties for excessive lumbering and any action liable to endanger the regrowth of wood. The administration of the law devolves upon local forest conservancy boards. In the great fir forests of the north the limit set in respect of cutting down living trees for sawing and export is a diameter of the trunk, without bark, of 8¼ in. at 15½ ft. from the base. Members of the forest service undergo a preliminary course of instruction at a school of forestry, and a further course at the Institute of Forestry, Stockholm, which dates from 1828. There are very numerous sawmills, using water-power, steam and electricity; they are situated chiefly in the coast districts of the Gulf of Bothnia, from Gefle northwards, especially in the neighbourhood of Sundsvall and along the Angerman River, and in the neighbourhood of all the ports as far north as Luleå and Haparanda. There are also upland mills in Dalarne and Vermland, and a considerable number in the neighbourhood of Gothenburg. The wood-pulp industry centres in the districts west and north of Lake Vener and south of Lake Vetter. In the north vast quantities of timber are floated down the great rivers, and the lesser streams are used as floating-ways by the provision of flumes and dams. The millowners either own forests, or lease the right of cutting, or buy the timber when cut, in the Crown or private forests. Among the special articles exported may be mentioned railway-sleepers, pit-props, and wood-pulp.

Fisheries.—The sea-fisheries, which are prosecuted principally in the calm waters within the skärgård, are a variable source of wealth. For example, in 1894 nearly 2,000,000 cwt. of fresh fish (principally herring) were exported, but in subsequent years the fisheries were much less prolific; in 1900 only 80,000 cwt. were exported, and in 1903 less than 150,000 cwt. As a rule each crew jointly owns its boat and tackle. The fishery is of ancient importance; at the old towns of Falsterbo and Skanör, south of Malmö, thousands of fishermen were employed until the harbours became choked in 1631, and the fish were a valuable item in the Hanseatic commerce. There are rich salmon-fisheries in the lower parts of the great northern rivers, especially the Torne, Kalix, Lule, Ångerman and Indal; in the Dal, the Klar and Göta, and several of the lesser rivers of the south. In the majority of rivers no special necessity has been found to protect the fishing. As a general rule the owner of the shore owns the river-fishing. The chief inspector of fisheries is a member of the board of agriculture.

Mining.—The iron-mining industry is of high importance, the output of iron ore forming by far the largest item in the total output of ores and minerals. Thus in 1902 the total output was nearly $3\frac{1}{2}$ million tons, of which 2,850,000 tons were iron ore. The output of iron ore has greatly increased; in 1870–1880 it averaged annually little more than one-quarter of the amount in 1902. The deposits of iron ore are confined almost wholly to the extreme north of Norrland, and to a midland zone extending from the south of the Gulf of Bothnia to a point north of Lake Vener, which includes the Dannemora ore fields in the eastern part. In Norrland the deposits at Gellivara have long been worked, with the assistance of a railway to the Bothnian port of Luleå, but in 1903 the northern railway was completed across the Norwegian frontier to Narvik on Ofoten Fjord, and the vast deposits at the hills of Kirunavara and Luossavara began to be worked. These deposits alone are estimated to have an extent exceeding one-quarter of the total ore fields worked in the country. The deposits are generally in pockets, and the thickness of the beds ranges from 100 to nearly 500 ft. at Kirunavara, up to 230 ft. at Gellivara, and in the midland fields generally from 40 to 100 ft., although at the great field of Grängesberg, in Kopparberg and Örebro Län, a thickness of nearly 300 ft. is found. Nearly all the ore is magnetite, and in the midlands it is almost wholly free of phosphorus. The percentage of iron in the ore is high, as much as 66% in the Kirunavara-Luossavara ore; and little less in that of Grängesberg; this far exceeds other European ores, though it is equalled by some in America. Sweden possesses little coal, and pig-iron is produced with charcoal only; its quality is excellent, but Sweden's proportion to the world's produce is hardly more than 1%, whereas in the 17th and 18th centuries, before the use of coal elsewhere, it was much greater. As an industry, however, the production both of pig-iron and of wrought iron and steel is increasingly prosperous. The ironworks and blast-furnaces are almost wholly in the midland districts. Copper has been mined at Falun since the 14th century; it is also produced at Åtvidaberg in Östergötland. The production, however, has greatly decreased. A little gold and silver are extracted at Falun, and the silver mines at Sala in Vestmanlands Län have been worked at least since the 16th century, but here again the output has decreased. Lead is produced at Sala and Kafveltorp, and zinc ore at Åmmeberg. Coal is found in small beds in Skåne, east and north of Helsingborg, at Billesholm, Bjuf and Höganäs; but the amount raised, although increasing, is only some 300,000 tons annually. Mining administration is in the charge of a special bureau of the board of trade. The Iron Institute (*Järnkontoret*) was established in 1748 as a financial institution, in which the chief iron-mining companies have shares, for the advancement of advantageous loans and the promotion of the industry generally. It maintains a special education and investigation fund. There are schools of mining at Stockholm (the higher school), Falun and Filipstad in Vermland.

Manufactures.—If the total value of the output of the manufacturing industries in Sweden be taken as 100, the following are the most important of those industries, according to the approximate percentage of each to the whole: iron industries 18·3, and mechanical works 4; saw-milling 12·5 and wood-pulp works 2·5; cloth-factories and spinning-mills 8; flour-mills 6·4; sugar-refining and beet-sugar works 6; spirit distilling and manufacture 4·7, and brewing 2·6; dairy products 4·4; papermaking 1·6; leaving a remainder of 29% for other industries. The total annual value of the output is about £72,000,000. The great mechanical works are found at or near Malmö, Stockholm, Jönköping, Trollhättan, Motala on Lake Vetter, Lund, Gothenburg, Karlstad, Falun and Eskilstuna, which is especially noted for its cutlery. A few other establishments including both mechanical workshops and ore-extraction works may be mentioned: Domnarfvet, on the Dal River, near Falun; Sandviken, near Gefle; and Bofors in Örebro Län. The principal centres of the textile industry are Norrköping in Östergötland and Borås in Elfsborg Län, where there are weaving schools; and the industry is spread over Elfsborg Län and the vicinity of Gothenburg. There is a linen industry in Småland and in the south of Norrland. One of the most notable special industries of Sweden is match-making, for which there are large works at Jönköping, Tidaholm in Skaraborg Län and in the neighbourhood of Kalmar. The centre of the beet-sugar industry is Skåne, but it is also carried on in the island of Gotland; its great access of prosperity is chiefly owing to the existence of a protective duty on imported sugar. Spirit distillation centres in Kristianstad Län. Among other industries may be mentioned the earthenware works at Höganäs at the north end of the Sound, the cement works of Lomma in this vicinity, and the pottery works of Rörstrand in, and Gustafsberg near, Stockholm; where beautiful ware is produced. Stone is worked chiefly in Göteborg och Bohus and Blekinge Län.

Commerce.—Exports approach £30,000,000 and imports £40,000,000 in average annual value.

Of the total exports that of timber, wrought and unwrought, represents 50%; the other principal exports with approximate percentage are: iron and steel 13·5, iron ore 3·6, machinery and implements 3·2, and other iron and steel goods 2·7; butter 10; paper 3·4; carpentry work 3; matches 2·3. The principal imports with percentage to the whole are: coal and coke 15, grain 8, coffee 4·6, machinery 4, wool, yarn, thread, cotton and woollen goods 9·4; hides and skins 2·5. Oil and fish are also important. The principal countries trading with Sweden are the United Kingdom (exports from Sweden 38·2%, imports to Sweden 25·7), Germany (exports 16%, imports 39) and Denmark (exports 14%, imports 12·5). Other countries with which Sweden has mainly an export trade are France, the Netherlands and Norway. With Russia on the other hand the trade is principally import. In the case of the United Kingdom, Germany, Denmark and Norway, the transit trade forms an important proportion of the whole. The coal imported (which forms over 90% of the whole consumed) comes mainly from Great Britain; while most of the colonial produce, such as coffee and tobacco, comes through Germany. The match and paper export trade is principally with the United Kingdom. Between 1865 and 1888 Sweden employed a modified system of free trade, but various enactments in 1888 and 1892 reintroduced methods of protection.

Shipping.—The total number of vessels in the Swedish commercial fleet is about 3000 of 650,000 tons register; of which steamers represent about 380,000 tons. On an average about 73,000 vessels, of an aggregate tonnage of 17,500,000, enter and clear the ports. The principal ports of register are Gothenburg, Stockholm, Helsingborg and Gefle, in order; though the principal commercial ports are Stockholm, Gothenburg and Malmö. Owing to the natural configuration of the coast and the skärgård excellent natural harbours are almost without number. Artificial harbours are consequently few, but those at Helsingborg, Malmö, Halmstad, Ystad and Kalmar may be mentioned. The principal docks are at Gothenburg, Stockholm, Malmö, Oskarshamn and Norrköping, besides the naval docks at Karlskrona; and the principal ports where large vessels can be accommodated on slips are Malmö, Gothenburg, Stockholm, Karlskrona and Gefle. A list of the chief ports may be conveniently classified. On the west coast north of Gothenburg are Strömstad, near the Norwegian frontier, and Uddevalla, on a deep inlet behind the island of Orust, 35 m. from the open Cattegat. South of Gothenburg on the open coast are Varberg and Halmstad; and on the Sound are the three large ports of Helsingborg, Landskrona and Malmö. Passing to the Baltic, Trelleborg and Ystad lie on the southernmost coast of the country, and Simrishamn, Åhus the outport of Kristianstad, Karlshamn, Ronneby and Karlskrona on the wide Hanö Bay. On Kalmar Sound are Kalmar and Oskarshamn; and continuing northward, Vestervik, Söderköping at the head of the inlet Slätbäken, Norrköping, similarly situated on Bråviken, and Stockholm, far within the skärgård. On the Bothnian coast there is a port at or near the mouth of each great river, where the timber floated down from the interior is both worked and exported. The chief ports here, from south to north, are: Gefle, Söderhamn, Hudiksvall, Sundsvall, Hernösand, Ornsköldsvik, Umeå, Skellefteå, Piteå and Luleå, the last exporting the ore from the northern iron-mines.

Banks.—The first Swedish bank, called the Palmstruch bank after its founder, Johan Palmstruch, was incorporated in 1656. It began to issue notes in 1661. It was shortly afterwards bankrupt, and in 1668 the Bank of Sweden (*Sveriges Riksbank*) succeeded it. This is managed by a board of seven delegates, the chairman being elected by the government, while the Riksdag (parliament) elects the remainder. It began to issue notes in 1701. This ability was shared by private banks with solidary responsibility until 1903, but under a reform of 1897 the riksbank took over, from 1904, the whole right of issuing paper currency, which is in wide use. The capital of the riksbank is 50,000,000 kronor (£2,250,000). The other banks are joint-stock banks and savings-banks, of which the first was opened at Gothenburg in 1820. The post office savings bank was opened in 1884.

Coinage.—The counting unit in the Swedish coinage is the *krona*, equal to 1·1 shilling. The monetary unit is 10 kronor gold, and gold pieces, not widely met with in circulation, are struck of 20, 10 and 5 kronor. The krona equals 100 *öre*. Silver pieces of 2 and 1 krona, 50, 25 and 10 öre are struck, and bronze pieces of 5, 2, and 1 öre. Sweden, Norway and Denmark have the same monetary system.

Finance.—In the budget for 1910 revenue and expenditure were estimated at £12,674,300. The principal sources of income in the ordinary revenue are railways, forests, telegraphs and rent from Crown lands; and those in the revenue voted (*bevillningar*), which is about seven-eighths of the whole, customs, the taxes on spirits and beet-sugar, and income from the post office. The departments to which the bulk of expenditure is devoted are those of the army, the interior, the navy and education. A large proportion of the army expenditure was formerly defrayed by a system of military tenure on certain lands. Land-taxes, however, were finally abolished in 1904, and their place was taken by an increased taxation on real estate, revised triennially, and by an income tax arranged on a sliding scale, up to 4% of the income (9·6 pence in the £), settled according to individual declaration. The national debt was practically nil until *c.* 1855, and the debt contracted thereafter owes its existence almost wholly to railway construction. It increased from about £2,300,000 in 1860 to £6,400,000 in 1870 and £18,600,000 in 1900. In 1904 it exceeded £19,000,000. The greater proportion of communal revenue comes from income and property tax, the sale of spirits under the Gothenburg System, and contributions from the treasury. Primary education, poor relief, and Church purposes form the principal items of expenditure.

Constitution and Government.—Sweden is a limited monarchy, the constitution resting primarily on a law (*regerings-formen*) of the 6th of June 1809. The king is irresponsible, and executive power is vested in him alone. All his resolutions, however, must be taken in the presence of the cabinet (*statsråd*). The cabinet councillors are appointed by the king and are responsible to the parliament (*Riksdag*). They are eleven in number, one being prime minister, two others consultative ministers, and the remaining eight heads of the departments of administration, which are justice, foreign affairs, land defence, naval defence, home affairs, finance, public works, agriculture. The councillors must be of Swedish birth and adherents of the Lutheran confession. The appointment of the majority of public officials is vested in the king, who can himself dismiss cabinet ministers and certain others, whereas in most cases a judicial inquiry is necessary before dismissal. The king shares legislative powers with the Riksdag, (parliament or diet), possessing the rights of initiation and absolute veto. He has also, in certain administrative and economic matters, a special legislative right.

The Riksdag consists of two chambers. The members of the first chamber are elected by the *landsthing*, or representative bodies of the *län*, and by the municipal councils of some of the larger towns. They number 150, and are distributed among the constituencies in proportion to population; the distribution being revised every tenth year. Eligibility necessitates Swedish birth, an age of at least 35 years, and the possession, at the time of election and for three years previously, either of real property to the value of 80,000 kronor (£4400), or an annual income on which taxes have been paid of 4000 kronor (£220). Members are unpaid. The members of the second chamber number 230, of whom 150 are elected from rural constituencies and 80 from towns. The members receive a salary of 1200 kronor (£66), and are elected for a period of three years by electors, or directly, according to the resolution of the electoral district. If a member retires during that period, or if the chamber is dissolved, succeeding members are elected for the remainder of the three years, and thus the house is wholly renewed at regular intervals, which is not the case with the first house. The franchise was for long extremely limited in comparison with other countries, but in 1907 universal manhood suffrage was introduced, after protracted dissension and negotiation between the two houses. Eligibility to the lower house necessitates possession of the elective franchise, an age of at least 25 years, and residence within the constituency. Both chambers have in theory equal power. Before bills are discussed they may be prepared by committees, which play an important part in the work of the house. The agreement of both chambers is necessary before a bill becomes law, but when they differ on budget questions the matter is settled by a common vote of both, which arrangement gives the second chamber a certain advantage from the greater number of its members. By revisers elected annually the Riksdag controls the finances of the kingdom, and by an official (*justitieombudsman*) elected in the same way the administration of justice is controlled; he can indict any functionary of the state who has abused his power. The bank of the kingdom is superintended by trustees elected by the Riksdag, and in the same way the public debt is administered through an office (*riksgäldskontoret*), whose head is appointed by the Riksdag.

Local Government.—For the purposes of local government Sweden is divided into 25 administrative districts called *län*, a list of which is given in the paragraph dealing with population. The elected representative body in each is the *landsthing*, which deliberates on the affairs of the län and has a right to levy taxes. The chief official of the län is the *landshöfding*, under whom are secretarial and fiscal departments. Privileged towns, receiving their privileges from the government (not necessarily on the basis of population), are under a mayor (*borgmästare*) and aldermen (*rådmän*), the aldermen being elected by the citizens, while the mayor is appointed by the government from the first three aldermen on the poll, is paid, and holds office for life. Gothenburg has two mayors, and the city of Stockholm (*q.v.*), a län in itself, has a special form of government. The major rural divisions are the *fögderier*, under bailiffs, a subdivision of which is the *länsmansdistrikt* under a *länsman*.

Justice.—Justice is administered by tribunals of three instances. (1) There are 119 rural judicial districts (*domsagor*), which may be subdivided into judicial divisions (*tingslag*). Each *tingslag* has a court (*häradsrätt*), consisting of a judge and twelve unpaid assessors (*nämndemän*), of whom seven form a quorum, elected by the people. These, if unanimously of a different opinion to the judge, can outvote him. The town-courts in the privileged towns are called *rådstufvurätter*, and consist of the mayor and at least two aldermen. (2) There are three higher courts (*hofrätter*), in Stockholm, Jönköping and Kristianstad. (3) The Supreme Court (*Högsta Domstolen*) passes sentences in the name of the king, who is nominally the highest judicial authority. The court has a membership of 18 justices (*justitieråd*), two of whom are present in the council of state when law questions are to be settled; while the body also gives opinion upon all proposed changes of law.

Army and Navy.—General military service is enforced. Every Swedish man belongs to the conscripts (*värnpligtige*) between the age of 21 and 40, during which time he serves eight years in the first levy, four in the second, and eight in the reserves. The conscripts were formerly trained for 90 days, but according to the law of 1901, the conscript is bound to serve in time of peace—in the infantry, position artillery, fortress artillery, fortress engineers, and the army service corps a total of 240 days; and in the cavalry, field artillery, field engineers, and field telegraph corps a total of 365 days. The permanent cadres number about 22,000, and about 85,000 men are annually trained as recruits or recalled for further training. The organization of the army in time of peace is as follows: 82 battalions of infantry (28 regiments), 50 squadrons of cavalry, 71 field artillery and 7 position artillery batteries, 10 fortress artillery, 16 engineer, and 18 army service corps companies. There are six divisions, quartered at Helsingborg, Linköping, Sköfde, Stockholm (two), and Hernösand; in addition to the Gotland troops quartered at Visby. A division in time of war would probably consist of 2 battalions of infantry (4 regiments, 12 battalions), with 4 squadrons of cavalry, 1 artillery regiment, 1 company of engineers, &c. A cavalry division would consist of 2 brigades of 8 squadrons each, and 1 brigade of horse artillery. It is estimated that 500,000 men are available for service in the various capacities in case of war. There are fortresses at Stockholm (Vaxholm and Oscar-Fredriksborg), Boden on the northern railway near the Russian frontier, Karlsborg on Lake Vetter, and Karlskrona; and there are forts at Gothenburg and on Gotland. The reforms of 1901 abolished the *indelta*, a body including both infantry and cavalry who lived in various parts of the country, in some cases having their houses provided for them. This peculiar system of military tenure (*indelningsverket*) originated in the 17th century, when certain landowners were exempt from other military obligations if they provided and maintained armed men. The navy is small, including 11 ironclads of 3100 to 3650 tons. The personnel consists of a cadre, reserve and about 17,000 conscripts. It also includes two coast-artillery regiments, with headquarters at Vaxholm and Karlskrona. The principal naval station is Karlskrona, and there is another at Stockholm.

Religion.—More than 99% of the total population belong to the Swedish Lutheran Church, of which the king is the supreme head. Sweden is divided into 12 dioceses and 186 deaneries, the head of the diocese of Upsala being archbishop. The parish is an important unit in secular as well as ecclesiastical connexions. The rector presides over the local school board, which is appointed by the church assembly (*kyrkostämman*), and thus an intimate relation between the church and education has long been maintained. A peculiar duty of the clergy is found in the *husförhör* or meetings designed to enable the priest to test and develop the religious knowledge of his parishioners by methods of catechism. It was formerly enjoined upon the clergy to visit parishioners for this purpose, and the system is still maintained in the form of meetings, which have in some cases, however, acquired a character mainly devotional. The parishes number 2556, but one living may include more than one parish. In the sparsely inhabited districts of the north the parish is sometimes of enormous extent, thus that of Gellivara has an area of about 6500 sq. m. In such cases the priest often makes protracted journeys from farm to farm through his parish, and on certain occasions the congregation at his church will include many, both Swedes and Lapps, who have travelled perhaps for several days in order to be present. Dissenters are bound to contribute to the maintenance of the Swedish Church, in consideration of the secular duties of the priests.

Education.—The connexion between the church and education is so close that the control of both is vested in a single department of the government. Primary education is carried on in common schools of different grades, under both local and state inspection, the parish being the school district. Seminaries are maintained for common school teachers, with a four years' course. At Haparanda and Mattisudden in Norbotten there are special institutions for teachers for the Finnish and Lapp population respectively. Wide attention was attracted to Swedish educational methods principally by the introduction of the system of Sloyd (*slöjd*), initiated at the Nääs seminary near Gothenburg, and concerned with the teaching of manual occupations, both for boys and for girls. The higher education of the people is provided by people's high schools in the rural districts, especially for the peasantry, maintained by the county councils, agricultural societies and the state, and providing a two years' course both in general education and in special practical subjects according to local needs. The men's course is held in winter; and a women's course, in some instances, in summer. The workmen's institutes in the towns have a similar object. A system of university extension has been developed on the English pattern, summer courses being held at Upsala and Lund. In connexion with the army reform of 1901 a system of army high schools was proposed for conscripts while serving. Technical education is provided in higher schools at Stockholm, Gothenburg and certain other large industrial centres; and in lower schools distributed throughout the country, in which special attention is given to the prevailing local industries. The agricultural and forestry schools have been mentioned in the paragraphs on these subjects. Public schools for boys are provided by the state, each bishop being superintendent (*eforus*) of those in his diocese. In the three lowest classes (out of a total of nine) a single system of instruction is practised; thereafter there are classical and scientific sides. Greek is taught only in a section of the upper classical classes. Of modern languages, German is taught throughout; English in all classes of the scientific side, and the upper classical classes. Much attention is paid to singing, drill and gymnastics. The school terms together occupy 34½ weeks in the year. At the schools examinations are held for entrance to the universities and certain higher special schools. Owing to the high development of state public schools, private schools for boys are few; but higher schools for girls are all private, excepting the higher seminary for teachers and the state normal school at Stockholm. The state universities are at Upsala and Lund, and with these ranks the Caroline Medical Institution at Stockholm. There are universities (founded by private individual benefactions, but under state control) at Stockholm and Gothenburg. The faculties at Upsala and Lund are theology, law, medicine and philosophy (including both art and science). The courses are long, ranging from six to nine years; and the degrees are those of candidate, licentiate and doctor. The students, who are distinguished by their white caps, are divided for social purposes into "nations" (*landskap*) of ancient origin, based upon the distinctions between natives of different parts.

Scientific Institutions.—Among the scientific and literary societies are to be noted the Swedish Academy, consisting of 18 members, which was instituted in 1786 by Gustavus III., after the pattern of the Académie Française, for the cultivation of the Swedish language and literature; and the Academy of Science, founded in 1739 by Linnaeus and others for the promotion of the natural sciences. The first distributes one and the second two of the prizes of the Nobel Foundation. A fourth prize is distributed by the Caroline Institution at Stockholm. There may be mentioned further the Royal Academies of Literature, History and Antiquities (1786), of Agriculture (1811), of Arts (1735) and of Music (1771). The principal museums and art and other collections are in Stockholm, Upsala and Lund, and Gothenburg. The Royal Library in the Humlegård Park at Stockholm, and the university libraries at Upsala and Lund are entitled to receive a copy of every publication printed in the kingdom. Certain of the large towns have excellent public libraries, and parish libraries are widely distributed.

See *Sweden, its People and its Industry*, a government publication (ed. G. Sundbärg) dealing with the land and people in every aspect (Eng. vers., Stockholm, 1904); *Bidrag till Sveriges officiela statistik* (Stockholm, 1857 seq.); *Statistisk Tidskrift*, periodically from 1862; Publications (year-book, guides, &c.) of the *Svenska Turistföreningen* (Swedish Touring Club) Stockholm; periodical *Bulletin* of the Geological Institute of Upsala University, in which may be noted K. Ahlenius, *Beiträge zur Kenntniss der Seenkettenregion in Schwedisch-Lappland*, No. v. (1900); Also Dahlman, *Inledning til Sveriges physikalska geografi* (Stockholm, 1857); *Statistiskt Lexicon ofrer Sverige* (Stockholm, 1859–1870); M. Höjer, *Konungariket Sverige* (Stockholm, 1875–1883); C. Almqvist, *La Suède, ses progrès sociaux* (Stockholm, 1879); P. B. Du Chaillu, *The Land of the Midnight Sun* (London, 1881); C. M. Rosenberg, *Geografiskt-statistiskt handlexicon öfrer Sverige* (Stockholm, 1882–1883); W. W. Thomas, *Sweden and the Swedes* (Chicago and New York, 1891); Healey, *Educational Systems of Sweden, Norway and Denmark* (London, 1893); Nyström, *Handbok i Sveriges geografi* (Stockholm, 1895), and *Sveriges rike* (Stockholm, 1902); G. Andersson, *Geschichte der Vegetation Schwedens* (Leipzig, 1896); K. Ahlenius, *Sverige, geografisk, topografisk, statistisk beskrifning* (Stockholm); and for geology, A. G. Nathorst, *Sveriges geologi* (Stockholm). For more detailed accounts of the various districts see the publications of the *Sveriges Geologiska Undersökning*, and also the volumes of the *Geologiska Föreningens i Stockholm Förhandlingar*. (O. J. R. H.)

History

Remains dating from the Stone Age are found scattered over the southern half of Sweden, but it is only along the south coast and in the districts bordering on the Cattegat that they occur in any considerable quantity. The antiquities of the Bronze Age are much more widely distributed and reach as far as the north of Helsingland. It is evident that the country must at this time have been fairly populous. So far as can be judged from the human remains found the population in general in both the Stone and Bronze Ages seems to have been similar in type to that of the present day, and there is no clear evidence for the advent of a new race. The Iron Age probably began in the south of Sweden at any rate some three or four centuries before the beginning of the Christian era. (See further SCANDINAVIAN CIVILIZATION.)

Early Races and Divisions.

The first historical notice relating to Sweden is contained in Tacitus, *Germania*, cap. 44. This book was probably published in A.D. 98 or 99 and in the passage mentioned we find the name of the chief people of the peninsula, the Swedes proper, Suiones (O. N. *Sviar*, Swed. *Svear*, A. S. *Sweon*), who eventually gave their name to the whole country. According to Tacitus they were governed by a king whose power was absolute and comprehensive, and possessed a strong fleet which secured them from the fear of hostile incursions. Hence arms were not borne in times of peace but stored away under charge of a slave, and Tacitus suggests in explanation that the royal policy did not commit this trust to noble, freeman or freedman. Their original territories lay on both sides of the Mälar, in the provinces later known as Upland, Södermanland and Westmanland. Tacitus mentions another tribe, the Sitones, which he places next to the Suiones, but they have not been identified, and it is not clear from his description whether they lived within the peninsula or not. The only information he gives about them is that they were ruled over by a woman. Other early Roman writers, Mela and Pliny, mention the country under the name Scandinavia (Skåne), a name which in native records seems always to have been confined to the southernmost district in the peninsula. Little information, however, is given by these authorities with regard to the inhabitants.

The people next in importance to the Suiones in the peninsula (Swed. *Götar*, O. N. *Gautar*, A. S. *Geatas*) are first mentioned by Ptolemy (under the form Goutai for Gautoi), together with a number of other tribal names, most of which unfortunately cannot be identified, owing to the corrupt state of the text. Ptolemy puts the Götar in the southern part of the country, and from the earliest historical times their name has been given to the whole region between the Cattegat and the Baltic, exclusive of the provinces of Halland and Skåne which down to the 17th century always belonged to Denmark. The coast of the Cattegat north of the Göta Elv was reckoned in Norway. Götaland consisted of the provinces of Vestergötland and Östergötland divided from one another by Lake Vetter, together with Småland. In early times Vestergötland seems to have been by far the most important.

Vermland, the district to the north of Lake Vener and the whole of the country to the north of Svealand seem to have been of small importance. Jämtland was always considered a part of Norway. After the time of Ptolemy we hear no more of Sweden until the 6th century, when a surprisingly full account of its peoples is given by the Gothic historian Jordanes. He mentions both the Svear (Swethans) and the Götar together with other peoples, the names of several of which can be recognized in the district—names of later times, in spite of the numerous corruptions of the text. He praises the horses of the Svear and speaks of their great trade in furs of arctic animals which were transferred from merchant to merchant until they reached Rome. About the other peoples of Sweden he gives a few details, chiefly of physical or moral characteristics, commenting upon the warlike nature of the Visigauti, the mildness of the Finns, the lofty stature of the Vinovii and the meat and egg diet of the Rerefennae. Jordanes's statement regarding the prevalence of trade with Sweden is corroborated by the fact that many coins and bracteates of the period have been found in the country. Of these the coins are chiefly Roman and Byzantine gold pieces of the 5th century, the bracteates copies of Roman coins of the same period.

Account of Jordanes.

Procopius, the contemporary of Jordanes (*Gothica*, ii. 15) likewise gives an account of Sweden, which he calls Thule, but the only tribes which he names are the Skrithephinnoi (A. S. Scriðefinnas), a wild people of Finnish stock, and the Götar (Gautoi) whom he describes as a "nation abounding in men." For the same period we derive a considerable amount of information with regard to Swedish affairs from the Anglo-Saxon poem *Beowulf*. The hero himself belonged to the Greatas (*i.e.* in all probability Götar, though the identification is disputed by some scholars), his mother being the daughter of their king Hrethel. Haethcyn, the son and successor of this Hrethel, is said to have perished in a disastrous battle against the Svear, but his fall was avenged by his brother Hygelac in a subsequent engagement in which the Swedish king Ongentheow was killed. This Hygelac is clearly identical with that Chochilaicus wrongly described as a Danish king by Gregory of Tours (iii. 3) who made a piratical expedition to the lower Rhine which ended in his defeat aud death in a battle with the Franks under Theodberht about A.D. 520. The poem contains several allusions to this disaster. We learn further that about the time of Hygelac's death strife broke out in the royal family of the Svear, between Onela, the son and successor of Ongentheow, and Eanmund and Eadgils, the sons of his brother Ohthere. The latter fled for protection to the Götar and the war which ensued cost the lives of Eanmund and of Heardred the son and successor of Hygelac. According to the poem Beowulf himself now became king of the Götar and assisted Eadgils in a campaign which resulted in the death of Onela and the acquisition of the throne by his nephew. What is said in the poem with regard to the end of Beowulf belongs to the realm of myth, and for three centuries after this time we have no reference to Swedish affairs in English or other foreign authorities. Moreover after the time of Beowulf and Jordanes there are very few references to the kingdom of the Götar and in Olaf Sköttkonung's time it was merely an earldom. The kingdom must have come to an end between the 6th and 10th centuries A.D., and probably quite early in that period.

Beowulf.

The Ynglingatal, a poem said to have been composed by Thioðolfr of Hvín, court-poet of Harold Fairhair, king of Norway, gives a genealogy of Harold's family, which it carries back to the early kings of the Svear. Snorri Sturluson (1178–1241) the Icelandic author using this poem as a basis and amplifying it from other sources, wrote the Ynglinga Saga, which traces back the history of the family, generation by generation, to its beginning. In this saga Aðils (the Eadgils of *Beowulf*), son of Ottarr is one of the most prominent figures. The account given of him agrees in general with the statements in *Beowulf*, though the nature of his relations with Ali (Onela) has been misunderstood. The decisive battle between the two kings is said to have taken place on the frozen surface of Lake Wener. Ongentheow appears to have been entirely forgotten in Norse tradition and his place is taken by a certain Egill. The saga further states that Aðils was an enthusiastic horse-breeder and that he met with his death through a fall from his horse. This point is of interest in connexion with the notice of Jordanes, mentioned above, with regard to the horses of the Svear. Other northern authorities such as Saxo and the Hrolfs Saga Kraka represent Aðils in a very unfavourable light as niggardly and addicted to sorcery.

The Ynglingatals and Ynglinga Saga.

The Ynglingatal and Ynglinga Saga enumerate Aðil's ancestors to no less than seventeen generations, with short accounts of each. We have no means of checking the genealogy from other sources, and the majority of the characters are probably to be regarded as mythical. The origin of the family is traced to the god Frey, son of Niörðr, who is said to have founded Upsala, the ancient capital of Sweden. His reign is represented as a golden age of peace and prosperity and the great wealth of the sanctuary is said to have taken its beginning from the offerings at his tomb. His full name appears to have been Yngvifreyr or Ingunar Freyr and his descendants are collectively termed Ynglingar, though we also occasionally meet with the name Skilfingar, which corresponds with the name Scilfingar borne by the Swedish royal family in *Beowulf*.

After the time of Aðils the Ynglingar remained in possession of Upsala for four generations according to the saga. Ultimately the treachery and the murderous disposition of the king named Ingialdr led to his overthrow by a prince from Skåne, called Ivarr Viðfaðmi. His son Olafr Trételgia withdrew to Vermland, which he brought into a state of cultivation, though he was subsequently sacrificed by his subjects in a time of famine. It is stated in the saga that the Swedish kings were believed to have control over the seasons like their ancestor, the god Frey, and traces of this belief seem to have lingered in the country down to the times of Gustavus Vasa. The sons of Olafr Trételgia moved westward into Norway, and if we may trust the saga, the Swedish kingdom never again came into the possession of their family.

The subsequent kings of Sweden are said to have been descended from Ivarr Viðfaðmi. The most prominent figures in this family are Haraldr Hilditönn Ivarr's grandson and his nephew Sigurðr Hringr. The story of the battle between these two at Bråvik, in which Haraldr lost his life, is one of the most famous in northern literature. But the position of these kings with regard to Sweden is far from clear. Their home is probably to be placed on the Cattegat rather than on the Baltic. The same is true also of Ragnarr Loðbrók, who is said to have been the son of Sigurðr Hringr. About the year 830 the missionary bishop Ansgar made his first expedition to Sweden. He made his way to Birca on the Mälar. The king whom he found reigning there is called Björn (Bern) and is generally identified with the king Björn for whom Bragi the Old composed the poem called *Ragnarsdrápa*. On his subsequent journeys to Sweden Ansgar encountered kings called Olafr and Önundr. He appears to have met with considerable immediate success in his missionary enterprises, although there is no evidence to show that the churches he founded long survived his death, and no serious mission seems to have been attempted for more than a century afterwards.

Introduction of Christianity.

During the 9th century extensive Scandinavian settlements were made on the east side of the Baltic, and even as early as the reign of Louis I. we hear of piratical expeditions on the Black Sea and on the Caspian. The famous expeditions of Rurik and Askold which resulted in the origin of the Russian monarchy appear to have taken place towards the middle of the 9th century, but it has not been found possible to connect these names with any families known to us from Swedish tradition. Proofs of extensive Scandinavian settlement in Russia are to be found partly in the Russian names assigned to the Dnieper rapids by Constantine Porphyrogenitus, partly in references to this people made by foreign representatives at the court of Byzantium. The fact that many of the names which occur

Scandinavian Settlements in Russia.

in Russian chronicles seem to be peculiarly Swedish suggests that Sweden was the home of the settlers, and the best authorities consider that the original Scandinavian conquerors were Swedes who had settled on the east coast of the Baltic.

In the time of Harold Fairhair, probably about the beginning of the 10th century, we hear of a king named Eric the son of Emund at Upsala, whose authority seems to have reached as far as Norway. Later in the century there is record of a king named Björn á Haugi who is said to have been the son of Eric and to have reigned fifty years. Björn's sons and successors were Olaf and Eric the Victorious. Styrbiörn Starki, the son of Olaf, being refused his share of the government by Eric after his father's death, made himself a stronghold at Jomsborg in Pomerania and spent some years in piratical expeditions. Eventually he betook himself to Harold Bluetooth, then king of Denmark, and endeavoured to secure his assistance in gaining the Swedish throne by force of arms. Although he failed in this attempt he was not deterred from attacking Eric, and a battle took place between the two at the Fyriså (close to Upsala) in which Styrbiörn was defeated and killed. Eric himself died ten years after this battle, apparently about 993. According to the story he had obtained victory from Odin in return for a promise to give himself up at the end of ten years. Under his son and successor Olaf, surnamed Sköttkonung, Christianity was fully established in Sweden. Olaf Tryggvason, the king of Norway, had married his sister Ingibiörg to Ragnvald, earl of Vestergötland, on condition that he should receive baptism, and the Swedish king's wife was also a Christian, though he himself was not baptized until 1008 by Sigfrid at Husaby. A quarrel arose in the last years of the 10th century between Olaf Sköttkonung and Olaf Tryggvason. The latter had applied for the hand of Sigrið, the widow of Eric the Victorious, but had insulted her on her refusal to become a Christian. In the year 1000, when the Norwegian king was in Pomerania, a coalition was formed between the king of Sweden, Sweyn Forkbeard, king of Denmark, and earl Eric of Lade, and the allies waylaid their enemy off the coast near Rügen and overthrew him in the great sea-battle of Svolder. Under Olaf Sköttkonung Sweden became the mightiest of the kingdoms of the north, in spite of the king's own inactivity. She lost her lands east of the Baltic, but received as compensation in Norway part of Trondhjem and the district now called Bohüslan. These lands Olaf handed over to Earl Sweyn, brother of Earl Eric (whose father Haakon had governed Norway), as a marriage portion for his daughter Holmfrið. Some years later we hear of hostilities between Olaf Sköttkonung and another Norwegian prince, Olaf Haraldsson (the Fat), who raided Sweden and was besieged in the Mälar by the Swedish king. In 1014, the year of Earl Eric's departure to England with Canute, Olaf Haraldsson, returning to Norway as king, put an end to the Swedish and Danish supremacy, and in 1015 he forced Earl Sweyn to leave the country. Trifling border-quarrels followed, but in 1017 a truce was arranged between Norway and Vestergötland, where Earl Ragnvald was still in power. Olaf of Norway now sent his marshal Björn to Ragnvald to arrange a peace. Ragnvald brought him to a great assembly at Upsala in February 1018. At this meeting Björn, supported by the earl, asked for peace, and Olaf was compelled by the pressure of the lawman Thorgny to agree to this and also to promise his daughter Ingegerð in marriage to the Norse king. The marriage, however, never got beyond the betrothal stage, and at Earl Ragnvald's suggestion Astrid, her half-sister, was substituted, contrary to the will of Olaf Sköttkonung. Such was the anger of the king that Ragnvald was forced to accompany Ingegerð to Russia, where she was married to the grand-duke Jaroslav at Novgorod. In Sweden, however, both the Vestgötar and the Upland Sviar were discontented, the former on account of the breaking of the king's promise to Olaf of Norway and the latter on account of the introduction of the new religion, and their passions were further inflamed by the lawman Anund of Skara. A rising in Upland compelled Olaf to share his power with his son Jacob, whose name was changed to Anund by the leaders of the revolt. A meeting was then arranged between the kings of Norway and Sweden at Kongelf in 1019, and this resulted in a treaty. The death of Olaf Sköttkonung is assigned by Snorri Sturluson to the winter of 1021–1022. His grave is still shown at Husaby in Vestergötland.

Kings in the 10th Century.

Establishment of Christianity.

Reign of Olaf Sköttkonung.

Anund, now sole king, early in his reign allied himself with Olaf Haraldsson against Canute of Denmark, who had demanded the restitution of the rights possessed by his father Sweyn in Norway. The allies took advantage of the Danish king's absence to harry his land. On his return an indecisive battle was fought at Helgi Å, and Anund returned to Sweden. Olaf was driven from Norway by the Danes, but returning in 1030 he raised a small army in Sweden and marched through Jämtland to Trondhjem only to meet his death at the battle of Stiklestad. After death he was worshipped in Sweden, especially in Götland. We hear from Adam of Bremen that Anund was young in years but old in wisdom and cunning; he was called Kolbrännea because he had the houses of evildoers burnt. Like Olaf Sköttkonung he caused coins to be struck at Sigtuna, of which a few remain. The moneyers' names are English. The coins of Anund surpass all that were struck during the next two centuries. He appears to have died about 1050, according to Adam of Bremen. He was succeeded by his brother Emund the Old, who had been previously passed over because his mother was unfree, the daughter of a Slav prince and captured in war. This king had become a Christian, but soon quarrelled with Adalhard, archbishop of Bremen, and endeavoured to secure the independence of the Swedish church, which was not obtained for another century. Emund, who was given the name Slemme, had territorial disputes with Denmark in the early part of his reign. These disputes were settled by a rectification of boundaries which assigned Blekinge to Denmark.

King Anund, c. 1022–c. 1050.

Emund the Old, 1050–1060.

With the death of Emund, which took place in 1060, the old family of Swedish kings dies out. The successor of Emund the Old was a king named Steinkel who had married the daughter of his predecessor. He was the son of a certain Ragnvald, perhaps connected with the Vestergötland Ragnvald, of the reign of Olaf Sköttkonung. Steinkel was born in Vestergötland and was warmly attached to the Christian religion. The Adalhard who had quarrelled with Emund the Old now sent a bishop, Adalhard the younger, to Scara. Christianity was by this time firmly established throughout most of Sweden, its chief strength being in Vestergötland. The Uplanders, however, still held out against it, and Adalhard, though he succeeded in destroying the idols in his own district Vestergötland, was unable to persuade Steinkel to destroy the old sanctuary at Upsala. During his reign grants of land in Vermland made by the king to the Norse earl Haakon Ivarsson led to a successful invasion of Götaland by Harold Hardrada of Norway. Steinkel also had disputes with Denmark. On his death in 1066 a civil war broke out in which the leaders were two obscure princes named Eric. Probably the division of feeling between Vestergötland and Upland in the matter of religion was the real cause of this war, but nothing is known of the details, though we hear that both kings as well as the chief men of the land fell in it.

Steinkel, 1060–1066.

A prince called Haakon the Red now appears as king of Sweden and is said to have occupied the throne for thirteen years. In the Vestergötland regnal lists he appears before Steinkel and it is possible that the authority of that king was not regularly acknowledged in the province. In 1081 we find the sons of Steinkel, Inge and Halstan, reigning in Sweden. Inge's attachment to Christianity caused him to be expelled after a short time by his brother-in-law Sweyn or Blotsweyn, so called from his revival of the old sacrifices. Sweyn retained the kingship only for three years. After that interval Inge returned and slew him, and his fall marks the final overthrow of the old religion.

Haakon the Red, 1066–1079?

Halstan, Inge and Blotsweyn.

The interesting account of Upsala preserved by Adam of

Bremen in his *History* (iv. 26) apparently dates from the period immediately preceding these events. He describes the temple as one of great splendour and covered with gilding. In it stood the statues of the three chief deities Thor, Odin and Fricco (by whom he probably means Frey). Every nine years a great festival was held there to which embassies were sent by all the peoples of Sweden. A large number of animals and even men were sacrificed on such occasions. In the neighbourhood of the temple was a grove of peculiar sanctity in which the bodies of the victims were hung up. After the introduction of Christianity the importance of Upsala began steadily to decline, and owing to its intimate associations with the old religion the kings no longer made it their residence.

Temple at Upsala.

(F. G. M. B.)

Under Blotsweyn's grandson, King Sverker (1134–1155), who permanently amalgamated the Swedes and Goths (each of the two nations supplying the common king alternately for the next hundred years), Sweden began to feel the advantage of a centralized monarchical government. Eric IX. (1150–1160) organized the Swedish Church on the model prevalent elsewhere, and undertook a crusade against the heathen Finlanders, which marks the beginning of Sweden's overseas dominion. Under Charles VII.,[1] the archbishopric of Upsala was founded (1164). But the greatest medieval statesman of Sweden was Earl Birger, who practically ruled the land from 1248 to 1266. To him is attributed the foundation of Stockholm; but he is best known as a legislator, and his wise reforms prepared the way for the abolition of serfdom. The increased dignity which the royal power owed to Earl Birger was still further extended by King Magnus Ladulås (1275–1290). Both these rulers, by the institution of separate and almost independent duchies, attempted to introduce into Sweden a feudal system similar to that already established elsewhere in Europe; but the danger of thus weakening the realm by partition was averted, though not without violent and tragic complications. Finally, in 1319, the severed portions of Sweden were once more reunited. Meanwhile the political development of the state was steadily proceeding. The formation of separate orders, or estates, was promoted by Magnus Ladulås, who extended the privileges of the clergy and founded an hereditary nobility (Ordinance of Alsnö, 1280). In connexion with this institution we now hear of a heavily armed cavalry as the kernel of the national army. The knights too now became distinguishable from the higher nobility. To this period belongs the rise of a prominent burgess class, as the towns now began to acquire charters. At the end of the 13th century, and the beginning of the 14th too, provincial codes of laws appear and the king and his council execute legislative functions.

Organization of the Kingdom.

Separation of the Estates.

Nobles and Burghers.

The first union between Sweden and Norway occurred in 1319, when the three-year-old Magnus, son of the Swedish royal duke Eric and of the Norwegian princess Ingeborg, who had inherited the throne of Norway from his grandfather Haakon V., was in the same year elected king of Sweden (Convention of Oslo). A long minority weakened the royal influence in both countries, and Magnus lost both his kingdoms before his death. The Swedes, irritated by his misrule, superseded him by his nephew, Albert of Mecklenburg (1365). In Sweden, Magnus's partialities and necessities led directly to the rise of a powerful landed aristocracy, and, indirectly, to the growth of popular liberties. Forced by the unruliness of the magnates to lean upon the middle classes, the king summoned (1359) the first Swedish *Riksdag*, on which occasion representatives from the towns were invited to appear along with the nobles and clergy. His successor, Albert, was forced to go a step farther and, in 1371, to take the first coronation oath. In 1388, at the request of the Swedes themselves, Albert was driven out by Margaret, regent of Denmark and Norway; and, at a convention of the representatives of the three Scandinavian kingdoms held at Kalmar (1397), Margaret's great-nephew, Eric of Pomerania, was elected the common king, but the liberties of each of the three realms were expressly reserved and confirmed. The union was to be a personal, not a political union.

First Union with Norway.

Union of Kalmar, 1397.

Neither Margaret herself nor her successors observed the stipulation that in each of the three kingdoms only natives should hold land and high office, and the efforts of Denmark (at that time by far the strongest member of the union) to impose her will on the weaker kingdoms soon produced a rupture, or, rather, a series of semi-ruptures. The Swedes first broke away from it in 1434 under the popular leader Engelbrecht, and after his murder they elected Karl Knutsson Bonde their king under the title of Charles VIII. (1436). In 1441 Charles VIII had to retire in favour of Christopher of Bavaria, who was already king of Denmark and Norway; but, on the death of Christopher (1448), a state of confusion ensued in the course of which Charles VIII. was twice expelled and twice reinstated. Finally, on his death in 1470, the three kingdoms were reunited under Christian I. of Denmark, the prelates and higher nobility of Sweden being favourable to the union, though the great majority of the Swedish people always detested it as a foreign usurpation. The national party was represented by the three great *Riksföreståndare*, or presidents of the realm, of the Sture family (see STURE), who, with brief intervals, from 1470 to 1520 successively defended the independence of Sweden against the Danish kings and kept the national spirit alive. But the presidentship was too casual and anomalous an institution to rally the nations round it permanently, and when the tyranny of Christian II. (*q.v.*) became intolerable the Swedish people elected Gustavus Eriksson Vasa, who as president had already driven out the Danes (see DENMARK: *History*), king of Sweden at Strengnäs (June 6, 1523).

First Breach of the Union, 1436.

Election of Gustavus Vasa, 1523.

The extraordinary difficulties of Gustavus (see GUSTAVUS I.) were directly responsible for the eccentric development, both political and religious, of the new kingdom which his genius created. So precarious was the position of the young king, that he was glad to make allies wherever he could find them. Hence his desire to stand well with the Holy See. Only three months after his accession, he addressed letters to the pope begging him to appoint new bishops "who would defend the rights of the Church without detriment to the Crown." He was especially urgent for the confirmation of his nominee Johannes Magni as primate, in the place of the rebellious archbishop Gustavus Trolle, who as a convicted traitor had been formally deposed by the Riksdag and was actually an outlawed exile. If the pope would confirm the elections of his bishops, Gustavus promised to be an obedient son of the Church. Scarcely had these letters been despatched when the king received a papal bull ordering the immediate reinstatement of Gustavus Trolle. The action of the Curia on this occasion was due to its conviction of the imminent triumph of Christian II. and the instability of Gustavus's position. It was a conviction shared by the rest of Europe; but, none the less, it was another of the many blunders of the Curia at this difficult period. Its immediate effect was the loss of the Swedish Church. Gustavus could not accept as primate an open and

Gustavus I., 1523–1560.

[1] A legendary list of kings gives to this Charles six predecessors of the same name. Subsequent kings of Sweden have always given this Charles the title of Charles VII.

determined traitor like Trolle. He publicly protested, in the sharpest language, that unless Johannes Magni were recognized at Rome as archbishop of Upsala, he was determined, of his own royal authority, henceforward to order the affairs of the Church in his realm to the glory of God and the satisfaction of all Christian men. But the Holy See was immovable, and Gustavus broke definitely with Rome. He began by protecting and promoting the Swedish reformers Olavus and Laurentius Petri, and Laurentius Andreae. The new teaching was allowed to spread, though at first unostentatiously and gradually. A fresh step in the direction of Lutheranism was the translation of the New Testament into Swedish, which was published in 1526. Simultaneously, a systematic attack was made upon the religious houses, beginning with the sequestration of the monastery of Gripsholm in January 1526. But the affair caused such general indignation that Gustavus felt obliged, in May, to offer some justification of his conduct. A few months later there was an open rupture between the king and his own primate, who ultimately was frightened into exile by a sudden accusation of treason. But the other bishops were also against Gustavus, and, irritated by their conscientious opposition, the king abandoned the no longer tenable position of a moderator and came openly forward as an antagonist. In 1526 the Catholic printing-presses were suppressed, and two-thirds of the Church's tithes were appropriated to the payment of the national debt. On the 18th of February 1527 two bishops, the first martyrs of Catholicism in Sweden, were gibbeted at Stockholm after a trial which was a parody of justice. This act of violence, evidently designed to terrorize the Church into submission, was effectual enough, for at the subsequent Riksdag of Vesterås (June, 1527), the bishops durst not even present a protest which they had privately prepared, and the assembly itself was bullied into an absolute submission to the royal will. The result was the Vesterås Recess which transferred all ecclesiastical property to the Crown. By the subsequent Vesterås Ordinance the Swedish Church was absolutely severed from Rome. Nevertheless, the changes so made were mainly administrative. There was no modification of doctrine, for the general resolution that God's Word should be preached plainly and purely was not contrary to the teaching of the ante-Tridentine Church. Even at the synod of Örebro, summoned in February 1529, "for the better regulation of church ceremonies and discipline according to God's Word," there was no formal protest against Rome; and the old ritual was retained for two years longer, though it was to be explained as symbolical. Henceforth the work of the Reformation continued uninterruptedly. In 1531 Laurentius Petri was elected the first Protestant primate of Sweden. Subsequently matters were much complicated by the absolutist tendencies of Gustavus. From 1539 onwards there was a breach between him and his own prelates in consequence of his arbitrary appropriation of the Church's share of the tithes, in direct violation of the Vesterås Recess. Then Gustavus so curtailed the power of the bishops (ordinances of 1539 and 1540) that they had little of the dignity left but the name, and even that he was disposed to abolish, for after 1543 the prelates appointed by him, without any pretence of previous election by the cathedral chapters, were called ordinaries, or superintendents. Finally, at the Riksdag of Vesterås, in 1544, though no definite confession of faith was formulated, a final breach was made with the traditions of the old religion.

Breach with Rome.

Progress of the Reformation.

Recess and Ordinance of Vesteras, 1527.

Thus the Reformation in Sweden was practically the work of one strong man, acting (first from purely political and latterly from purely economical reasons) for the good of the state as he understood it. In this Gustavus acted contrary to the religious instincts of the vast majority of the Swedish nation; for there can be no doubt at all that the Swedes at the beginning of the 16th century were not only still devoted to the old Church, but violently anti-Protestant. This popular Romanism was the greatest of all Gustavus's difficulties, because it tended to alienate the Swedish peasants.

The Peasants.

For the last hundred years the peasants had been a leading factor in the political life of the land; and perhaps in no other contemporary European state could so self-reliant a class of yeomen have been found. Again and again they had defended their own and the national liberties against foreign foes. In the national assemblies, too, their voice had always been powerful, and not infrequently predominant. In a word, they were the sound kernel of the still but partially developed Swedish constitution, the democratic safeguard against the monarchical tendency which was enveloping the rest of Europe. Gustavus's necessities had compelled him to break with the ecclesiastical traditions of Sweden; and they also compelled him, contrary to his masterful disposition, to accept constitutionalism, because without it his footing in his own kingdom would have been insecure. The peasants therefore were his natural allies, but, from the nature of the case, they tended to become his most formidable rivals. They prided themselves on having "set King Gus in the high seat," but they were quite ready to unseat him if his rule was not to their liking, and there were many things with which they were by no means contented. This anomalous state of things was responsible for the half-dozen peasant risings with which Gustavus had to contend from 1525 to 1543. In all these rebellions the religious difficulty figured largely, though the increasing fiscal burdens were undoubtedly grievous and the peasants had their particular grievances besides. The wholesale seizure and degradation of Church property outraged them, and they formally protested against the introduction of "Luthery." They threatened, more than once, to march upon and destroy Stockholm, because the Reformers had made of it "a spiritual Sodom." They insisted on the restoration of the ancient Catholic customs, and would have made neglect of fasting and other sins of omission penal offences. Though he prevailed in the end, Gustavus was obliged to humour the people throughout. And thus, though he was strong enough to maintain what he had established and finish what he had begun, he was not strong enough to tamper seriously with the national liberties or to crush altogether Catholic aspirations. At the time of his death the Riksdag was already a power in the state, and a Catholic reaction in Sweden was by no means an impossibility, if only the Catholics had been able to find capable leaders.

Foreign Policy of Gustavus.

Gustavus's foreign policy at first aimed at little more than self-preservation. Only with the pecuniary assistance of the wealthy merchants of Lübeck had he been able to establish himself originally; and Lübeck, in return, had exploited Sweden, as Spain at a later day was to exploit her American colonies. When, with the aid of Denmark, Gustavus at last freed himself from this greedy incubus (see DENMARK; GUSTAVUS I.; CHRISTIAN III.) by the truce of the 28th of August 1537, Sweden for the first time in her history became the mistress of her own waters. But even so she was but of subordinate importance in Scandinavian politics. The hegemony of Denmark was indisputable, and Gustavus regarded that power with an ever-increasing suspicion which augured ill for peace in the future. The chief cause of dispute was the quartering by the Danish king of the three crowns of Sweden on the Dano-Norwegian shield, which was supposed to indicate a claim of sovereignty. Still more offensive was the attitude of Sweden's eastern neighbour Muscovy, with whom the Swedish king was nervously anxious to stand on good terms. Gustavus attributed to Ivan IV., whose resources he unduly magnified, the design of establishing a universal monarchy round the Baltic.

Expansion of Sweden.

Nevertheless events were already occurring which ultimately compelled Sweden to depart from her neutrality and lay the foundations of an overseas empire. In the last year of Gustavus's life (1560), the ancient military order of the Sword, amalgamated, since 1237, with the more powerful order of the Teutonic Knights, had by the secularization of the latter order into the dukedom of Prussia (1525) become suddenly isolated in the midst of hostile Slavonians. It needed but a jolt to bring down the crazy anachronism, and the jolt came when, in 1558–60, floods of Muscovites poured over the land, threatening the whole province with destruction. In his despair the last master of the order, Gotthard von Kettler, appealed to all his more civilized neighbours to save him, and his dominions were quickly partitioned between Poland, Denmark and Sweden. Sweden's original share of the spoil was Reval, which, driven to extremities, placed itself beneath the protection of the Swedish crown in March 1561. From the moment that Sweden got a firm footing in Esthonia by the acquisition of Reval she was committed to a policy of combat and aggrandisement. To have retreated would have meant the ruin of her Baltic trade, upon which the national prosperity so much depended. Her next-door neighbours, Poland and Russia, were necessarily her competitors; fortunately they were also each other's rivals; obviously her best policy was to counterpoise them. To accomplish this effectually she required to have her hands free, and the composition of her long-outstanding differences with Denmark by the Treaty of Stettin on the 13th of December 1570 (see DENMARK: *History*), which put an end to the Dano-Swedish war of 1563–1570, the chief political event of the reign of Eric XIV. (1560–1568), the eldest son and successor of Gustavus Vasa, was therefore a judicious act on the part of the new king of Sweden, John III. (1568–1592). Equally judicious was the anti-Russian league with Stephen Bathory, king of Poland, concluded in 1578. The war between Russia and Sweden for the possession of Esthonia and Livonia (1571–77) had been uninterruptedly disastrous to the latter, and, in the beginning of 1577, a countless Russian host sat down before Reval, Sweden's last stronghold in those parts. The energetic intervention of Bathory, however, speedily turned the scales in the opposite direction. Six months after his humiliating peace with the Polish monarch, Ivan IV. was glad to conclude a truce with Sweden also on a *uti possidetis* basis at Pliusa (Aug. 5, 1582).

Sweden and Poland.

The amicable relations between Sweden and Poland promised, at first, to be permanent. Sixteen years before his accession to the throne, John III., then duke of Finland, had wedded Catherine Jagiellonica, the sister of Sigismund II., king of Poland (Oct. 4, 1562). Duke Sigismund, the fruit of this union, was brought up by his mother in the Catholic religion, and, on the 19th of August 1587, he was elected king of Poland. Sixteen days later the Articles of Kalmar, signed by John and Sigismund, regulated the future relations between the two countries when, in process of time, Sigismund should succeed his father as king of Sweden. The two kingdoms were to be in perpetual alliance, but each of them was to retain its own laws and customs. Sweden was also to enjoy her religion, subject to such changes as a general council might make; but neither pope nor council was to claim or exercise the right of releasing Sigismund from his obligations to his Swedish subjects. During Sigismund's absence from Sweden that realm was to be ruled by seven Swedes, six elected by the king and one by his uncle Duke Charles of Sudermania, the leader of the Swedish Protestants. No new tax was to be levied in Sweden during the king's absence, but Sweden was never to be administered from Poland. Any necessary alterations in these articles were only to be made with the common consent of the king, Duke Charles, the senate and the gentry of Sweden.

Articles of Kalmar, 1587.

Sweden and the Catholic Reaction.

The endeavours of Swedish statesmen to bind the hands of their future king were due to their fear of the rising flood of the Catholic reaction in Europe. Under Eric XIV. the Reformation in Sweden had proceeded on much the same lines as during the reign of his father, retaining all the old Catholic customs not considered contrary to Scripture. Naturally, after 1544, when the Council of Trent had formally declared the Bible *and* tradition to be equally authoritative sources of all Christian doctrine, the contrast between the old and the new teaching became more obvious; and in many countries a middle party arose which aimed at a compromise by going back to the Church of the Fathers. King John III., the most learned of the Vasas, and somewhat of a theological expert, was largely influenced by these "middle" views. As soon as he had mounted the throne he took measures to bring the Swedish Church back to "the primitive Apostolic Church and the Catholic faith"; and, in 1574, persuaded a synod assembled at Stockholm to adopt certain articles framed by himself on what we should call a High Church basis. In February 1575 a new Church ordinance, approximating still more closely to the patristic Church, was presented to another synod, and accepted thereat, but very unwillingly. In 1576 a new liturgy was issued on the model of the Roman missal, but with considerable modifications. To a modern High Anglican these innovations seem innocent enough, and, despite the opposition of Duke Charles and the ultra-Protestants, they were adopted by the Riksdag of 1577. These measures greatly encouraged the Catholic party in Europe, and John III. was ultimately persuaded to send an embassy to Rome to open negotiations for the reunion of the Swedish Church with the Holy See. But though the Jesuit Antonio Possevino was sent to Stockholm to complete John's "conversion," John would only consent to embrace Catholicism under certain conditions which were never kept, and the only result of all these subterraneous negotiations was to incense the Protestants still more against the new liturgy, the use of which by every congregation in the realm without exception was, nevertheless, decreed by the Riksdag of 1582. At this period Duke Charles and his Protestant friends were clearly outnumbered by the promoters of the *via media*. Nevertheless, immediately after King John's death, a synod summoned to Upsala by Duke Charles rejected the new liturgy and drew up an anti-Catholic confession of faith (March 5, 1593). Holy Scripture and the three primitive creeds were declared to be the true foundations of Christian faith, and the Augsburg Confession was adopted. That Sigismund, now the lawful king of Sweden, should regard the summoning of the synod of Upsala without his previous knowledge and consent as a direct infringement of his prerogative was only natural. On his arrival in Sweden, however, he tried to gain time by provisionally confirming what had been done; but the aggressiveness of the Protestant faction and the persistent usurpations of Duke Charles (the Riksdag of 1595 proclaimed him regent though the king had previously refused him that office) made a civil war inevitable. The battle of Stångåbro (Sept. 25, 1598) decided the struggle in favour of Charles—and Protestantism. Sigismund fled from Sweden, never to return, and on the 19th of March 1600 the Riksdag of Linköping proclaimed the duke king under the title of Charles IX. Sigismund and his posterity were declared to have forfeited the Swedish crown which was to pass to the heirs male of Charles. Not till the 6th of March 1604, however, after Duke John, son of John III., had formally renounced his hereditary right to the throne, did Charles IX. begin to style himself king. At the Riksdag of the same year, the estates committed themselves irrevocably to Protestantism by excluding Catholics from the succession to the throne, and prohibiting them from holding any office or dignity in Sweden. Henceforth, too, every recusant was to be deprived of his estates and banished the realm.

John III. and the Swedish Church.

Civil War. Expulsion of Sigismund.

Proclamation of Charles IX., 1600.

Proscription of Catholics.

Establishment of a Regular Army.

It was in the reign of Charles IX. that Sweden became not only a predominantly Protestant, but also a predominantly military monarchy. This momentous change, which was to give a martial colouring to the whole policy of Sweden for the next hundred and twenty years, dates from a decree of the Riksdag of Linköping establishing, at the urgent suggestion of Charles, a regular army; each district in the country being henceforward liable to provide and maintain a fixed number of infantry and cavalry for the service of the state. The immediate enemy was Poland, now dynastically as well as territorially opposed to Sweden. The struggle took the shape of a contest for the possession of the northern Baltic provinces. Esthonia was recovered by the Swedes in 1600, but their

War with Poland and Russia.

determined efforts (1601–9) to gain a foothold in Livonia were frustrated by the military ability of the grand hetman of Lithuania, Jon Karol Chodkiewicz. In 1608 hostilities were transferred to Russian territory. At the beginning of that year Charles had concluded an alliance with Tsar Basil IV. (*q.v.*) against their common foe, the Polish king; but when, in 1611, Basil was deposed by his own subjects and the whole tsardom seemed to be on the verge of dissolution, Sweden's policy towards Russia changed its character. Hitherto Charles had aimed at supporting the weaker Slavonic power against the stronger; but now that Muscovy seemed about to disappear from among the nations of Europe, Swedish statesmen naturally sought some compensation for the expenses of the war before Poland had had time to absorb everything. A beginning was made by the siege and capture of Kexholm in Russian Finland (March 2, 1611); and, on the 16th of July, Great Novgorod was occupied and a convention concluded with the magistrates of that wealthy city whereby Charles IX.'s second son Philip was to be recognized as tsar, unless, in the meantime, relief came to Great Novgorod from Moscow. But now, when everything depended on a concentration of forces, Charles's imprudent assumption of the title of "King of the Lapps of Nordland," which people properly belonged to the Danish Crown, involved him in another war with Denmark, a war known in Scandinavian history as the war of Kalmar because the Swedish fortress of Kalmar was the chief theatre of hostilities. Thus the Swedish forces were diverted from their real objective and transferred to another field where even victory would have been comparatively unprofitable. But it was disaster, not victory, which Charles IX. reaped from this foolhardy enterprise. Still worse, the war of Kalmar, prudently concluded by Charles's son, Gustavus Adolphus, in the second year of his reign, by the peace of Knäred (Jan. 20, 1613) imposed such onerous pecuniary obligations and such intense suffering upon Sweden as to enkindle into a fire of hatred, which was to burn fiercely for the next two centuries, the long smouldering antagonism between the two sister nations of Scandinavia which dated back to the bloody days of Christian II.

War of Kalmar.

Peace of Knäred, 1613.

The Russian difficulty was more easily and more honourably adjusted. When Great Novgorod submitted provisionally to the suzerainty of Sweden, Swedish statesmen had believed, for a moment, in the creation of a Transbaltic dominion extending from Lake Ilmen northwards to Archangel and eastwards to Vologda. The rallying of the Russian nation round the throne of the new tsar, Michael Romanov, dissipated, once for all, this ambitious dream. By the beginning of 1616, Gustavus had become convinced of the impossibility of partitioning reunited Muscovy, while Muscovy recognized the necessity of buying off the invincible Swedes by some cession of territory. By the Peace of Stolbova (Feb. 27, 1617), the tsar surrendered to the Swedish king the provinces of Kexholm and Ingria, including the fortress of Nöteborg (the modern Schlüsselburg), the key of Finland. Russia, furthermore, renounced all claims upon Esthonia and Livonia, and paid a war indemnity of 20,000 roubles. In return for these concessions, Gustavus restored Great Novgorod and acknowledged Michael Romanov as tsar of Muscovy.

Peace of Stolbova, 1617.

The same period which saw the extension of the Swedish Empire abroad, saw also the peaceful development of the Swedish constitution at home. In this, as in every other matter, Gustavus himself took the initiative. Nominally the Senate still remained the dominant power in the state; but gradually all real authority had been transferred to the crown. The Riksråd speedily lost its ancient character of a grand council representing the semi-feudal landed aristocracy, and became a bureaucracy holding the chief offices of state at the good pleasure of the king. The Riksdag also changed its character at the same time. Whilst in every other European country except England, the ancient popular representation by estates was about to disappear altogether, in Sweden under Gustavus Adolphus it grew into an integral portion of the constitution. The Riksdag ordinance of 1617 first converted a turbulent and haphazard mob of "riksdagmen," huddling together like a flock of sheep "or drunken boors," into a dignified national assembly, meeting and deliberating according to rule and order. One of the nobility (first called the *Landtmarskalk*), or marshal of the Diet, in the Riksdag ordinance of 1526) was now regularly appointed by the king as the spokesman of the *Riddarhus*, or House of Nobles, while the primate generally acted as the *talman* or president of the three lower estates, the clergy, burgesses and peasants, though at a later day each of the three lower estates elected its own *talman*. At the opening of every session, the king submitted to the estates "royal propositions," or bills, upon which each estate proceeded to deliberate in its own separate chamber. The replies of the estates were delivered to the king at a subsequent session in congress. Whenever the estates differed amongst themselves, the king chose whatever opinion seemed best to him. The rights of the Riksdag were secured by the *Konungaförsäkran*, or assurance given by every Swedish king on his accession, guaranteeing the collaboration of the estates in the work of legislation, and they were also to be consulted on all questions of foreign policy. The king possessed the initiative; but the estates had the right of objecting to the measures of the government at the close of each session. It is in Gustavus's reign, too, that we first hear of the *Hemliga Utskott*, or "secret committee" for the transaction of extraordinary affairs, which was elected by the estates themselves. The eleven Riksdags held by Gustavus Adolphus were almost exclusively occupied in finding ways and means for supporting the ever-increasing burdens of the Polish and German wars. And to the honour of the Swedish people be it said that, from first to last, they showed a religious and patriotic zeal which shrank from no sacrifice. It was to this national devotion quite as much as to his own qualities that Gustavus owed his success as an empire-builder.

Rule of Gustavus Adolphus.

Constitutional Changes.

The wars with Denmark and Russia had been almost exclusively Scandinavian wars; the Polish war was of world-wide significance. It was, in the first place, a struggle for the Baltic littoral, and the struggle was intensified by the knowledge that the Polish Vasas denied the right of Gustavus to the Swedish throne. In the eyes of the Swedish king, moreover, the Polish War was a war of religion. Gustavus regarded the Scandinavian kingdoms as the two chief pillars on which the Evangelical religion reposed. Their disunion, he argued, would open a door in the north to the Catholic league and so bring about the destruction of Denmark and Sweden alike. Hence his alliance with Denmark to defend Stralsund in 1628. There is much of unconscious exaggeration in all this. As a matter of fact the Polish republic was no danger whatever to Protestantism. Sigismund's obstinate insistence upon his right to the Swedish crown was the one impediment to the conclusion of a war which the Polish Diet heartily detested and very successfully impeded. Apart from the semi-impotent Polish court, no responsible Pole dreamed of aggrandisement in Sweden. In fact, during the subsequent reign of Wladislaus IV. (1632–1648), the Poles prevented that martial monarch from interfering in the Thirty Years' War on the Catholic side. Gustavus, whose lively imagination was easily excited by religious ardour, enormously magnified clerical influence in Poland and frequently scented dangers where only difficulties existed.

War with Poland.

For eight years (1621–29) the exhausting and expensive Polish war dragged on. By the beginning of 1626 Livonia was conquered and the theatre of hostilities was transferred to the Prussian provinces of Poland (see Gustavus II. Adolphus; Koniecpolski [Stanislaus]). The fertile and easily defensible delta of the Vistula was now occupied and Gustavus treated it as a permanent conquest, making his great minister Axel Oxenstjerna its first governor-general. But this was the limit of the Swedish advance. All Gustavus's further efforts were frustrated by the superior strategy of the Polish grandhetman Koniecpolski, and, in June 1629, the king gladly accepted the lucrative truce of Altmark. By this truce Sweden was, for six years, to retain possession of her Livonian conquests, besides holding Elbing, the Vistula delta, Braunsberg in West, and Pillau and Memel in East Prussia, with the right to levy tolls at Pillau, Memel, Danzig, Labiau and Windau. From these tolls Gustavus derived, in 1629 alone, 500,000 rix-dollars, a sum equivalent to the whole of the extraordinary subsidies granted to him by the Riksdag. Thus Sweden held, for a time, the control of the principal trade routes of the Baltic up to the very confines of the empire; and the increment of revenue resulting from this commanding position was of material assistance to her during the earlier stages of the war in Germany, whither Gustavus transferred his forces in June 1630.

Sweden and the Thirty Years' War.

The motives of Gustavus in plunging into the Thirty Years' War and the details of the struggle as regards Sweden are elsewhere set forth (see GUSTAVUS II.; OXENSTJERNA [AXEL]; BANÉR [JOHAN]; TORSTENSSON [LENNART]). Here the only point to be insisted upon is the extreme precariousness of the Swedish position from first to last—a precariousness due entirely to inadequacy of material resources. In 1632 all Germany lay at the feet of Sweden; two years later a single disaster (Nördlingen) brought her empire to the verge of ruin. For the next seven years the German War as regards Sweden was a struggle for existence. She triumphed in the end, it is true, but it was a triumph due entirely to a lucky accident—the possession, during the crisis, of the greatest statesman and the greatest captain of the age. It was the exploits of Oxenstjerna and Banér which alone enabled Sweden to obtain even what she did obtain at the great Westphalian peace congress in 1648. Her original demands were Silesia (she held most of the fortresses there), Pomerania (which had been in her possession for nearly twenty years), and a war indemnity of 20,000,000 rix-dollars. What she actually got was (1) Upper Pomerania, with the islands of Rügen and Usedom, and a strip of Lower Pomerania on the right side of the Oder, including the towns of Stettin, Garz, Damm and Gollnow, and the isle of Wollin, with the right of succession to the rest of Lower Pomerania in the case of the extinction of the Brandenburg Hohenzollerns; (2) the town of Wismar with the districts of Poel and Neukloster; (3) the secularized bishoprics of Bremen and Verden; and (4) 5,000,000 rix-dollars. These German possessions were to be held as fiefs of the empire; and in respect thereof Sweden was to have a vote in the imperial Diet and to "direct" the Lower Saxon Circle alternately with Brandenburg. France and Sweden, moreover, became joint guarantors of the treaty with the emperor, and were entrusted with the carrying out of its provisions, which was practically effected by the executive congress of Nüremberg in 1650.

International Position of Sweden.

Sweden's reward for the exertions and sacrifices of eighteen years was meagre, almost paltry. Her newly won possessions were both small and scattered, though, on the other hand, she had secured the practical control of the three principal rivers of north Germany—the Oder, the Elbe and the Weser—and reaped the full advantage of the tolls levied on those great commercial arteries. The jealousy of France and the impatience of Queen Christina were the chief causes of the inadequacy of her final recompense. Yet, though the immediate gain was small, she had not dissipated her blood and treasure altogether in vain. Her vigorous intervention had saved the cause of religious liberty in Europe; and this remains, for all time, her greatest political achievement. Henceforth till her collapse, seventy years later, she was the recognized leader of Continental Protestantism. A more questionable benefit was her rapid elevation to the rank of an imperial power, an elevation which imposed the duty of remaining a military monarchy, armed *cap-à-pie* for every possible emergency. Every one recognizes now that the poverty and sparse population of Sweden unfitted her for such a tremendous destiny. But in the middle of the 17th century the incompatibility between her powers and her pretensions was not so obvious. All her neighbours were either decadent or exhausted states; and France, the most powerful of the Western powers, was her firm ally.

Queen Christina, 1644-1654.

For the moment, however, Sweden held the field. Everything depended upon the policy of the next few years. Very careful statesmanship might mean permanent dominion on the Baltic shore, but there was not much margin for blundering. Unfortunately the extravagance of Gustavus Adolphus's two immediate successors, Christina[1] and Charles X., shook the flimsy fabric of his empire to its very base. Christina's extravagance was financial. At the time of her abdication the state was on the verge of bankruptcy, and the financial difficulty had superinduced a serious political agitation. The mass of the Swedish people was penetrated by a justifiable fear that the external, artificial greatness of their country might, in the long run, be purchased with the loss of their civil and political liberties. In a word, the natural equilibrium of Swedish society was seriously threatened by the preponderance of the nobility; and the people at large looked to the new king to redress the balance. A better arbiter between the various estates than Charles X. it would have been difficult to find. It is true that, primarily a soldier, his whole ambition was directed towards military glory; but he was also an unusually sharp-sighted politician. He affected to believe that only by force of arms could Sweden retain the dominion which by force of arms she had won; but he also grasped the fact that there must be no disunion at home if she were to continue powerful abroad. The most pressing question of the day, the so-called *Reduktion*, or restitution of the alienated crown lands, was adjusted provisionally at the Riksdag of 1655. The king proposed that the actual noble holders of crown property should either pay an annual sum of 200,000 rix-dollars, to be allowed for out of any further crown lands subsequently falling in to them, or should surrender a fourth of the expectant property itself to the estimated amount of 600,000 rix-dollars. The nobility attempted to escape taxation as cheaply as possible by stipulating that the 6th of November 1632, the day of Gustavus Adolphus's death, should be the extreme limit of any restrospective action on the part of the crown in regard to alienated crown property, and that the present subsidy should be regarded as "a perpetual ordinance" unalterably to be observed by all future sovereigns—in other words, that there should be no further restitution of alienated crown property. Against this interpretation of the subsidy bill the already over-taxed lower estates protested so energetically that the Diet had to be suspended. Then the king intervened personally; not to quell the commons, as the senate insisted, but to compel the nobility to give way. He proposed that the whole matter should be thoroughly investigated by a special committee before the meeting of the next Riksdag, and that in the meantime a contribution should be levied on all classes proportionately. This equitable arrangement was accepted by the estates forthwith.

Charles X., 1654-1660.

Charles X.'s Wars.

Charles X. had done his best to obviate the effects of the financial extravagance of Christina. It may well be doubted, however, whether his own extravagant desire for military glory was not equally injurious to his country. In three days he had succeeded in persuading the Swedish estates of the lucrative expediency of his unnecessary and immoral attack on Poland (see POLAND: *History*); but when he quitted Stockholm for Warsaw, on the 10th of July 1654, he little imagined that he had embarked on an adventure which was to contribute far more to his glory than to the advantage of his country. How the Polish War expanded into a general European war; how Charles's miraculous audacity again and again ravished favours from Fortune and Nature (*e.g.* the passage of the Belts) when both those great powers combined against him; how, finally, he emerged from all his difficulties triumphant, indeed, but only to die of sheer exhaustion

[1] Christina's reign dates, properly, from 1644 when she attained her majority. From 1632 to 1644 Axel Oxenstjerna was virtually the ruler of Sweden.

in his thirty-eighth year—all this has elsewhere been described (see Charles X., king of Sweden; Czarniecki [Stephen]; Frederick III., king of Denmark). Suffice it to say that, immediately after his death, the regency appointed to govern Sweden during the minority of his only son and successor, Charles XI., a child four years old, hastened to come to terms with Sweden's numerous enemies, which now included Russia, Poland, Brandenburg and Denmark.

Charles XI.

Peace of Oliva, 1660.

The Peace of Oliva (May 3, 1660), made under French mediation, put an end to the long feud with Poland and, at the same time, ended the quarrel between Sweden on the one side, and the emperor and the elector of Brandenburg on the other. By this peace, Sweden's possession of Livonia, and the elector of Brandenburg's sovereignty over east Prussia, were alike confirmed; and the king of Poland renounced all claim to the Swedish crown. As regards Denmark, the Peace of Oliva signified the desertion of her three principal allies, Poland, Brandenburg and the emperor, and thus compelled her to reopen negotiations with Sweden direct. The differences between the two states were finally adjusted by the peace of Copenhagen (May 27, 1660), Denmark ceding the three Scanian provinces to Sweden but receiving back the Norwegian province of Trondhjem and the isle of Bornholm which she had surrendered by the peace of Roskilde two years previously. Denmark was also compelled to recognize, practically, the independence of the dukes of Holstein-Gottorp. The Russian War was terminated by the Peace of Kardis (July 2, 1661), confirmatory of the Peace of Stolbova, whereby the tsar surrendered to Sweden all his Baltic provinces—Ingria, Esthonia and Kexholm.

Sweden as a Great Power.

Thus Sweden emerged from the war not only a military power of the first magnitude, but also one of the largest states of Europe, possessing about twice as much territory as modern Sweden. Her area embraced 16,800 geographical square miles, a mass of land 7000 sq. m. larger than the modern German Empire. Yet the Swedish Empire was rather a geographical expression than a state with natural and national boundaries. Modern Sweden is bounded by the Baltic; during the 17th century the Baltic was merely the bond between her various widely dispersed dominions. All the islands in the Baltic, except the Danish group, belonged to Sweden. The estuaries of all the great German rivers (for the Niemen and Vistula are properly Polish rivers) debouched in Swedish territory, within which also lay two-thirds of Lake Ladoga and one-half of Lake Peipus. Stockholm, the capital, lay in the very centre of the empire, whose second greatest city was Riga, on the other side of the sea. Yet this vast empire contained but half the population of modern Sweden—being only 2,500,000, or about 140 souls to the square mile. Further, Sweden's new boundaries were of the most insecure description, inasmuch as they were anti-ethnographical, parting asunder races which naturally went together, and behind which stood powerful neighbours of the same stock ready, at the first opportunity, to reunite them.

Moreover, the commanding political influence which Sweden had now won was considerably neutralized by her loss of moral prestige. On Charles X.'s accession in 1655, Sweden's neighbours, though suspicious and uneasy, were at least not adversaries, and might have been converted into allies of the new great power who, if she had mulcted them of territory, had, anyhow, compensated them for the loss with the by no means contemptible *douceur* of religious liberty. At Charles X.'s death, five years later, we find Sweden, herself bled to exhaustion point, surrounded by a broad belt of desolated territory and regarded with ineradicable hatred by every adjacent state. To sink in five years from the position of the champion of Protestantism to that of the common enemy of every Protestant power was a degradation not to be compensated by any amount of military glory. Charles's subsequent endeavour, in stress of circumstances, to gain a friend by dividing his Polish conquests with the aspiring elector of Brandenburg was a reversal of his original policy and only resulted in the establishment on the southern confines of Sweden of a new rival almost as dangerous as Denmark, her ancient rival in the west.

Minority of Charles XI.

In 1660, after five years of incessant warfare, Sweden had at length obtained peace and with it the opportunity of organizing and developing her newly won empire. Unfortunately, the regency which was to govern her during the next fifteen years was unequal to the difficulties of a situation which might have taxed the resources of the wisest statesmen. Unity and vigour were scarcely to be expected from a many-headed administration composed of men of mediocre talent whose contrary opinions speedily gave rise to contending factions. There was the high-aristocratic party with a leaning towards martial adventure headed by Magnus de la Gardie (*q.v.*), and the party of peace and economy whose ablest representative was the liberal and energetic Johan Gyllenstjerna (*q.v.*). After a severe struggle, de la Gardie's party prevailed; and its triumph was marked by that general decline of personal and political morality which has given to this regency its unenviable notoriety. Sloth and carelessness speedily invaded every branch of the administration, destroying all discipline and leading to a general neglect of business. Another characteristic of the de la Gardie government was its gross corruption, which made Sweden the obsequious hireling of that foreign power which had the longest purse. This shameful "subsidy policy" dates from the Treaty of Fontainebleau, 1661, by a secret paragraph of which Sweden, in exchange for a considerable sum of money, undertook to support the French candidate on the first vacancy of the Polish throne. The complications ensuing from Louis XIV.'s designs on the Spanish Netherlands led to a bid for the Swedish alliance, both from the French king and his adversaries. After much hesitation on the part of the Swedish government, the anti-French faction prevailed; and in April 1668 Sweden acceded to the Triple Alliance, which finally checkmated the French king by bringing about the Peace of Aix-la-Chapelle. For the next four years Sweden remained true to the principles of the Triple Alliance; but, in 1672, Louis XIV. succeeded in isolating the Dutch republic and regaining his ancient ally, Sweden. By the Treaty of Stockholm (April 14, 1672), Sweden became, for the next ten years, a "mercenarius Galliae," pledging herself, in return for 400,000 crowns per annum in peace and 600,000 in war-time, to attack, with 16,000 men, any German princes who might be disposed to assist Holland. In 1674 Louis XIV. peremptorily called upon Sweden to fulfil her obligations by invading Brandenburg. In the course of May 1675 a Swedish army advanced into the Mark, but on the 18th of June was defeated at Fehrbellin, and hastily retreated to Demmin. The Fehrbellin affair was a mere skirmish, the actual casualties amounting to less than 600 men, but it rudely divested Sweden of her nimbus of invincibility and was the signal for a general attack upon her, known as the Scanian War.

Alliance with France.

The Scanian War.

In the course of the next three years her empire seemed to be crumbling away everywhere. In 1675 Pomerania and the bishopric of Bremen were overrun by the Brandenburgers, Austrians and Danes. In December 1677 the elector of Brandenburg captured Stettin. Stralsund fell on the 15th of October 1678. Greifswald, Sweden's last possession on the Continent, was lost on the 5th of November. A defensive alliance with Sobieski (August 4, 1677) was rendered inoperative by the annihilation of Sweden's sea-power (battle of Öland, June 17, 1676; battle of Fehmarn, June 1677) and the difficulties of the Polish king.

Two accidents at this crisis alone saved Sweden from ruin—the splendid courage of the young king who, resolutely and successfully, kept the Danish invaders at bay (see Charles XI., king of Sweden), and the diplomatic activity of Louis XIV. In March 1677 a peace congress began its sessions at Nijmwegen; and in the beginning of April 1678 the French king dictated the terms of a general pacification. One of his chief conditions was the complete restitution of Sweden. A strong Sweden was necessary to the accomplishment of his plans. He suggested, however, that Sweden should rid herself of her enemies by making some "small cession" to them. This Charles XI. refused to do, whereupon Louis took it upon himself to conclude peace on Sweden's account without consulting the wishes of the Swedish king. By this Treaty of Nijmwegen (Feb. 7) and of St Germain (June 29, 1679) Sweden virtually received full restitution of her German territory. On the 2nd of September by the Peace of Fontainebleau (confirmed by the subsequent Peace of Lund, Oct. 4, 1679), Denmark was also forced to retrocede her conquests. It is certain that Sweden herself could never have extorted such favourable terms, yet "the insufferable tutelage" of France on this occasion inspired Charles XI. with a personal dislike of the mighty ruler of France and contributed to reverse the traditional diplomacy of Sweden by giving it a strong anti-French bias (see CHARLES XI.; OXENSTJERNA, BENEDICT).

Treaty of Nijmwegen, 1679.

The remainder of the reign of Charles XI. is remarkable for a revolution which converted the government of Sweden into a semi-absolute monarchy. The king emerged from the war convinced that if Sweden were to retain her position as a great power she must radically reform her whole economical system, and, above all, circumscribe the predominant and mischievous influence of an aristocracy which thought far more of its privileges than of its public duties. He felt that he could now draw upon the confidence and liberality of the lower orders to an unlimited extent, and he proceeded to do so. The Riksdag which assembled in Stockholm in October 1680 begins a new era of Swedish history. On the motion of the Estate of Peasants, which had a long memory for aristocratic abuses, the question of the recovery of the alienated crown lands was brought before the Riksdag, and, despite the stubborn opposition of the magnates, a resolution of the Diet directed that all countships, baronies, domains, manors and other estates producing an annual rent of more than £70 per annum should revert to the Crown. The same Riksdag decided that the king was not bound by any particular constitution, but only by law and the statutes. Nay, they added that he was not even obliged to consult the council of state, but was to be regarded as a sovereign lord, responsible to God alone for his actions, and requiring no intermediary between himself and his people. The council thereupon acquiesced in its own humiliation by meekly accepting a royal brief changing its official title from *Riksråd* (council of state) to *Kungligaråd* (royal council)—a visible sign that the senators were no longer the king's colleagues but his servants.

Charles XI. and the Swedish Constitution.

Thus Sweden, as well as Denmark, had become an absolute monarchy, but with this important difference, that the right of the Swedish people, in parliament assembled, to be consulted on all important matters was recognized and acted upon. The Riksdag, completely overshadowed by the throne, was during the reign of Charles XI. to do little more than register the royal decrees; but nevertheless it continued to exist as an essential part of the machinery of government. Moreover, this transfer of authority was a voluntary act. The people, knowing the king to be their best friend, trusted him implicitly and cooperated with him cheerfully. The Riksdag of 1682 proposed a fresh Reduktion, and declared that the whole question of how far the king was empowered by the law of the land to bestow fiefs, or, in case of urgent national distress, take them back again, was exclusively his majesty's affair. In other words, it made the king the disposer of his subjects' temporal property. Presently this new principle of autocracy was extended to the king's legislative authority also, for, on the 9th of December 1682, all four estates, by virtue of a common declaration, not only confirmed him in the possession of the legislative powers enjoyed by his predecessors, but even conceded to him the right of interpreting and amending the common law.

The recovery of the alienated crown lands occupied Charles XI. for the rest of his life. It was conducted by a commission which was ultimately converted into a permanent department of state. It acted on the principle that the titles of all private landed estate might be called in question, inasmuch as at some time or other it must have belonged to the Crown; and the burden of proof of ownership was held not to lie with the Crown which made the claim, but with the actual owner of the property. The amount of revenue accruing to the Crown from the whole Reduktion it is impossible to estimate even approximately; but by these means, combined with the most careful management and the most rigid economy, Charles XI. contrived to reduce the national debt from £2,567,000 to £700,000.

These operations represent only a part of Charles XI.'s gigantic activity. Here we have only space sufficient to glance at his reorganization of the national armaments. Charles XI. re-established on a broader basis the *indelningsverk* introduced by Charles IX.—a system of military tenure whereby the national forces were bound to the soil. Thus there was the *rusthåll* tenure, under which the tenants, instead of paying rent, were obliged to equip and maintain a cavalry soldier and horse, while the *knekthållarer* supplied duly equipped foot soldiers. These *indelning* soldiers were provided with holdings on which they lived in times of peace. Formerly, ordinary conscription had existed alongside this *indelning*, or distribution system; but it had proved inadequate as well as highly unpopular; and, in 1682, Charles XI. came to an agreement with the peasantry whereby an extended *indelning* system was to be susbstituted for general conscription. The navy, of even more importance to Sweden if she were to maintain the dominion of the Baltic, was entirely remodelled; and, the recent war having demonstrated the unsuitability of Stockholm as a naval station, the construction of a new arsenal on a gigantic scale was simultaneously begun at Karlskrona. After a seventeen years' struggle against all manner of financial difficulties, the twofold enterprise was completed. At the death of Charles XI. Sweden could boast of a fleet of forty-three three-deckers (manned by 11,000 men and armed with 2648 guns) and one of the finest arsenals in the world.

Reorganization of Armaments.

Charles XI. had carefully provided against the contingency of his successor's minority; and the five regents appointed by him, if not great statesmen, were at least practical politicans who had not been trained in his austere school in vain. At home the Reduktion was cautiously pursued, while abroad the successful conclusion of the great peace congress at Ryswick was justly regarded as a signal triumph of Sweden's pacific diplomacy (see OXENSTJERNA FAMILY). The young king was full of promise, and had he been permitted gradually to gain experience and develop his naturally great talents beneath the guidance of his guardians, as his father had intended, all might have been well for Sweden. Unfortunately, the sudden, noiseless revolution of the 6th of November 1697, which made Charles XII. absolute master of his country's fate in his fifteenth year (see CHARLES XII.), and the league of Denmark, Saxony and Russia, formed two years later to partition Sweden (see PATKUL, JOHANN REINHOLD; PETER THE GREAT; CHARLES XII.), precipitated Sweden into a sea of troubles in which she was finally submerged.

Charles XII., 1697-1718.

From the very beginning of the Great Northern War Sweden suffered from the inability of Charles XII. to view the situation from anything but a purely personal point of view. His determination to avenge himself on enemies overpowered every other consideration. Again and again during these eighteen years of warfare it was in his power to dictate an advantageous peace. After the dissipation of the first coalition against him by the peace of Travendal (Aug. 18, 1700) and the victory of Narva (Nov. 20, 1700), the Swedish chancellor, Benedict Oxenstjerna, rightly regarded the universal bidding for the favour of Sweden by France and the maritime powers, then on the eve of the War of the Spanish Succession, as a golden opportunity of "ending this present lean war and making his majesty the arbiter of Europe." But Charles, intent on dethroning Augustus of Poland, held haughtily aloof. Subsequently in 1701 he rejected a personal appeal from William III. to conclude peace on his

Great Northern War.

own terms. Five years later (Sept. 24, 1706) he did, indeed, conclude the Polish War by the peace of Altranstädt, but as this treaty brought no advantage to Sweden, not even compensation for the expenses of six years of warfare, it was politically condemnable. Moreover, two of Sweden's Baltic provinces, Esthonia and Ingria, had been seized by the tsar, and a third, Livonia, had been well-nigh ruined. Yet even now Charles, by a stroke of the pen, could have recovered nearly everything he had lost. In 1707 Peter was ready to retrocede everything except St Petersburg and the line of the Neva, and again Charles preferred risking the whole to saving the greater part of his Baltic possessions (for details see CHARLES XII.; PETER THE GREAT). When at last, after the catastrophe of Poltava (June 1709) and the flight into Turkey, he condescended to use diplomatic methods, it was solely to prolong, not to terminate, the war. Even now he could have made honourable terms with his numerous enemies. The resources of Sweden were still very far from being exhausted, and, during 1710 and 1711, the gallant Magnus Stenbock (*q.v.*) upheld her military supremacy in the north. But all the efforts of the Swedish government were wrecked on the determination of Charles XII. to surrender nothing. Thus he rejected advantageous offers of mediation and alliance made to him, during 1712, by the maritime powers and by Prussia; and, in 1714, he scouted the friendly overtures of Louis XIV. and the emperor, so that when peace was finally concluded between France and the Empire, at the congress of Baden, Swedish affairs were, by common consent, left out of consideration. When, on the 14th of September 1714, he suddenly returned to his dominions, Stralsund and Wismar were all that remained to him of his continental possessions; while by the end of 1715 Sweden, now fast approaching the last stage of exhaustion, was at open war with England, Hanover, Russia, Prussia, Saxony and Denmark, who had formed a coalition to partition her continental territory between them. Nevertheless, at this the eleventh hour of her opportunities, Sweden might still have saved something from the wreck of her empire if Charles had behaved like a reasonable being (see CHARLES XII.; PETER THE GREAT; GÖRTZ, GEORG HEINRICH VON; OSTERMAN, ANDREI); but he would only consent to play off Russia against England, and his sudden death before Fredrikshald (Dec. 11, 1718) left Sweden practically at the end of her resources and at the mercy of her enemies. At the beginning of 1719 pacific overtures were made to England, Hanover, Prussia and Denmark. By the treaties of Stockholm (Feb. 20, 1719, and Feb. 1, 1720) Hanover obtained the bishoprics of Bremen and Verden for herself and Stettin for her confederate Prussia. By the treaty of Frederiksborg or Copenhagen (July 3, 1720) peace was also signed between Denmark and Sweden, Denmark retroceding Rügen, Further Pomerania as far as the Peene, and Wismar to Sweden, in exchange for an indemnity of 600,000 rix-dollars, while Sweden relinquished her exemption from the Sound tolls and her protectorate over Holstein-Gottorp. The prospect of coercing Russia by means of the British fleet had alone induced Sweden to consent to such sacrifices; but when the last demands of England and her allies had been complied with, Sweden was left to come to terms as best she could with the tsar. Negotiations were reopened with Russia at Nystad, in May 1720, but peace was not concluded till the 30th of August 1721, and then only under the direst pressure. By the peace of Nystad Sweden ceded to Russia Ingria and Esthonia, Livonia, the Finnish province of Kexholm and the fortress of Viborg. Finland west of Viborg and north of Kexholm was restored to Sweden. She also received an indemnity of two millions of thalers and a solemn undertaking of non-interference in her domestic affairs.

Treaties of Stockholm and Frederiksborg, 1719 and 1720.

Peace of Nystad, 1721. Loss of the Baltic Provinces.

It was not the least of Sweden's misfortunes after the Great Northern War that the new constitution, which was to compensate her for all her past sacrifices, should contain within it the elements of many of her future calamities. Early in 1720 Charles XII.'s sister, Ulrica Leonora, who had been elected queen of Sweden immediately after his death, was permitted to abdicate in favour of her husband the prince of Hesse, who was elected king under the title of Frederick I.; and Sweden was, at the same time, converted into the most limited of monarchies. All power was vested in the people as represented by the Riksdag, consisting, as before, of four distinct estates, nobles, priests, burgesses and peasants, sitting and deliberating apart. The conflicting interests and mutual jealousies of these four independent assemblies made the work of legislation exceptionally difficult. No measure could now become law till it had obtained the assent of three at least of the four estates; but this provision, which seems to have been designed to protect the lower orders against the nobility, produced evils far greater than those which it professed to cure. Thus, measures might be passed by a bare majority in three estates, when a real and substantial majority of all four estates in congress might be actually against it. Or, again, a dominant action in any three of the estates might enact laws highly detrimental to the interests of the remaining estate—a danger the more to be apprehended as in no other country in Europe were class distinctions so sharply defined as in Sweden.

Frederick I., 1720-1751. The Limited Monarchy.

Each estate was ruled by its *talman*, or speaker, who was now elected at the beginning of each Diet, but the archbishop was, *ex officio*, the *talman* of the clergy. The *landtmarskalk*, or speaker of the House of Nobles, presided when the estates met in congress, and also, by virtue of his office, in the *hemliga utskott*, or secret committee. This famous body, which consisted of 50 nobles, 25 priests, 25 burgesses, and, very exceptionally, 25 peasants, possessed during the session of the Riksdag not only the supreme executive but also the surpeme judicial and legislative functions. It prepared all bills for the Riksdag, created and deposed all ministries, controlled the foreign policy of the nation, and claimed and often exercised the right of superseding the ordinary courts of justice. During the parliamentary recess, however, the executive remained in the hands of the *rad*, or senate, which was responsible to the Riksdag alone.

Constitution of the Estates.

It will be obvious that there was no room in this republican constitution for a constitutional monarch in the modern sense of the word. The crowned puppet who possessed a casting vote in the *råd*, of which he was the nominal president, and who was allowed to create peers once in his life (at his coronation), was rather a state decoration than a sovereignty.

At first this cumbrous and complicated instrument of government worked tolerably well under the firm but cautious control of the chancellor, Count Arvid Beernhard Horn (*q.v.*). In his anxiety to avoid embroiling his country abroad, Horn reversed the traditional policy of Sweden by keeping France at a distance and drawing near to Great Britain, for whose liberal institutions he professed the highest admiration. Thus a twenty years' war was succeeded by a twenty years' peace, during which the nation recovered so rapidly from its wounds that it began to forget them. A new race of politicians was springing up. Since 1719, when the influence of the few great territorial families had been merged in a multitude of needy gentlemen, the first estate had become the nursery and afterwards the stronghold of an opposition at once noble and democratic which found its natural leaders in such men as Count Carl Gyllenborg and Count Carl Gustaf Tessin (*q.v.*). These men and their followers were never weary of ridiculing the timid caution of the aged statesman who sacrificed everything to perpetuate an inglorious peace and derisively nicknamed his adherents "Night-caps" (a term subsequently softened into "Caps"), themselves adopting the sobriquet "Hats," from the three-cornered hat worn by officers and gentlemen, which was considered happily to hit off the manly self-assertion of the opposition. These epithets instantly caught the public fancy and had already become party badges when the estates met in 1738. This Riksdag was to mark another turning-point in Swedish

Political Parties. Hats and Caps.

history. The Hats carried everything before them; and the aged Horn was finally compelled to retire from a scene where, for three and thirty years, he had played a leading part.

The policy of the Hats was a return to the traditional alliance between France and Sweden. When Sweden descended to her natural position as a second-rate power the French alliance became too costly a luxury. Horn had clearly perceived this; and his cautious neutrality was therefore the soundest statesmanship. But the politicians who had ousted Horn thought differently. To them prosperity without glory was a worthless possession. They aimed at restoring Sweden to her former position as a great power. France, naturally, hailed with satisfaction the rise of a faction which was content to be her armour-bearer in the north; and the golden streams which flowed from Versailles to Stockholm during the next two generations were the political life-blood of the Hat party.

French Alliance.

The first blunder of the Hats was the hasty and ill-advised war with Russia. The European complications consequent upon the almost simultaneous deaths of the emperor Charles VI. and Anne, empress of Russia, seemed to favour their adventurous schemes; and, despite the frantic protests of the Caps, a project for the invasion of Russian Finland was rushed through the premature Riksdag of 1740. On the 20th of July 1741 war was formally declared against Russia; a month later the Diet was dissolved and the Hat *landtmarskalk* set off to Finland to take command of the army. The first blow was not struck till six months after the declaration of war; and it was struck by the enemy, who routed the Swedes at Villmanstrand and captured that frontier fortress. Nothing else was done on either side for six months more; and then the Swedish generals made a "tacit truce" with the Russians through the mediation of the French ambassador at St Petersburg. By the time that the "tacit truce" had come to an end the Swedish forces were so demoralized that the mere rumour of a hostile attack made them retire panic-stricken to Helsingfors; and before the end of the year all Finland was in the hands of the Russians. The fleet, disabled by an epidemic, was, throughout the war, little more than a floating hospital.

War with Russia, 1741.

To face the Riksdag with such a war as this upon their consciences was a trial from which the Hats naturally shrank; but, to do them justice, they showed themselves better parliamentary than military strategists. A motion for an inquiry into the conduct of the war was skilfully evaded by obtaining precedence for the succession question (Queen Ulrica Leonora had lately died childless and King Frederick was old); and negotiations were thus opened with the new Russian empress, Elizabeth, who agreed to restore the greater part of Finland if her cousin, Adolphus Frederick of Holstein, were elected successor to the Swedish crown. The Hats eagerly caught at the opportunity of recovering the grand duchy and their own prestige along with it. By the peace of Åbo (May 7, 1743) the terms of the empress were accepted; and only that small part of Finland which lay beyond the Kymmene was retained by Russia.

Peace of Åbo, 1743.

In March 1751 old King Frederick died. His slender prerogatives had gradually dwindled down to vanishing point. Adolphus Frederick (*q.v.*) would have given even less trouble than his predecessor but for the ambitious promptings of his masterful consort Louisa Ulrica, Frederick the Great's sister, and the tyranny of the estates, who seemed bent upon driving the meekest of princes into rebellion. An attempted monarchical revolution, planned by the queen and a few devoted young nobles in 1756, was easily and remorselessly crushed; and, though the unhappy king did not, as he anticipated, share the fate of Charles Stuart, he was humiliated as never monarch was humiliated before.

Adolphus Frederick II., 1751-1771.

The same years which beheld this great domestic triumph of the Hats saw also the utter collapse of their foreign "system." At the instigation of France they plunged recklessly into the Seven Years' War; and the result was ruinous. The French subsidies, which might have sufficed for a six weeks' demonstration (it was generally assumed that the king of Prussia would give little trouble to a European coalition), proved quite inadequate; and, after five unsuccessful campaigns, the unhappy Hats were glad to make peace and ignominiously withdraw from a little war which had cost the country 40,000 men and £2,500,000. When the Riksdag met in 1760, the indignation against the Hat leaders was so violent that an impeachment seemed inevitable; but once more the superiority of their parliamentary tactics prevailed, and when, after a session of twenty months, the Riksdag was brought to a close by the mutual consent of both the exhausted factions, the Hat government was bolstered up for another four years. But the day of reckoning could not be postponed for ever; and when the estates met in 1765 it brought the Caps into power at last. Their leader, Ture Rudbeck, was elected marshal of the Diet over Frederick Axel von Fersen (*q.v.*), the Hat candidate, by a large majority; and, out of the hundred seats in the secret committee, the Hats succeeded in getting only ten.

The Seven Years' War.

The Caps struck at once at the weak point of their opponents by ordering a budget report to be made; and it was speedily found that the whole financial system of the Hats had been based upon reckless improvidence and wilful misrepresentation, and that the only fruit of their long rule was an enormous addition to the national debt and a depreciation of the note circulation to one-third of its face value. This revelation led to an all-round retrenchment, carried into effect with a drastic thoroughness which has earned for this parliament the name of the "Reduktion Riksdag." The Caps succeeded in transferring £250,000 from the pockets of the rich to the empty exchequer, reducing the national debt by £575,179, and establishing some sort of equilibrium between revenue and expenditure. They also introduced a few useful reforms, the most remarkable of which was the liberty of the press. But their most important political act was to throw their lot definitely in with Russia, so as to counterpoise the influence of France. Sweden was not then as now quite outside the European Concert. Alghough no longer a great power, she still had many of the responsibilities of a great power; and if the Swedish alliance had considerably depreciated in value, it was still a marketable commodity. Sweden's peculiar geographical position made her virtually invulnerable for six months out of the twelve, her Pomeranian possessions afforded her an easy ingress into the very heart of the moribund empire, while her Finnish frontier was not many leagues from the Russian capital.

Rule of the Caps.

Russian Alliance.

A watchful neutrality, not venturing much beyond defensive alliances and commercial treaties with the maritime powers, was therefore Sweden's safest policy, and this the older Caps had always followed out. But when the Hats became the armour-bearers of France in the north, a protector strong enough to counteract French influence became the cardinal exigency of their opponents, the younger Caps, who now flung themselves into the arms of Russia, overlooking the fact that even a pacific union with Russia was more to be feared than a martial alliance with France. For France was too distant to be dangerous. She sought an ally in Sweden and it was her endeavour to make that ally as strong as possible. But it was as a future prey, not as a possible ally, that Russia regarded her ancient rival in the north. In the treaty which partitioned Poland there was a secret clause which engaged the contracting powers to uphold the existing Swedish constitution as the swiftest means of subverting Swedish independence; and an alliance with the credulous Caps, "the Patriots" as they were called at St Petersburg, guaranteeing their constitution, was the corollary to this secret understanding. Thus, while the French alliance of the warlike Hats had destroyed the prestige of Sweden, the Russian alliance of the peaceful Caps threatened to destroy her very existence.

Fortunately, the domination of the Caps was not for long. The general distress occasioned by their drastic reforms had found expression in swarms of pamphlets which bit and stung the Cap government, under the protection of the new press laws. The senate retaliated by an order in council (which the king refused to sign) declaring that all complaints against the measures of the last Riksdag should be punished with fine and imprisonment. The king, at the suggestion of the crown prince (see GUSTAVUS III.), thereupon urged the senate to summon an extraordinary Riksdag as the speediest method of relieving the national distress, and, on their refusing to comply with his wishes, abdicated. From the 15th of December to the 21st of December 1768 Sweden was without a regular government. Then the Cap senate gave way and the estates were convoked for the 19th of April 1769.

On the eve of the contest there was a general assembly of the Hats at the French embassy, where the Comte de Modène furnished them with 6,000,000 livres, but not till they had signed in his presence an undertaking to reform the constitution in a monarchical sense. Still more energetic on the other side, the Russian minister, Ivan Osterman, became the treasurer as well as the counsellor of the Caps, and scattered the largesse of the Russian empress with a lavish hand; and so lost to all feeling of patriotism were the Caps that they openly threatened all who ventured to vote against them with the Muscovite vengeance, and fixed Norrköping, instead of Stockholm, as the place of meeting for the Riksdag as being more accessible to the Russian fleet. But it soon became evident that the Caps were playing a losing game; and, when the Riksdag met at Norrköping on the 19th of April, they found themselves in a minority in all four estates. In the contest for the marshalate of the Diet the leaders of the two parties were again pitted against each other, when the verdict of the last Riksdag was exactly reversed, Fersen defeating Rudbeck by 234, though Russia spent no less a sum than £11,500 to secure the election of the latter.

Defeat of the Caps.

The Caps had short shrift, and the joint note which the Russian, Prussian and Danish ministers presented to the estates protesting, in menacing terms, against any "reprisals" on the part of the triumphant faction, only hastened the fall of the government. The Cap senate resigned *en masse* to escape impeachment, and an exclusively Hat ministry took its place. On the 1st of June the Reaction Riksdag, as it was generally called, removed to the capital; and it was now that the French ambassador and the crown prince Gustavus called upon the new senators to redeem their promise as to a reform of the constitution which they had made before the elections. But when, at the fag-end of the session, they half-heartedly brought the matter forward, the Riksdag suddenly seemed to be stricken with paralysis. Impediments multiplied at every step; the cry was raised: "The constitution is in danger"; and on the 30th of January 1770 the Reaction Riksdag, after a barren ten months' session, rose amidst chaotic confusion without accomplishing anything.

The Reaction Riksdag.

Adolphus Frederick died on the 12th of February 1771. The elections held on the demise of the Crown resulted in a partial victory for the Caps, especially among the lower orders; but in the estate of the peasants their majority was merely nominal, while the mass of the nobility was dead against them. Nothing could be done, however, till the arrival of the new king (then at Paris), and every one felt that with Gustavus III. an entirely incalculable factor had entered into Swedish politics. Unknown to the party leaders, he had already renewed the Swedish alliance with France and had received solemn assurances of assistance from Louis XV. in case he succeeded in re-establishing monarchical rule in Sweden. France undertook, moreover, to pay the outstanding subsidies to Sweden, amounting to one and a half millions of livres annually, beginning from January 1772; and Vergennes, one of the great names of French diplomacy, was to be sent to circumvent the designs of Russia at Stockholm as he had previously circumvented them at Constantinople. Immediately after his return to Stockholm, Gustavus endeavoured to reconcile the jarring factions by inducing the leaders to form a composition committee to adjust their differences. In thus mediating he was sincere enough, but all his pacific efforts were frustrated by their jealousy of him and of each other. Still worse, the factions now intrenched still further on the prerogative. The new coronation oath contained three revolutionary clauses. The first aimed at making abdications in the future impossible by binding the king to reign uninterruptedly. The second obliged him to abide, not by the decision of all the estates together, as heretofore, but by that of the majority only, with the view of enabling the actually dominant lower estates (in which was a large Cap majority) to rule without, and even in spite of, the nobility. The third clause required him, in all cases of preferment, to be guided not "principally," as heretofore, but "solely" by merit, thus striking at the very root of aristocratic privilege. It was clear that the ancient strife of Hats and Caps had become merged in a conflict of classes; the situation was still further complicated by the ominous fact that the non-noble majority was also the Russian faction.

Gustavus III., 1771-1792.

All through 1771 the estates were wrangling over the clauses of the coronation oath. A second attempt of the king to mediate between them foundered on the suspicions of the estate of burgesses; and, on the 24th of February 1772, the nobility yielded from sheer weariness. The non-noble Cap majority now proceeded to attack the senate, the last stronghold of the Hats, and, on the 25th of April, succeeded in ousting their opponents. It was now, for the first time, that Gustavus, reduced to the condition of a *roi fainéant*, began seriously to consider the possibility of a revolution; of its necessity there could be no doubt. Under the sway of the now dominant faction, Sweden, already the vassal, could not fail speedily to become the victim of Russia. She was on the point of being absorbed in that Northern System, the invention of the Russian minister of foreign affairs, Nikita Panin (*q.v.*), which that patient statesman had made it the ambition of his life to realize. Only a swift and sudden *coup d'état* could save the independence of a country isolated from the rest of Europe by a hostile league. The details of the famous revolution of the 19th of August 1772 are elsewhere set forth (see GUSTAVUS III.; TOLL, JOHAN KRISTOFFER; SPRENGTPORTEN, JAKOB MAGNUS). Here we can only dwell upon its political importance and consequences. The new constitution of the 20th of August 1772, which Gustavus imposed upon the terrified estates at the bayonet's point, converted a weak and disunited republic into a strong but limited monarchy, in which the balance of power inclined, on the whole, to the side of the monarch. The estates could only assemble when summoned by him; he could dismiss them whenever he thought fit; and their deliberations were to be confined exclusively to the propositions which he might think fit to lay before them. But these very extensive powers were subjected to many important checks. Thus, without the previous consent of the estates, no new law could be imposed, no old law abolished, no offensive war undertaken, no extraordinary war subsidy levied. The estates alone could tax themselves; they had the absolute control of the Bank of Sweden, and the inalienable right of controlling the national expenditure. Thus the parliament held the purse; and this seemed a sufficient guarantee both of its independence and its frequent convention. The senate, not the Riksdag, was the chief loser by the change; and, inasmuch as henceforth the senators were appointed by the king, and were to be responsible to him alone, a senate in opposition to the Crown was barely conceivable.

Monarchial Coup d'état of 1772.

Abroad the Swedish revolution made a great sensation. Catherine II. of Russia saw in it the triumph of her arch-enemy France, with the prolongation of the costly Turkish War as its immediate result. But the absence of troops on the Finnish border, and the bad condition of the frontier fortresses, constrained the empress to listen to Gustavus's pacific assurances, and stay her hand. She took the precaution, however, of concluding a fresh secret alliance with Denmark, in which the Swedish revolution was significantly described as "an act of violence" constituting a *casus foederis*, and justifying both powers in seizing the first favourable opportunity for intervention to restore the Swedish constitution of 1720.

In Sweden itself the change was, at first, most popular. But Gustavus's first Riksdag, that of 1778, opened the eyes of the deputies to the fact that their political supremacy had departed. The king was now their sovereign lord; and, for all his courtesy and gentleness, the jealousy with which he guarded and the vigour with which he enforced the prerogative plainly showed that he meant to remain so. But it was not till after eight years more had elapsed that actual trouble began. The Riksdag of 1778 had been obsequious; the Riksdag of 1786 was mutinous. It rejected nearly all the royal measures outright, or so modified them that Gustavus himself withdrew them. When he dismissed the estates, the speech from the throne held out no prospect of their speedy revocation.

Nevertheless, within three years, the king was obliged to summon another Riksdag, which met at Stockholm on the 26th of January 1789. His attempt in the interval to rule without a parliament had been disastrous. It was only by a breach of his own constitution that he had been able to declare war against Russia (April 1788); the conspiracy of Anjala (July) had paralysed all military operations at the very opening of the campaign; and the sudden invasion of his western provinces by the Danes, almost simultaneously (September), seemed to bring him to the verge of ruin. But the contrast, at this crisis, between his self-sacrificing patriotism and the treachery of the Russophil aristocracy was so striking that, when the Riksdag assembled, Gustavus found that the three lower estates were ultra-royalist, and with their aid he succeeded, not without running great risks (see GUSTAVUS III.; NORDIN, GUSTAF; WALLQVIST, OLAF), in crushing the opposition of the nobility by a second *coup d'état* (Feb. 16, 1789), and passing the famous Act of Union and Security which gave the king an absolutely free hand as regards foreign affairs and the command of the army, and made further treason impossible. For this the nobility never forgave him. It was impossible, indeed, to resist openly so highly gifted and so popular a sovereign; it was only by the despicable expedient of assassination that the last great monarch of Sweden was finally removed, to the infinite detriment of his country.

The Act of Union and Security, 1789.

The ensuing period was a melancholy one. The aristocratic classes loudly complained that the young king, Gustavus IV., still a minor, was being brought up among crypto-Jacobins; while the middle classes, deprived of the stimulating leadership of the anti-aristocratic "Prince Charming," and becoming more and more inoculated with French political ideas, drifted into an antagonism not merely to hereditary nobility, but to hereditary monarchy likewise. Everything was vacillating and uncertain; and the general instability was reflected even in foreign affairs, now that the master-hand of Gustavus III. was withdrawn. The renewed efforts of Catherine II. to interfere in Sweden's domestic affairs were, indeed, vigorously repulsed, but without tact or discretion, so that the good understanding between the two countries was seriously impaired, especially when the proclivities of Gustaf Reuterholm (*q.v.*), who then virtually ruled Sweden, induced him to adopt what was generally considered an indecently friendly attitude towards the government at Paris. Despite the execution of Louis XVI. (Jan. 21, 1793), Sweden, in the hope of obtaining considerable subsidies, recognized the new French republic; and secret negotiations for contracting an alliance were actually begun in May of the same year, till the menacing protests of Catherine, supported as they were by all the other European powers, finally induced Sweden to suspend them.

Gustavus IV., 1792–1809.

Sweden and Revolutionary France.

The negotiations with the French Jacobins exacerbated the hatred which the Gustavians already felt for the Jacobin councillors of the duke-regent (see CHARLES XIII., king of Sweden). Smarting beneath their grievances and seriously believing that not only the young king's crown but his very life was in danger, they formed a conspiracy, the soul of which was Gustaf Mauritz Armfelt (*q.v.*), to overthrow the government, with the aid of a Russian fleet, supported by a rising of the Dalecarlians. The conspiracy was discovered and vigorously suppressed.

The one bright side of this gloomy and sordid period was the *rapprochement* between the Scandinavian kingdoms during the revolutionary wars. Thus, on the 27th of March 1794, a neutrality compact was formed between Denmark and Sweden; and their united squadrons patrolled the North Sea to protect their merchantmen from the British cruisers. This approximation between the two governments was happily followed by friendly feelings between the two nations, under the pressure of a common danger. Presently Reuterholm renewed his coquetry with the French republic, which was officially recognized by the Swedish government on the 23rd of April 1795. In return, Sweden received a subsidy of £56,000; and a treaty between the two powers was signed on the 14th of September 1795. On the other hand, an attempt to regain the friendship of Russia, which had broken off diplomatic relations with Sweden, was frustrated by the refusal of the king to accept the bride, the grand duchess Alexandra, Catherine II.'s granddaughter, whom Reuterholm had provided for him. This was Reuterholm's last official act. On the 1st of November 1796, in accordance with the will of his father, Gustavus IV., now in his eighteenth year, took the government into his own hands.

Alliance with Denmark.

The government of Gustavus IV. (*q.v.*) was almost a pure autocracy. At his very first Riksdag, held at Norrköping in March 1800, the nobility were compelled, at last, to ratify Gustavus III.'s detested Act of Union and Security, which hitherto they had steadily refused to do. Shortly after this Riksdag rose, a notable change took place in Sweden's foreign policy. In December 1800 Denmark Sweden and Russia acceded to a second Armed Neutrality of the North, directed against Great Britain; and the arsenal of Karlskrona, in all probability, was only saved from the fate of Copenhagen by the assassination of the emperor Paul, which was followed by another change of system in the north. Hitherto Sweden had kept aloof from continental complications; but the arrest and execution of the duc d'Enghien in 1804 inspired Gustavus IV. with such a hatred of Napoleon that when a general coalition was formed against the French emperor he was one of the first to join it (Dec. 3, 1804), pledging himself to send an army corps to co-operate with the English and Russians in driving the enemy out of Holland and Hanover. But his senseless quarrel with Frederick William III. of Prussia detained him in Pomerania; and when at last (December 1805) he led his 6000 men towards the Elbe district the third coalition had already been dissipated by the victories of Ulm and Austerlitz. In 1806 a rupture between Sweden and Prussia was only prevented by Napoleon's assault upon the latter power. After Jena Napoleon attempted to win over Sweden, but Gustavus rejected every overture. The result was the total loss of Pomerania, and the Swedish army itself was only saved from destruction by the ingenuity of J. K. Toll (*q.v.*).

Gustavus IV. joins the European Coalition, 1804.

At Tilsit the emperor Alexander I. had undertaken to compel "Russia's geographical enemy," as Napoleon designated Sweden, to accede to the newly established Continental System. Gustavus IV. naturally rejected all the proposals of Alexander to close the Baltic against the English; but took no measures to defend Finland against Russia, though, during the autumn of 1807, it was notorious that the tsar was preparing to attack the grand duchy. On the 21st of February 1808 a Russian army crossed the Finnish border without any previous declaration of war. On the 2nd of April the king ordered a general levy of 30,000 men; but while two army corps, under Armfelt and Toll, together with a British contingent of 10,000 men under Moore, were stationed in Scania and on the Norwegian border in anticipation of an attack from Denmark, which, at the instigation of Napoleon, had simultaneously declared war against Sweden, the little Finnish army was left altogether unsupported. The conquest of Finland, after

Russian Conquest of Finland, 1808.

an heroic struggle against overwhelming odds, is elsewhere recorded (see FINLAND: *History*). Its immediate consequence in Sweden proper was the deposition of Gustavus IV. (March 13, 1809), who was clearly incapable of governing.

Deposition of Gustavus IV., 1809.

The nobility took advantage of this opportunity to pay off old scores against Gustavus III. by excluding not only his unhappy son but also that son's whole family from the succession—an act of injustice which has never been adequately defended. But indeed the whole of this intermediate period is full of dark subterranean plots and counterplots, still inexplicable, as, for instance, the hideous Fersen murder (June 20, 1810) (see FERSEN, HANS AXEL VON) evidently intended to terrorize the Gustavians, whose loyalty to the ancient dynasty was notorious. As early as the 5th of June 1809 the duke regent was proclaimed king, under the title of Charles XIII. (*q.v.*), after accepting the new liberal constitution, which was ratified by the Riksdag the same day.

Charles XIII., 1809–1819.

The new king was, at best, a useful stopgap, in no way likely to interfere with the liberal revolution which had placed him on the throne. Peace was what the exhausted nation now required; and negotiations had already been opened at Fredrikshamn. But the Russian demands were too humiliating, and the war was resumed. But the defeats of Sävarsbruk and Ratan (Aug. 19, 1809) broke the spirit of the Swedish army; and peace was obtained by the sacrifice of Finland, the Åland islands, "the fore-posts of Stockholm," as Napoleon rightly described them, and Vesterbotten as far as the rivers Torneå and Muonio (treaty of Fredrikshamn, Sept. 17, 1809).

The succession to the throne, for Charles XIII. was both infirm and childless, was settled, after the mysterious death (May 28, 1810) of the first elected candidate, Prince Charles Augustus of Augustenburg, by the selection of the French marshal, Bernadotte (see CHARLES XIV., king of Sweden), who was adopted by Charles XIII. and received the homage of the estates on the 5th of November 1810.

Bernadotte chosen as Crown Prince.

The new crown prince was very soon the most popular and the most powerful man in Sweden. The infirmity of the old king, and the dissensions in the council of state, placed the government and especially the control of foreign affairs almost entirely in his hands; and he boldly adopted a policy which was antagonistic indeed to the wishes and hopes of the old school of Swedish statesmen, but, perhaps, the best adapted to the circumstances. Finland he at once gave up for lost. He knew that Russia would never voluntarily relinquish the grand duchy, while Sweden could not hope to retain it permanently, even if she reconquered it. But the acquisition of Norway might make up for the loss of Finland; and Bernadotte, now known as the crown prince Charles John, argued that it might be an easy matter to persuade the anti-Napoleonic powers to punish Denmark for her loyalty to France by wresting Norway from her. Napoleon he rightly distrusted, though at first he was obliged to submit to the emperor's dictation. Thus on the 13th of November 1810, the Swedish government was forced to declare war against Great Britain, though the British government was privately informed at the same time that Sweden was not a free agent and that the war would be a mere demonstration. But the pressure of Napoleon became more and more intolerable, culminating in the occupation of Pomerania by French troops in 1812. The Swedish government thereupon concluded a secret convention with Russia (treaty of Petersburg, April 5, 1812), undertaking to send 30,000 men to operate against Napoleon in Germany in return for a promise from Alexander guaranteeing to Sweden the possession of Norway. Too late Napoleon endeavoured to outbid Alexander by offering to Sweden Finland, all Pomerania and Mecklenburg, in return for Sweden's active co-operation against Russia.

Influence and Policy of Bernadotte.

The Orebro Riksdag (April–August 1812), remarkable besides for its partial repudiation of Sweden's national debt and its reactionary press laws, introduced general conscription into Sweden, and thereby enabled the crown prince to carry out his ambitious policy. In May 1812 he mediated a peace between Russia and Turkey, so as to enable Russia to use all her forces against France (peace of Bucharest); and on the 18th of July, at Örebro, peace was also concluded between Great Britain on one side and Russia and Sweden on the other. These two treaties were, in effect, the corner-stones of a fresh coalition against Napoleon, and were confirmed on the outbreak of the Franco-Russian War by a conference between Alexander and Charles John at Åbo on the 30th of August 1812, when the tsar undertook to place an army corps of 35,000 men at the disposal of the Swedish crown prince for the conquest of Norway.

The treaty of Åbo, and indeed the whole of Charles John's foreign policy in 1812, provoked violent and justifiable criticism among the better class of politicians in Sweden. The immorality of indemnifying Sweden at the expense of a weaker friendly power was obvious; and, while Finland was now definitively sacrificed, Norway had still to be won. Moreover, Great Britain and Russia very properly insisted that Charles John's first duty was to the anti-Napoleonic coalition, the former power vigorously objecting to the expenditure of her subsidies on the nefarious Norwegian adventure before the common enemy had been crushed. Only on his very ungracious compliance did Great Britian also promise to countenance the union of Norway and Sweden (treaty of Stockholm, March 3, 1813); and, on the 23rd of April, Russia gave her guarantee to the same effect. The Swedish crown prince rendered several important services to the allies during the campaign of 1813 (see CHARLES XIV., king of Sweden); but, after Leipzig, he went his own way, determined at all hazards to cripple Denmark and secure Norway.

How this "job" was managed contrary to the dearest wishes of the Norwegians themselves, and how, finally (Nov. 14, 1814), Norway as a free and independent kingdom was united to Sweden under a common king, is elsewhere described (see DENMARK; NORWAY; CHARLES XIV., king of Sweden; CHRISTIAN VIII., king of Denmark).

Union with Norway.

Charles XIII. died on the 5th of February 1818, and was succeeded by Bernadotte under the title of Charles XIV. John. The new king devoted himself to the promotion of the material development of the country, the Göta canal absorbing the greater portion of the twenty-four millions of dalers voted for the purpose. The external debt of Sweden was gradually extinguished, the internal debt considerably reduced, and the budget showed an average annual surplus of 700,000 dalers. With returning prosperity the necessity for internal reform became urgent in Sweden. The antiquated Riksdag, where the privileged estates predominated, while the cultivated middle class was practically unrepresented, had become an insuperable obstacle to all free development; but, though the Riksdag of 1840 itself raised the question, the king and the aristocracy refused to entertain it. Yet the reign of Charles XIV. was, on the whole, most beneficial to Sweden; and, if there was much just cause for complaint, his great services to his adopted country were generally acknowledged. Abroad he maintained a policy of peace based mainly on a good understanding with Russia.

Charles XIV., 1818–1844.

Charles XIV.'s son and successor King Oscar I. was much more liberally inclined. Shortly after his accession (March 4, 1844) he laid several projects of reform before the Riksdag; but the estates would do little more than abolish the obsolete marriage and inheritance laws and a few commercial monopolies. As the financial situation necessitated a large increase of taxation, there was much popular discontent, which culminated in riots in the streets of Stockholm (March 1848). Yet, when fresh proposals for parliamentary reform were laid before the Riksdag in 1849, they were again rejected by three out of the four estates. As regards foreign politics, Oscar I. was strongly anti-German. On the outbreak of the Dano-Prussian War of 1848–49, Sweden sympathized warmly with Denmark. Hundreds of Swedish volunteers hastened to Schleswig-Holstein. The Riksdag voted 2,000,000 dalers for additional armaments. It was Sweden, too, who mediated the truce of Malmö (Aug. 26, 1848), which

Oscar I., 1844–1859.

helped Denmark out of her difficulties. During the Crimean War Sweden remained neutral, although public opinion was decidedly anti-Russian, and sundry politicians regarded the conjuncture as favourable for regaining Finland.

Charles XV., 1859–1872.

Oscar I. was succeeded (July 8, 1859) by his son, Charles XV. (*q.v.*), who had already acted as regent during his father's illnesses. He succeeded, with the invaluable assistance of the minister of justice, Baron Louis Gerhard de Geer (*q.v.*), in at last accomplishing the much-needed reform of the constitution. The way had been prepared in 1860 by a sweeping measure of municipal reform; and, in January 1863, the government brought in a reform bill by the terms of which the Riksdag was henceforth to consist of two chambers, the Upper House being a sort of aristocratic senate, while the members of the Lower House were to be elected triennially by popular suffrage. The new constitution was accepted by all four estates in 1865 and promulgated on the 22nd of January 1866. On the 1st of September 1866, the first elections under the new system were held; and on the 19th of January 1867, the new Riksdag met for the first time. With this one great reform Charles XV. had to be content; in all other directions he was hampered, more or less, by his own creation. The Riksdag refused to sanction his favourite project of a reform of the Swedish army on the Prussian model, for which he laboured all his life, partly from motives of economy, partly from an apprehension of the king's martial tendencies. In 1864 Charles XV. had endeavoured to form an anti-Prussian league with Denmark; and after the defeat of Denmark he projected a Scandinavian union, in order, with the help of France, to oppose Prussian predominance in the north—a policy which naturally collapsed with the overthrow of the French Empire in 1870. He died on the 18th of September 1872, and was succeeded by his brother, the duke of Gothland, who reigned as Oscar II. (R. N. B.)

Constitutional Reform, 1866.

Oscar II., 1872–1907.

The economic condition of Sweden, owing to the progress in material prosperity which had taken place in the country as the result of the Franco-German War, was at the accession of Oscar II. to the throne on the 18th of September 1872 fairly satisfactory. Politically, however, the outlook was not so favourable. In their results, the reforms inaugurated during the preceding reign did not answer expectations. Within three years of the introduction of the new electoral laws De Geer's ministry had forfeited much of its former popularity, and had been forced to resign. In the vital matter of national defence no common understanding had been arrived at, and during the conflicts which had raged round this question, the two chambers had come into frequent collision and paralysed the action of the government. The peasant proprietors, who, under the name of the "Landtmanna" party,[1] formed a compact majority in the Second Chamber, pursued a consistent policy of class interests in the matter of the taxes and burdens that had, as they urged, so long oppressed the Swedish peasantry; and consequently when a bill was introduced for superseding the old system of army organization by general compulsory service, they demanded as a condition of its acceptance that the military burdens should be more evenly distributed in the country, and that the taxes, which they regarded as a burden under which they had wrongfully groaned for centuries, should be abolished. In these circumstances, the "Landtmanna" party in the Riksdag, who desired the lightening of the military burden, joined those who desired the abolition of landlordism, and formed a compact and predominant majority in the Second Chamber, while the burgher and Liberal parties were reduced to an impotent "intelligence" minority. This majority in the Lower Chamber was at once attacked by another compact majority in the Upper, who on their side maintained that the hated land taxes were only a kind of rent-charge on land, were incidental to it and in no way weighed upon the owners, and, moreover, that its abolition would be quite unwarrantable, as it was one of the surest sources of revenue to the state. On the other hand, the First Chamber refused to listen to any abolition of the old military system, so long as the defence of the country had not been placed upon a secure basis by the adoption of general compulsory military service. The government stood midway between these conflicting majorities in the chambers, without support in either.

[1] The Swedish "Landtmanna" party was formed in 1867. It consisted mostly of the larger and smaller peasant proprietors, who at the time of the old "Standers Riksdag" were always opposed to the nobility and the clergy. The object of the party was to bring about a fusion between the representatives of the large landed proprietors and the regular peasant proprietors, to support the interests of landed proprietors in general against those of the town representatives, and to resist Crown interference in the administration of local affairs.

The Party Compromise of 1874.

Such was the state of affairs when Oscar II., surrounded by his late brother's advisers, began his reign. One of his first cares was to increase the strength of his navy, but in consequence of the continued antagonism of the political parties, he was unable to effect much. In the first Riksdag, however, the so-called "compromise," which afterwards played such an important part in Swedish political life, came into existence. It originated in the small "Scania" party in the Upper House, and was devised to establish a *modus vivendi* between the conflicting parties, *i.e.* the champions of national defence and those who demanded a lightening of the burdens of taxation. The king himself perceived in the compromise a means of solving the conflicting questions, and warmly approved it. He persuaded his ministers to constitute a special inquiry into the proposed abolition of land taxes, and in the address with which he opened the Riksdag of 1875 laid particular stress upon the necessity of giving attention to the settlement of these two burning questions, and in 1880 again came forward with a new proposal for increasing the number of years of service with the militia. This motion having been rejected, De Geer resigned, and was succeeded by Count Arvid Posse. The new prime minister endeavoured to solve the question of defence in accordance with the views of the "Landtmanna" party. Three parliamentary committees had prepared schemes for a remission of the land taxes, for a new system of taxation, for a reorganization of the army based on a *stammtrupp* (regular army), by the enlistment of hired soldiers, and for naval reforms. In this last connexion the most suitable types of vessels for coast defence as for offence were determined upon. But Count Posse, deserted by his own party over the army bill, resigned, and was succeeded on the 16th of May 1884 by Oscar Themptauder, who had been minister of finance in the previous cabinet. The new premier succeeded in persuading the Riksdag to pass a bill increasing the period of service with the colours in the army to six years and that in the militia to forty-two days, and as a set-off a remission of 30% on the land taxes.

Protectionist Movement.

Influenced by the economic reaction which took place in 1879 in consequence of the state of affairs in Germany, where Prince Bismarck had introduced the protectionist system, a protectionist party had been formed, which tried to gain adherents in the Riksdag. It is true that in the Riksdag of 1882 the commercial treaty with France was renewed, but since 1885 the protectionist party was prepared to begin the combat, and a duty on corn, which had been proposed in the Riksdag of the same year, was rejected by only a slight majority. During the period of the unusually low price of corn of 1886, which greatly affected the Swedish farmers, protection gained ground to such an extent that its final triumph was considered as certain within a short time. During the Riksdag of the same year, however, the premier, Themptauder, emphatically declared himself against the protectionist party, and while the parties in the Second Chamber were equal in number, the proposed tax on corn was rejected in the First Chamber. In the Riksdag of 1887 there was a majority for protection in the Second Chamber, and in the first the majority against the tax was so small that the tax on corn would have triumphed in a combined meeting of the two chambers. The government, availing itself of its formal right not to dissolve the chamber in which it had the support of a majority, therefore dissolved only the Second Chamber (March 1887).

The new Riksdag assembled in May with a free trade majority in the Second Chamber, but nothing in connexion with the great question of customs was settled. In the meantime, the powerful majority in the Second Chamber split into two groups—the new "Landtmanna" party, which approved protection in the interests of agricultural classes; and a somewhat smaller group, the old "Landtmanna" party, which favoured free trade.
